By Sir **WILLIAM WHITLA**, M.D., D.Sc., LL.D., M.P., Emeritus Professor of Materia Medica and Therapeutics in Queen's University, Belfast; Hon. Physician in Ordinary to H.M. the King in Ireland; Consulting Physician to Royal Victoria, Belfast Ophthalmic, and the Ulster Hospitals for Women and Children. London: Baillière, Tindall and Cox. 1923. Pp. 1100. 25*s*.

THAT seven editions of this work have appeared is testimony to its abundant popularity, but whether the condensation of the treatment of all medical, surgical, and gynæcological conditions into a single volume is any longer possible has become a debatable matter. It is inevitable that in such a work there must appear many statements which readers specially experienced in one branch of medicine must receive with reservation. That is not a serious matter while the principles are generally accepted unless omissions occur which obscure the principles. Some of the recommendations which appear in this edition will be challenged to-day—we may refer to the article on diabetes, in which, in spite of ample reference to the discovery of insulin, the clinical and laboratory tests given have been supplanted, and the diet much criticised, if not condemned. Under chronic dysentery there seems no mention of emetine as a possible specific treatment, and the mention of quinidine in the treatment of auricular fibrillation is dangerous in its brevity. It would be easy to multiply examples of the same nature; to do so would be to give a false impression of what is, in many respects, an accumulation of much wisdom included in a volume whose popularity is well deserved. Will not Prof. Whitl simplify and condense this work in a new edition The advice seems to contradict remarks directe against omissions, but the omissions could be rectifie if the space were found by rigorous deletion of th matter which is no longer accepted, or only hal proved.

KLINISCHE LABORATORIUMSTECHNIK.

I. Band. Herausgegeben von Prof. **THEODO BRUGSCH** und Prof. **A. SCHITTENHELM**. Berli and Vienna: Urban und Schwarzenberg. 192 Pp. 681.

THIS is the second edition of a handbook on clinic methods. The original first edition was issued und a different title: "Technik der Speciellen Klinische Untersuchungsmethoden." Three volumes are pr jected for this second edition, of which the volum under review is the first. It deals with the followin subjects: measurements of the body; estimation blood volume; total hæmoglobin and minute volum of the heart; the electrocardiograph; the registratio of arterial and venous pulse and of the heart sounds registration of respiratory movements; X ray tec nique, bacteriological technique, histological techniqu various optical apparatus (spectroscope, polarimete colorimeter, dark-ground illumination), and th technique of metabolism experiments.

The various chapters are competently writte but it is not easy to see the advantage of assemblin in a bulky volume such heterogeneous materia The bacteriologist is not likely to be interested in th technique of the electrocardiograph or the metho of registering the cardiac sounds. For most of th subjects dealt with in this volume numerous mo exhaustive monographs are already available, and would have been preferable if the material collect in this volume had also been issued separately in th form of monographs.

HIGH-FREQUENCY PRACTICE.

Second edition. By **BURTON BAKER GROVE** M.D., Fellow of the American Electrotherapeut Association, &c. London: Chapman and Hal Ltd. 1923. Pp. 399. 21*s*.

THIS book begins with an introductory chapt entitled "What is Electricity?" In this chapter a discussed the nature of electricity and light, th theories of atoms and electrons, &c. Next the natu and production of high-frequency currents a explained and various methods of applying the Chapters follow on medical diathermy and surgic diathermy and deal with the uses of high-frequen for the production of heat within the body. Blo pressure in health and disease and the influence high-frequency currents on it are next noticed a pain is defined; a classification of pains is given a the clinical significance of pain in various regio is discussed. In Chapter VII., the longest in the boo containing 140 pages, the treatment by high-frequen of over 80 diseases and morbid conditions is describe The treatment of diseases of the eye by the sa means is considered in the next section. The auth recommends the use of high-frequency and describ its application for cases of inflammation of the co junctiva and cornea, for corneal opacities, iriti glaucoma, cataract, optic atrophy, toxic amblyopi and certain diseases of the lids. The book conclud with two appendices and a glossary. The fir appendix contains a number of questions, which w enable the physician to examine himself as to the sta of his knowledge of high-frequency. The seco contains the author's presidential address to th Western Electro-Therapeutic Association.

After a perusal of this book the impression is gain that high-frequency currents have some physiologic and therapeutic action other than that due to th production of heat in the body. The author stat that the physiological action of these currents vari with the type of apparatus, but he does not s whether different types of apparatus differ in th amount of heat which their currents produce in the body. The physiological actions of high-frequency currents on them are described for the different organs. It is said that "splanchnic stasis is relieved through a general stabilisation of the circulation." The secretion of the pancreas is stated to be "influenced in some unknown manner which results in decreased output of sugar in the urine." Under the heading of the spleen we read: "The reflex of contraction and dilatation may be incited through spinal application, thus in a limited manner controlling certain infections. Direct application favours the freeing of specific bacteria which enter the circulation causing recurrence of malady." Diathermy is described in two separate chapters and the idea is conveyed that it is a special branch of high-frequency therapy.

Although he will not agree with many of the statements made on physics and physiology, the English specialist in electro-therapeutics will find much that will interest him in this book. It is humorously written in parts. In the treatment of headache the author says that above all things the route which leads to the acetanilid shelf should be avoided. "Americanitis," he says, is one of the ætiological factors in neurasthenia.

OBSTETRIC TABLES.

A Guide for Students. Second edition. By MAURICE G. ANDERSON, L.R.C.P. Edin. London: A. and C. Black. 1923. Pp. 111. 3*s.* 6*d.*

THESE tables are intended for the use of students as a help in revising their work. The arrangement is good and no doubt they fill a useful function. We cannot, however, regard them as typical of modern teaching on this subject. For example, under the treatment of placenta prævia no mention is made of the use of a hydrostatic dilator, often one of the most successful methods of treatment, and in discussing the treatment of accidental hæmorrhage nothing is said for the necessity of Cæsarean section in some of these cases, while of plugging the vagina Dr. Anderson says that it is often successful, but with the added risk of sepsis. The average length of time required for the induction of labour by Krause's method is 84 not 12 hours.

PUERPERAL FEVER AND ITS PROPHYLAXIS.

By EUSTACE THORP, O.B.E., L.R.C.S., L.R.C.P., D.P.H., Assistant Medical Officer of Health, Sunderland; Medical Officer, Sunderland Borough Sanatorium. Bristol: John Wright and Sons. 1922. Pp. 48. 2*s.* 6*d.*

THIS little brochure contains an account of a series of small epidemics of puerperal septicæmia occurring in an institution.

Early in the year a septic case was notified; this was followed by a case of scarlet fever and these by five other cases of scarlet fever complicated by fairly severe septicæmia; there were two deaths. Disinfection having been thoroughly carried out cases ran normally until an emergency septic case was admitted and from this case 11 other women showed signs of infection; five were seriously ill, two fairly ill, and three sapræmic. There were no deaths. From his experience in these and other cases the author has written an eminently readable account of the chief features of this disease.

THE VILLEMIN HOSPITAL.

Un hôpital militaire à Paris pendant la guerre: Villemin, 1914–1919. Par F. LEJARS. Paris: Masson et Cie. 1923. Pp. 364. Fr.10.

M. Lejars is professor of clinical surgery in the Paris Faculty of Medicine and was during the war chief medical officer of the hospital about which he has written a book. He has given us a really charming work. Some philosopher has said that "there is something not altogether unpleasing in the misfortunes of our best friends," and when we recollect the strain which was felt by our medical establishments during the early days of the war, it is cheering to read Prof. Lejars's account of the Villemin Hospital. The building was old and had been *déclassé* for some 30 years. It was started in a secularised convent belonging to the Recollets (an order of reformed Franciscans) during the Revolution, and in 1860 was handed over by the Assistance Publique to the War Office as a military hospital, and refitted and enlarged under the name of l'Hôpital St. Martin. In 1913 its name was changed to that of l'Hôpital Militaire Villemin, in honour of the famous Jean Antoine Villemin, 1827–1892, who had proved in 1868 that the virus of tubercle is specific and inoculable. For all that the building had been condemned so far back as 1892, and was only a hospital in name, "*à titre provisoire*" while awaiting a successor. Threatened men live long, says our English proverb, and as Prof. Lejars remarks, "*le 'provisoire' est une des meilleures conditions de durée.*" Though *déclassé*, the hospital did receive patients into its 556 beds, the average annual numbers in the five years preceding the war being something over 2000. On August 2nd, 1914, various medical men, mainly civilians who were too old to go to the front, joined at the Villemin Hospital, most of them, including Prof. Lejars himself, as he openly confesses, entirely ignorant of any military service. The first chief medical officer was Gaucher, to whose memory Prof. Lejars pays a warm tribute —he died, worn out, on Jan. 25th, 1918. During the period August 2nd, 1914, to June 6th, 1919, 30,546 patients of all ranks were treated in the hospital, with a mortality of 847. The trials, struggles, and successes of the hospital must be read in Prof. Lejars's pages; suffice it to say admirable work was done by the devoted staff, and neither "Big Berthas" nor the attacks of aeroplane bombers could shake their courage. Prof. Lejars concludes with some reflections which are well worth reading as to the absolute necessity "for fusion and intimate collaboration, for the good of the service and of the country, between the (medical) officers of the active staff and those of the reserve (*complément*)."

ANATOMY.

Text-book on the Artistic Anatomy of the Human Form. By U. W. A. PARKES, Lecturer on Artistic Anatomy at St. John's Wood Art Schools. London: John Bale, Sons, and Danielsson, Ltd. 1923. Pp. 127. 10*s.*

EVEN to the professional anatomist there is a certain amount of interest in encountering the commonplaces of human anatomy under conditions differing from those to which he is accustomed. This book presents the skeleton and many of the muscles from the point of view of the artist, concerned with their bearing on the outer form. It is illustrated, mostly by the author's own competent pencil, to show how the structures he describes affect the surface appearances. The result is the presentation of unusual anatomical values, the whole done in a short and readable form. It is in no spirit of hypercriticism that we call the author's attention to a few anatomical errors. Thus, subcutaneous fat is not under the investing fascia, nor does this latter enclose the rectus abdominis; the action of the trapezius might be revised—as, indeed, might the account of the mechanism of raising the shoulder, apart from the analysis of this movement. Again, in some of the figures, certain changes might be effected in future issues: in the male skeleton, in the figure on p. 11, the upper end of the radius appears to be in full supination, while the hand, and seemingly the lower end of the radius, are semi-pronated; the drawing of the serratus magnus muscle gives it an origin from the ninth rib, although the account given in the text is the one usually accepted. Such errors, though it would be better if they had not occurred, hardly detract from the value which this book will have, we expect, in the eyes of students of artistic anatomy. A short and clear account is given of the distribution of weight by the skeleton, and we would suggest that this theme might be enlarged upon and made into a standpoint from which the artist could view the effect of any action on even the most distant parts of the body, and hence on its form; yet perhaps this would be foreign to the idea of the author and would tend to widen the scope of the book too much. The work is well produced in every way.

Gray's Anatomy. Twenty-second edition. Edited by ROBERT HOWDEN. London: Longmans, Green and Co. 1923. Pp. 1378. 42*s.*

A BOOK which has passed into its twenty-second edition may be considered to be beyond criticism. Prof. Howden's able editorship during the last 20 years has made "Gray" what it is to-day, an English text-book of anatomy second to none. A good feature of the work to English or British eyes for many years has been the prominence justly given to work done at home, and in this matter the present edition has not fallen behind its predecessors. It is thoroughly up-to-date. Gray's Anatomy has always been a favourite with English students, and the oldest among us remember it as a sheet-anchor when at sea in early days; if we regret the change in nomenclature which has been adopted, it does not lessen our affection for the book, though it may affect the frequency of our consultations. The present edition has some 60 new figures and has been revised in general, and is worthy of the place of honour it occupies.

AIDS TO PUBLIC HEALTH.

By W. G. AITCHISON ROBERTSON, M.D. London: Baillière, Tindall and Cox. 1923. Pp. 160. 3*s.* 6*d.*

THIS volume is designed to refresh the memory of the student as to the main facts in the various subjects in public health, and the useful rôle has been fulfilled. The book makes the usual survey of hygiene and public health, successive chapters dealing with meteorology, air ventilation and heating, water-supply, house sanitation, drainage, disposal of sewage, house and hospital construction, food, disinfection, infection, infectious diseases, the soil and disposal of the dead, diseases due to occupation, schools and medical inspection, vital statistics, and sanitary administration. The summary of these subjects which can be made in 160 pages is necessarily sketchy and such curtailment of statements implies not only omissions of important matter, but also the inclusion of statements which need expansion and even modification to render them useful and accurate. Assuming, however, that the student has studied larger volumes, and above all has engaged in the various branches of public health work, he will find the volume useful.

RADIOACTIVITY.

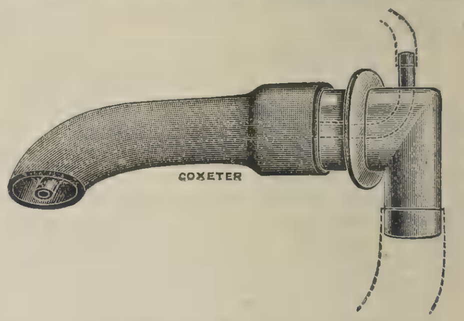
By KASIMIR FAJANS. Translated from the fourth German edition by T. S. WHEELER, B.Sc., A.R.C.Sc.I., A.I.C., and W. G. KING. London: Methuen and Co., Ltd. 1923. Pp. 138. 8*s.* 6*d.*

Prof. Fajans's book has been well known to specialist workers in physics and chemistry, and such will welcome the translation, as it will present an extremely readable account of radioactivity and cognate lines of work to a much wider circle of readers. It may be said at once that, although hardly a literal translation, the enthusiasm of Fajans for this branch of work, so apparent in the original German, is not lost in the English edition. The wonderful developments which have taken place since Becquerel's discovery of radioactivity in 1896, including the isolation of radium and other radioactive substances, the transformation products, and their position in relation to the ordinary chemical elements in the periodic table, are described. The nature of isotropes, both those whose origin can be traced as degradation products of radioactive elements and those which have been shown by positive ray analysis to occur in common elements, and the effect of these discoveries on chemical theory, are dealt with in a most lucid manner. The nature of the atom, the decomposition of some atoms by rapidly moving particles, such as X rays, follow as a natural sequence to the earlier chapters. Although so brief a time has elapsed since the first experimental observations were made in this field, it is remarkable that the story as presented in this book should be so consecutive, and also gratifying that results of such great importance should be published in a form that anyone with only a slight knowledge of physics and chemistry can benefit. The specialist will find the numerous references to original papers and the notes given at the end of the book invaluable.

New Inventions.

IMPROVED ANÆSTHETIC APPARATUS.

Two small modifications of everyday anæsthetic apparatus have proved useful and may be of interest. 1. An improved airway which, as shown by the illustration, consists of an ordinary airway of the Phillips type, to the mouth-piece of which is fitted a removable and reversible metal elbow-piece similar to Clayton's, and of only sufficient length to afford firm attachment to a thick-walled rubber tube of $\frac{1}{2}$-in. bore.



A narrow bore angular tube is fitted into this elbow so that its outer end forms a nipple for attaching to the delivery tube of any anæsthetic apparatus, the inner end being prolonged within the airway by a thin rubber tube of nearly equal length. When used with chloroform from a Junker, a short length of rubber tube of wide bore may be attached to carry away the anæsthetic vapour from the operation area—e.g., in ophthalmic operations. By increasing the length of this tube a degree of re-breathing may be obtained, whilst when gas and oxygen is used a bag is attached to the end of the tube. The small bag from a Clover's apparatus has usually been used, with the tap open to serve as a blow off; it is connected up with a special adapter and clipped in a convenient position at the edge of or below the table.

2. A modified three-way (Barth's) gas-valve. The passages through this valve are, as a rule, rather narrow, but when in the usual position for gas and oxygen administration—i.e., that giving a partial re-breathing—it will be seen that the available airway is much restricted by the rotating septum to which the inner (inspiratory) valve is fixed. Further, if left wet this valve is liable to stick. In use, unless accurately adjusted and watched, the action of the valve causes emptying of the bag. The inspiratory valve has therefore been entirely removed, which permits of all openings being enlarged. In use, the amount of re-breathing depends on the rate of flow of the gases, the bag being always filled by expiration. The escape of expiratory gases from the bag is controlled by the degree of closure of the expiratory valve only, an additional "click" being provided to keep this valve in its usual working position—i.e., about half closed. In addition, an adjustable elbow is fitted over the expiratory valve mounting, and carries away expired gases by a rubber tube below the table.

The makers are Messrs. Coxeter and Son, Pancras-road, London, N.W.

London, N.W. R. J. CLAUSEN, M.B., B.S. Lond.

THE LANCET.

LONDON: SATURDAY, OCTOBER 27, 1923.

THE PRINCIPLE OF THE THING.

"While willing to serve the community to the best of its ability, and to make any satisfactory arrangement to this end with the representatives of the community, the medical profession is not prepared to accept the position of being under the dominance or control of a particular section."

THE Panel Conference has met and has amply endorsed the statement of the issue in the present crisis contained in the above words. The words are those of the Insurance Acts Committee in the latest stage of the negotiations between the Minister of Health and practitioners working under the National Health Insurance Acts. The representatives of panel committees were unanimously willing, as the report of the Conference on p. 947 shows, to commit their constituents to a refusal of further service under the Acts rather than continue to serve under the conditions offered. The Minister, it appears, admits his reponsibility for the financial burden which is to be put on the community, but it seems to us that he hardly grasps the full responsibility placed upon him by Parliament for the nature of the services given in return. The medical profession looks, and rightly looks, to the Minister for protection against the unsympathetic attitude of approved society officials, who are clearly fighting for something more than their own autonomy. They desire, overtly or implicitly, control of the national insurance system as a whole, and of the medical benefit in particular, from control of which they were expressly excluded by the Act of 1911. Clause 14 (1) of this Act is so precise and categorical that it is hard to see how any doubt upon this point can have arisen. There is, we are confident, no inherent dislike on the part of doctors for approved societies or their officials, no desire to give them less than their due in administering sickness and additional benefits; there is, in fact, a cordial coöperation steadily growing up in the local working of the Acts. Our special commissioner (p. 951) bears testimony to this in the Manchester and Salford area. But the unreasoning rancour shown by some of these officials towards insurance practitioners as a group affords ground for suspicion and hesitation on the part of the medical profession. Dr. H. B. BRACKENBURY himself, who presided over a series of round-table conferences of all interests, and seemed at one time hopeful of an arrangement by consent, is now sadly convinced of the futility of such conference inasmuch as the public statements of some of these officials do not agree with their private undertakings.

It is this question of the outside control of insurance medical service which must now be decided once and for all. It is the real crux of the controversy and the reason and justification for the unanimous refusal by the Panel Conference of the terms offered by the Minister of Health. The tone of the conference was firm and restrained, and little doubt exists that its representatives can make good their undertaking to call in the resignations of the necessary proportion of the doctors on the panel. Faced with this evidence of solidarity the medical profession can await the outlook with confidence. The national insurance committees have never yet, as Sir WILLIAM GLYN-JONES points out (p. 961), risen to their full stature, but they are not going to stultify themselves by attempting to administer medical benefit with the scanty help of those who stand aside. Action has not been hasty on the part of the doctors. Prolonged efforts have been made on the professional side to rectify as far as possible the conditions complained of by approved society officials. The new regulations when (perhaps we should write "if") they are issued, will show how far the insurance medical service has been willing to go. Nevertheless, the societies insist upon a cheap service, and have taken upon themselves to discuss what the actual remuneration for this service shall be. Now it cannot be reiterated too often that the societies do not pay the doctors; they are the recipients, as trustees, of that portion of insurance funds allotted for sickness benefit and administrative expenses; they have nothing whatever to do with the medical benefit funds, and it may be feared that, should they attain the position to which they aspire, of administrators of the whole fund, they would gladly cut out the Ministry of Health whose regulations they have always found irksome.

This is the danger which the medical profession clearly envisages in 1923, as it did in 1911–12, and once again a firm stand is to be made. On matters medical the profession should and must be given a free hand. There is in existence adequate machinery to deal with delinquents in its own fold, and the new powers given to panel committees will enable them to exert a much tighter control on any who are slack or devoid of principle. Approved society officials have attacked the insurance medical service as a whole because of their local knowledge of the "black sheep," whose numbers must be small indeed, judging by the complaints which are substantiated. The present action of these officials would drive out of the service precisely the type of practitioner whose coöperation is necessary to maintain its standard. We believe that the approved societies will find it hard to convince the insured public that the community will gain by usurpation of the control which was refused to them in 1911. It is a misfortune which was foreseen and which yet could hardly have been avoided, that the Insurance Acts should create vested interests with great political power. The spirited action of the Panel Conference is likely to prevent this power from becoming a danger to the community. Unless doctors serving voluntarily under the Insurance Acts are allowed to give their service in accordance with the best traditions of their profession, they prefer to wash their hands completely of a system which is in peril of becoming derogatory to their calling. In any case they will find a way of serving the community.

PHYSIOLOGY AND SURGERY.

TRADITION dies a slow death and custom often remains the only basis for perpetuating a system which long ago should have been superseded by methods more in conformity with modern intellectual conceptions. The idea that surgery is primarily a mechanical art is ineradicably fixed in the minds of many who do not practise it, and, indeed, in some of those who do. Physiology has always been an applied science, and progress in it waits upon the advance of knowledge in other directions. The greatest service that can be done to physiology is the stimulation of research in such sciences as those of chemistry, physical chemistry, and pure physics. That surgery must always be based upon physiology, whilst physiology must derive benefit from the advance of surgery, is so clear to the thinking active surgeon that it is always a matter of amazement to him that the generally accepted training of the surgeon is not based more upon this conception of the interdependence of the two branches of knowledge.

Sir EDWARD SHARPEY SCHAFER, in the first Victor Horsley Memorial Lecture, which we print in full in this issue of THE LANCET, chose as his subject the relations of physiology and surgery, a subject peculiarly fitting for a lecture instituted to commemorate a surgeon of HORSLEY'S stamp. In his most stimulating address he shows how false is our belief in the adequacy of the training the surgeon obtains by a prolonged apprenticeship in the dissecting room. Nothing but the trammels of tradition have allowed a system to persist under which the physician graduates through the physiological laboratory whilst the surgeon is relegated to the dissecting room. Powerful though many of the remedies of the physician are, the upset to normal physiology effected by the activities of the surgeon is, on the whole, enormously greater and infinitely more frequently brought about. Surgery, against all the dictates of scientific methods, seems usually to have worked backwards. Cachexia strumipriva had to result from complete removal of the thyroid before investigation of the functions of this gland took place; gastro-jejunostomy, introduced on a sound basis, was applied to relieve other conditions on assumptions which were afterwards proved actually to be totally wrong; whilst the large bowel was removed in man before the resulting changes in physiology brought about by its absence had been studied in animals. The wonderful power of adaptation possessed by the body has masked and remedied what otherwise would have been evil results. But much suffering might have been avoided if surgical problems had been tackled by the methods followed in other sciences. Sir EDWARD SHARPEY SCHAFER points out how our legislation hinders investigation in medicine and surgery. It is time to modify the dictum that anatomy is the basis of surgery. A correct knowledge of anatomy is as essential to the art of surgery as an acquaintance with Greek to the study of the classics. Each science has its own technique, the mastery of which is a necessity. There is a tendency to belittle the place of technique in surgery at the present time. Nothing could foster delay in progress more than this. The manual work of the surgeon must be as perfect as that of the chemical or physical investigator, whose exactness is proverbial. The mistake is to suppose that such technique is based solely on the teachings of anatomy. Such physiological facts as the reaction of the tissues to the trauma of operating, or the changes of digestion brought about by new anatomical relations, are of vast importance. The avoidance of the dangerous symptoms which sometimes follow the operation for exophthalmic goitre will never be achieved by anatomical studies, nor could it have been argued from structure that, in order to anastomose the intestine, peritoneal surfaces must be brought and maintained in apposition.

Such examples might be multiplied almost indefinitely, but sufficient has been said to show the paramount place which physiology plays in the problems of surgery. It is not surprising to learn that the greatest surgeons have nearly always been physiologists. VICTOR HORSLEY was a great example of this, and it is well to be reminded that LISTER himself made many physiological investigations. The association of the surgeon with the physiologist in many of our London hospitals is not as close as is desirable. Whilst the surgeon has everything to learn from the physiologist, there is no doubt that he can contribute hugely to the common store of knowledge and so make physiological experimentation conform more to the actual conditions present during life. For it must be admitted that many of the experiments of the physiologist are crude in their commencements, so that at first the deductions made from them require careful evaluation. The ideal in all physiological experiments is to disturb as few factors as possible and those affected should be known. Only in this way can we obtain unequivocal results. It seems that the realisation of this ideal would be made appreciably nearer by a closer association of the surgeon with the physiologist, and there are not wanting signs that this is being attempted.

PUBLIC HEALTH IN LOCAL LEGISLATION.

THE Special Report of the House of Commons Select Committee on Local Legislation in 1923 gives prominence once again to a matter to which once again we draw attention. "Most of the Bills which your Committee have considered during this, as in previous sessions, contained provisions relating to public health, sanitation, and other matters which were set out in the Special Report of 1922. Your Committee would emphasise what they have pointed out in previous years, that, as many of these powers are now usually sought, a consolidation and extension of the Public Health Acts, 1875–1907, so as to include such powers under general legislation, would be extremely beneficial to local authorities." Owing to the inexplicable delay in printing the Local Acts,[1] comment on their general contents must be suspended till the text is available. Even the Special Report from which we have quoted, though ordered by the House to be printed as long ago as July 31st, has only now appeared. The Report, however, mentions an interesting clause in the Chesterfield Corporation Bill which empowers the local authority to prohibit squatters or gipsies who prove themselves a nuisance or injurious to health from settling within certain limits. The Report also comments on the measures for tuberculosis prevention authorised in the Torquay Corporation Bill. "Your Committee, bearing in mind the peculiar position of Torquay as a health resort, considered it necessary that any person having the charge, management, or control of any hotel, boarding-house, or lodging-house should compulsorily notify such cases to the proper person." There is no occasion for apologetics or for special treatment. Let all honour be paid to Torquay for its progressive attitude, but in the fight against disease there is no monopoly of the best weapons; what is good enough for Torquay is good enough for the rest of the country. Similarly the Maidstone Corporation Act (which received the Royal Assent on July 18th, but has only now appeared in print) exhibits all those public health provisions with which a modern borough seeks to equip itself—the measures for drainage and sewerage (including power to repair private drains), for properly ventilated larders in dwelling-houses, for an adequate system of domestic sanitation, for preventing the spread in Sunday schools of "infectious disease" (defined to include measles, German measles, whooping-cough, chicken-pox, and influenza), for the medical inspection of inmates of common lodging-houses in times of epidemic, for the removal of infectious corpses, for taking to hospital sufferers from pulmonary tuberculosis, for tracing infected clothes to laundries, for regulating ice-cream manufacturers, retailers of milk, and rag-and-bone merchants, for cleansing verminous houses, persons and children, and for the protection of meat-supply. Why should a progressive municipality be put to all the trouble and expense of obtaining these powers or of securing local improvements upon the general Public Health Acts when Parliament might confer these benefits upon the country as a whole?

---

[1] See THE LANCET, Oct. 6th, p. 796.

Apart from the question of extending and amending the Public Health Acts the need of consolidating them remains as urgent as ever. The original measure is obsolete in its references both to the central and the local authorities entrusted with health administration, and everyone concerned is handicapped by having to work with a series of amending and overlapping enactments. On the second reading of the National Health Insurance (Consolidation) Bill, Lord ONSLOW indicated that it was hoped to consolidate also the law of housing and of public health. In the latter case particularly the process has long been overdue.

Annotations.

"Ne quid nimis."

HARVEIAN CELEBRATIONS AT THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

ON Thursday, Oct. 18th, being St. Luke's Day, after the delivery of the Harveian Oration, which we published in our issue of Oct. 20th, the Royal College of Physicians of London held the usual Commemoration Dinner. Sir Humphry Rolleston, the President, presided over a large assembly of officers and Fellows of the College and their guests, who included the Minister of Health, the President of the Royal College of Physicians of Edinburgh, the President of the Royal College of Surgeons of England, the Medical Director-General of the Navy, Air-Commodore Munro, Lord Justice Atkin, Lord Chelmsford, Dr. R. W. Innes Smith, Prof. Langley, and Sir Squire Sprigge. The health of Prof. Starling, the Hunterian orator of the year, was proposed in happy terms by Dr. John Fawcett, the Senior Censor of the College, whose recognition of the great physiologist as being *in esse* and *posse* a great physician was received enthusiastically by an audience which knew the long and distinguished tale of Prof. Starling's medical war history. The closing section of the Harveian address was an exact illustration of the way in which the highest and most elaborate physiological researches can be brought to play their part in practical therapeutics. Prof. Starling, in reply to the toast, brought out the interesting fact that the choice of a physiologist to deliver the Harveian oration, which is the greatest distinction that a Fellow of the College can be asked to enjoy, had one particularly interesting precedent, for the last time that the oration was delivered by a Fellow of the College, not holding a clinical position, was when the Harveian orator, in 1873, was Prof. George Rolleston, Professor of Anatomy and Physiology in the University of Oxford, and father of the President of the College to-day. Sir Humphry Rolleston, in proposing the health of the guests, to which the Minister of Health and Lord Chelmsford replied, alluded to the award of the Baly medal to Mr. Joseph Barcroft, the Bisset-Hawkins medal to Dr. T. M. Legge, and the generosity of Dr. R. W. Innes Smith in presenting to the College a portrait of Sir Charles Scarburgh, which he had traced from the Temple Newsam Collection, lately dispersed.

STRICTURE OF THE ŒSOPHAGUS FOLLOWING TYPHOID FEVER.

Dr. P. P. Vinson,[1] of the Mayo Foundation for Medical Education and Research of the Minnesota University Graduate School, remarks that ulceration in the œsophagus is one of the rare manifestations of typhoid. In 2000 autopsies on typhoid cases reported by Hölscher the condition was found only once. On the other hand, Louis found œsophageal ulceration in 7 out of 46 typhoid autopsies, and Mitchell in 1 out of 56. In 1904 Thompson recorded three personal cases of œsophageal stricture following typhoid, and collected nine others from the literature. Turner had another in 1902, since when Dr. Vinson has been unable to find a report of any further case. He now records 13 cases of stricture of the œsophagus following typhoid in patients aged from 13 to 47, which have been observed at the Mayo Clinic since 1909. Of the total 26 cases only 13 occurred in women. The stricture was usually situated in the lower part of the œsophagus, corresponding to the commonest site of ulceration. Of the 13 cases previously recorded, three died from lack of treatment, one died during treatment, and three had gastrostomy performed. The remaining six were apparently cured by the passage of sounds, seven of the Mayo Clinic series had had gastrostomy performed elsewhere, and in four of these the stricture was impermeable. In six of the patients without and in two with gastrostomy normal deglutition was restored by dilatation with graduated sounds.

THE BLOOD PRESSURE IN SCARLET FEVER.

Dr. R. Doria,[2] of the isolation department of the Umberto I. Policlinic, Rome, reviews the literature, including the papers of Teissier and Tanon (1908), Nobécourt and Tixier (1908), and J. D. Rolleston (1912), and records his own observations on 67 patients aged from 16 months to 32 years; 32 were males and 35 females. The maximum and minimum pressures were examined by the auscultatory method with Riva-Rocci's instrument. The measurements were generally taken at the same hour, usually in the early afternoon, and in some instances in the morning. No differences were observed between males and females of the same age as regards either the maximum or minimum pressure. Dr. Doria's conclusions were as follows: (1) Scarlet fever causes a fall of blood pressure like almost all the acute infectious diseases, with the exception of malaria. (2) This fall of blood pressure takes place more or less early, and may appear in the pre-eruptive, eruptive, or desquamation stage. It is more or less persistent, lasting usually a week at least. Its intensity varies, being most pronounced in severe cases, of which there were 14 in the present series, while in others it is slight or barely perceptible. (3) The fall of blood pressure is obviously connected with the general vaso-dilatation and weakness of the left ventricle in scarlet fever. It is not necessarily due, even when it is pronounced, to severe organic lesions of the suprarenals. (4) There is usually a more or less marked diastolic hypertension, the diastolic pressure showing a tendency to increase throughout the disease. Sometimes in convalescence there is for a short period a fall in diastolic pressure, which should serve as a warning of a sudden attack of cardiac insufficiency. (5) Accidental rises of the maximum pressure have no special prognostic value, and are often due to painful complications. A rise of the maximum pressure to the normal level in association with albuminuria should make one fear the onset of nephritis, whereas albuminuria without a rise of blood pressure does not, as a rule, precede nephritis. (6) Injections of convalescent and anti-streptococcic serum, the serum disease, and injections of vaccine cause a more or less considerable fall of blood pressure. Apart from these cases a sudden fall of the diastolic pressure, especially if it is associated with a diminution of the diastolic pressure, indicates the onset of a complication, particularly one affecting the heart. (7) The hypotension of scarlet fever cannot be attributed to the diet, because it is found in patients who are taking an adequate supply of nourishment, and sometimes appears at a very early stage, nor can it be explained by the patients lying in bed as it often persists after they have got up.

BILHARZIASIS IN THE DONGOLA PROVINCE OF THE SUDAN.

THE Dongola Province is one of the most fertile agricultural areas of northern Sudan, producing crops of millet, wheat, and cotton. Irrigation was formerly performed by the historic Sakia, but this is now being superseded by a series of pumping stations installed by the Government. It appears that bilharziasis has recently appeared in the Province, the infection having been introduced by the Egyptian labourers engaged on the irrigation works. The urinary form of infection caused by *Schistosoma hæmatobium* prevails and suitable intermediaries in the shape of fresh-water molluscs known as *Isodora innesi*, originally determined by Leiper as a possible host, abound in the irrigation canal. The susceptibility of this particular variety of snail to infection not having been experimentally determined, R. G. Archibald attempted to infect a number of them artificially with miracidia obtained from a local case of bladder bilharziasis and has succeeded in doing so. He has recorded his experiments in the Transactions of the Royal Society of Tropical Medicine (xvi., 7, 419). It was soon ascertained that this species is very susceptible, but owing to the high mortality-rate in captivity, it was impossible to state what was the actual proportion of snails infected. The characters of the cercariæ derived from these artificially infected snails agreed on the whole with those already published, and measurements taken from 30 specimens also agreed closely with those of Manson-Bahr,[1] Fairley, and Faust.[2] With the active cercariæ derived from an infected mollusc Archibald succeeded in infecting a monkey which was killed in the seventh week. A number of adult schistosomes with the morphological characters of *S. hæmatobium* were found in the portal vein. Armed with this knowledge, the following measures are suggested for the eradication of the disease in the Dongola Province: (1) The cure of cases of the disease by means of antimony therapy should be undertaken. This, even under the most ideal conditions, can be only partially successful, since large numbers of infected natives cannot be induced to undergo the treatment; nor is it possible adequately to check the results by laboratory investigation. There are always large numbers of latent cases with either very slight or non-existent symptoms which escape detection. (2) Measures undertaken with the idea of destroying the intermediary host appear to be more hopeful. This particular snail dies if deprived of water for a period longer than six hours. An intermittent system of irrigation would give the canals time to become dry and in this period the snails would die off, but this must be combined with measures undertaken to clear out the ponds and collections of water which occur in the neighbourhood of the sluices. This should be done at periodic intervals and the natives should be encouraged to keep domestic ducks which feed on these snails. Wiring of the intake pipes as a means of preventing the ingress of molluscs on floating weeds is suggested as a subsidiary measure. Other suggestions are the supply of well water to the natives for ablution and drinking purposes, and the initiation of propaganda measures in the form of illustrated pamphlets printed in Arabic, calling attention to the danger of drinking water from the irrigation canals, and illustrating the part played by the mollusc in the spread of the disease.

SCIENTIFIC INSTRUMENTS.

IN the first number of the *Journal of Scientific Instruments* the chief item of medical interest is that on a new Recording Kata-Thermometer, by Dr. E. H. Schuster. The original instrument by Dr. Leonard Hill was designed to measure the power of the air to cool the human body. The actual observations necessitated temperature readings and the time required for certain temperature changes. In the new apparatus described this is carried out automatically, and a tracing is made consisting of a horizontal line broken every quarter of an hour to give a record of elapsed time, and above this a series of vertical ordinates to represent the number of seconds taken by the instrument to cool through the specified range. This appears to be a useful modification of the original design, and it is likely to be of great industrial service to have an instrument which automatically records a very important factor in the hygiene of the workshop. It is gratifying to see in the production of this journal that the joint efforts of the Institute of Physics and the National Physical Laboratory have borne good fruit. Provided it gets the necessary support from investigators and inventors it is certain to find a place in the ever-increasing periodical literature of the scientific man. The contents of this first issue are extraordinarily varied, the contributions being from applied mathematicians, electrical experts, chemists, inventors; there is included a brief but very practical article on the Chain Balance, by Sir Flinders Petrie.

THE BOARD OF CONTROL FOR SCOTLAND.

THE Ninth Annual Report of the General Board of Control for Scotland records an increase in the total number of insane of 229, and a considerable increase in expenditure. Every district had sufficient accommodation for its insane except Glasgow, some of whose patients are placed in more or less remote asylums, and can therefore not easily be visited by their relatives. The reopening of the Edinburgh District Asylum, following its evacuation by the military authorities, has been accompanied by various structural improvements, and entailed the transference of 600 patients. Statistics apart, the bulk of the Report is composed of abstracts from the Medical Commissioners' reports on each institution, including the lunatic wards of poor-houses. The impression created by these reports is one of excellent management and general efficiency. Such criticisms as are made, which apply in some cases to only one or a few institutions, concern the lack of facilities for proper classification of patients, and in particular for isolating recent cases, the imperfect isolation of the tuberculous, and the neglect of post-mortem examinations. There is a remarkable absence of any adverse criticism of food or clothing.

A feature of the Board's work which evidently causes some anxiety concerns the disposal of the mentally defective. The imperial grant for this purpose covers the maintenance in institutions of only 1477 defectives, and an additional grant recently made only partly covers the expenses of 200 more. Three districts have therefore undertaken the institutional treatment of numbers of defectives at their own expense. The respective merits of home, institutional, and boarding-out treatment at various ages are discussed at some length. The absence of accommodation for ordinary defectives over 16 years of age has led to the practice of defectives being retained in their own homes where these are considered suitable, or where the parent is unwilling or refuses to part with them, or they are placed under guardianship. Many of these defectives are of an age when special care and institutional training, particularly in the form of industrial and farm colonies, are required to complete and consolidate the education and training gained in special schools and classes and in defective institutions. Hitherto, if they cannot be kept at home, or if the home conditions are unfavourable, or their mental conditions are such as to demand institutional care, these defectives have been certified under the Lunacy Acts and placed in asylums. The Board do not view this practice with favour.

ACTIVE AND PASSIVE IMMUNISATION IN TUBERCULOSIS.

IN a communication to the *Deutsche medizinische Wochenschrift*, published on Sept. 21st, Prof. Paul Uhlenhuth has given an account of laborious investigations carried out by himself and his colleagues during the past few years. They have attempted in various ways to immunise experimental animals to tuberculosis by the injection of the products of tubercle bacilli treated in an almost infinite variety of ways. The most effective means of robbing the tubercle bacillus of its waxy and fatty capsule proved to be treatment of tubercle bacilli for two days with chemically pure trichlorethylene at room temperature, or at 37° C. But whether the various constituents of the tubercle bacillus were injected singly or together, the fate of the rabbits and the guinea-pigs was the same; they fared no better than the control animals when inoculated with virulent tubercle bacilli. No better results were obtained with the injection of tubercle bacilli which had been exposed to circulating steam for two hours, or to a dry heat of 150° C. for half an hour. Other experiments were also carried out with tubercle bacilli treated with antiformin and then washed with saline solution, dried, and pulverised. The injection of an emulsion of this pulverised tubercle powder into rabbits and guinea-pigs failed to avert death from tuberculosis when these animals were inoculated with virulent tubercle bacilli, and Prof. Uhlenhuth confesses that he is very pessimistic as to the likelihood of immunity to tuberculosis being achieved by the administration of dead products of the tubercle bacillus. Another line of research on which he has been engaged has been to inoculate cattle with a 21-year old avirulent strain of tubercle bacilli, and to inject the serum obtained from these cattle into guinea-pigs. The response of the guinea-pigs thus treated has been quite disappointing; their reaction to a subsequent inoculation with virulent tubercle bacilli has not been appreciably better than that of the control animals. So far Prof. Uhlenhuth's account is a long record of uninterrupted ill successes. But at the end of his paper he refers to some hopeful clinical investigations made by his colleague, Prof. Czerny, who has given to tuberculous children the serum obtained from cattle inoculated with large doses of avirulent bacilli. Prof. Czerny's account is to be published in the forthcoming number of *Jahrbuch für Kinderheilkunde*. Prof. Uhlenhuth is, however, able to state that the results obtained by Prof. Czerny in 20 cases of severe tuberculosis of the lungs, larynx, and other organs were remarkably good, the response being considerably better than in the control cases given ordinary bovine serum, or the serum of previously untreated horses and asses. Prof. Uhlenhuth hopes that extensive clinical research will be carried out on the lines indicated, and that with the judicious use of controls it should be possible to form a fair opinion of the merits of this form of serum treatment in tuberculosis.

A CURIOUS CONDITION OF THE SEMILUNAR CARPAL BONE.

A PECULIAR condition of the semilunar carpal bone, resembling osteo-malacia, is described by Prof. Dr. Sonntag.[1] In his opinion it occurs more frequently than the few reports would lead one to think. The disease can be compared to the condition found in the head of the femur in Perthes's disease, and to that of Köhler's disease of the head of the second metatarsal bone. The condition was first described by Kienbock in 1910, and since then reports have been published by Preiser, Guye, Frenkel-Tissot, Müller and Sonntag, numbering some 30 cases in all. Prof. Sonntag now reports 12 cases occurring in the chirurgische Poliklinik in the University of Leipzig during the last year, and from this it appears that the disease must be of not very infrequent occurrence, were it only recognised. It is found in both sexes, between the ages of 17 and 45, rather more often in the right hand than the left, and chiefly among manual workers. In a few of the cases the semilunar bone has been removed by operation, when the following pathological changes have been found. Macroscopically the bone appears to be irregularly compressed proximo-distally, and sometimes it is found in several pieces, more or less adhering together, so that the pieces are removed separately at operation. The proximal joint surface shows the greatest changes; it is yellowish in colour and irregularly scarred, in parts either eroded or destroyed or split, and sometimes crumpled as though it were disturbed by the underlying collapse of bone. One case had a piece of cartilage raised up and projecting into the joint cavity, the defect being filled with granulation tissue. The overlying ligaments are often much hardened with callus, while the neighbouring bones show deformatory changes. Microscopically the proximal part of the bone shows necrosis of the spongiosum, with new formation and destruction of bone tissue, osteoid tissue surrounding the laminæ, deposition of calcium, connective tissue formation, and cellular infiltration in the neighbourhood of the necrotic foci. There is never any evidence of tuberculous or syphilitic infection. The changes resemble rather incomplete healing of a fracture, but the condition cannot be explained on this basis owing to the fact that half the cases occur in the absence of any recognisable trauma. In those cases in which a trauma has been present X ray examination shows no changes in the early stages, but only some months later reveals the characteristic changes, thus suggesting that the fractures are secondary, and occur as a result of the previous necrosis of bone. The latter may be due possibly to some interference with the blood supply, which may in some cases be consequent to slight trauma causing the condition generally diagnosed as contusion or sprain. These cases might be called post-traumatic. In the group in which no trauma is recognised the condition may possibly be caused by repeated small occupational injury.

Constitutional changes, such as late rickets, can be excluded, as the general condition of the patient is usually very good. Clinically three stages may be recognised: (1) symptoms of joint irritation (lasting a few days or weeks); (2) a comparatively symptomless stage (lasting a few weeks or months); and (3) the stage when the condition is well marked as a clinical entity, with an acute onset followed by permanent pain of moderate severity. In the non-traumatic variety the trouble develops after one or more acute attacks (which are, however, less acute than in the traumatic variety), until a chronic stage is reached. The clinical picture in an acute attack, which is usually brought on by some extra work or overstrain, and brings the patient to the doctor, is as follows: (*a*) pain with active and passive movements, especially on performing hard work; (*b*) localised pain over the semilunar on the dorsal and palmar aspects, mostly on hyperextension, but also on hyperflexion, and on pulling the hand or jarring it longitudinally; (*c*) swelling of the soft parts, mostly on the dorsal spect; (*d*) limitation of movements in all directions; (*e*) sometimes crepitation; (*f*) sometimes shortening of the whole wrist joint. Together with these symptoms there is loss of power in the hand, and sometimes muscular atrophy. The X ray picture in the early stages may be normal; later the characteristic changes consist in alteration of the structure, showing disturbance of the laminæ, with areas of density and opacity, arranged in patches or in stripes. The whole bone is compressed proximo-distally, like an impacted fracture. The proximal surface is irregular and less rounded, and often shows projecting particles. The bone may be divided into two or more pieces, or one corner may be cut off by a cleft. The other bones may be displaced. The diagnosis of a typical case can usually be made without difficulty on the clinical appearances once these are recognised, but in the early stages the condition cannot be distinguished from a contusion, and usually is diagnosed as such unless an X ray is taken at a later date. In Prof. Sonntag's series, after the first few cases were recognised, the remainder were diagnosed clinically in the out-patient department by the assistants and students. The condition can be diagnosed from fractures, dislocations, tuberculous affections, and osteo-arthritis by the X ray. Contusion and distortion give similar pictures, but can be distinguished by the fact that in the semilunar disease the disability continues much longer and tenderness is limited to the semilunar. The prognosis cannot be definitely stated without further and longer observations on more cases, but it can be said from the present experience that the prognosis respecting cure and function is very doubtful. The condition is usually chronic, and often leads to true osteo-arthritic changes. It is also not known how many slight cases cure themselves, but when once X ray changes are demonstrable it is likely that the disability will persist for years, if not for ever. Treatment is still uncertain. Conservative measures appear to give the best results; in the early cases treatment as for contusion; in the late as for osteo-arthritis. Operative removal of the bone has been carried out, but so far has not been uniformly satisfactory in relieving the symptoms.

ETCHER AND SURGEON.

THE etchings of Sir Francis Seymour Haden have recently been reproduced and published in one volume, under the editorship of Malcolm C. Salaman, a collection which should have a special interest for members of the medical profession. It is but seldom that distinguished service to the science of medicine is combined with outstanding work in any field of art, yet in the late Sir Francis Seymour Haden there were united a surgeon and an artist of renown. During his medical student days, part of which were spent in Paris, Haden devoted much of his spare time to study in the art schools, less from any artistic inclination than with the object of training hand and eye for surgical work. In after years he laid stress on the importance of such a training for medicine, saying, "How much sooner would the eye accustomed to observe and estimate closely differences of colour, aspect, weight, and symmetry, learn to gauge their aberrations as the signs which make up the *facies* of disease; how much better the hand, trained to pourtray them accurately, be able to direct with precision and safety the course of the knife?" Among his fellow practitioners Haden was noted for an instinctive power of diagnosis, which was attributed often to his disciplined sense of vision. Haden continued his practice as a surgeon until 1887. He pursued the art and study of etching mainly as a relaxation from his professional work, but it is his etchings which form the chief memorial of his life. He first exhibited in the Royal Academy in 1860 under the pseudonym of "H. Dean," but in 1864 he signed his work in his own name. In 1880 he founded the Society (now the Royal Society) of Painter-Etchers, whose president he remained till his death in 1910. In 1905 his distinction was recognised abroad by honorary membership of the Institut de France, the Académie des Beaux Arts, and the Société des Artistes Français. He gained the Grands Prix at the Expositions Universelles at Paris in 1880 and 1900. Though at first treating art as a handmaiden of medicine, Haden became, not merely a doctor with an interest in the beaux arts, but a great artist. He shared with Whistler, his brother-in-law, the claim to being one of the finest etchers of his day, and it is mainly to his work and enthusiasm that the revival of etching in this country is due. It is interesting to note that some of Haden's early drawings appeared in the pages of THE LANCET. In 1862 a report on surgical instruments shown at the International Exhibition of that year was given in our columns, illustrated by accurate drawings. Many of these engravings were from Haden's burin, and though they could hardly claim, on grounds of the subject, inclusion in a collection of his artistic studies, nevertheless they possess value as showing one manner in which Haden employed his skill to medical ends.

PREGNANCY AND TUBERCULOSIS.

FOR almost a generation our attitude towards the combination of pregnancy with pulmonary tuberculosis has largely been determined by the aphorism, credited by Osler to Dubois, that the woman threatened with pulmonary tuberculosis may bear the first accouchement well, the second with difficulty, the third, never. With rather halting logic, this aphorism has often been the excuse for the induction of abortion. The revolt against this course was started a few years ago by Prof. Forssner, of Stockholm, and of late his plea in favour of conservative treatment has found much support. Two of the most recent publications on this subject may briefly be referred to. In the annual report of the chief tuberculosis officer for Belfast for the year ending Dec. 31st, 1922, there is an instructive analysis of the result of pregnancy in 1375 tuberculous women. It was found that tuberculosis was not a very active cause of premature birth, and that among the 6·3 per cent. of the patients who miscarried, other causes than tuberculosis may have been at work. With regard to the effect of pregnancy on the clinical course of tuberculosis, it was found that, unless the disease was in an acute or advanced stage, the normal course of pregnancy was not disturbed. The second publication referred to is a paper by Dr. A. Scherer,[1] of Magdeburg. His analysis of 8520 definite cases of pulmonary tuberculosis in women of the child-bearing age showed that in only a small fraction could pregnancy be convicted of playing a sinister part in the propagation of the disease. In 103 cases the interruption of pregnancy had been advised, but only in 72 cases had this advice been followed. The remaining 31 women objected, partly on religious grounds, to this procedure, and they served as controls to the 72 cases in which the experiment of interrupting pregnancy was carried into effect. Only in 19 of these 72 cases did sacrificing the child prove beneficial or at least harmless. As for the 31 women who refused interference, as many as 22 not only went to term, but gave birth to living children, and when the mothers were examined some time later, they were still in comparatively good health. The lesson of Dr. Scherer's investigations is that pregnancy which occurs frequently at short intervals may, indeed, be injurious as far as tuberculosis is concerned.

---

[1] Beitr. z. Klin. d. Tuberk., 1923, lxvi., 234.

but that interrupting pregnancy is a remedy of very doubtful value. Another German authority, Dr. Schellenberg, has published in the same journal statistics supporting the views of Dr. Scherer, and in Germany as well as in France the movement would seem to be gaining ground which favours the careful supervision of pregnant women in a sanatorium or other institution during and immediately after pregnancy.

A PROPOSAL FOR DEVOLUTION.

THE rapid development of our knowledge in preventive medicine has had and is having a profound effect on the administrative side of the public health service, as Sir George Newman has pointed out on many occasions. For example, the reduction of enteric fever can be attributed to improvement in water-supply, drainage, sewerage, and refuse disposal, and the control of food, including shell-fish. Still undefeated enemies from the preventive standpoint are respiratory diseases, heart and circulatory troubles, nervous diseases, and cancer. These must necessarily be attacked mainly from the personal aspects, and it is these aspects which have been raised by Lieut.-Colonel F. E. Fremantle, M.P., in a letter to the Prime Minister published recently. Colonel Fremantle thinks that the time has come for a reconsideration of health administration, which will lead to the crystallisation of the views of many people. He makes concrete proposals for changes in central administration which are revolutionary in character, being no less than the abolition of the Ministry of Health and the transfer of its powers to the Office of Works as to housing, Home Office as to local government (presumably including Poor-law work), and the Board of Education as to its health functions. Colonel Fremantle's suggestion, broadly speaking, is that with the development of our knowledge sanitary works of the character of water-supply and sewerage have no longer the importance which they had in the past, and that future progress is to be found in "research (under the Privy Council) and public enlightenment, which surely should come under the Board of Education." In considering his proposals some guidance can be gathered from the lost opportunities of the past. In 1871 Sir John Simon pointed out that the opportunity of placing a new branch of work—sanitary administration—on a sound basis was spoilt by grafting it on to an existing department which was bound to be to its detriment, and it has been abundantly shown that the association of health work with Poor-law administration was a mistake. Colonel Fremantle refers to the need of intelligent use of the human factor in every department of local or national government, as well as in what, because of former deficiencies, have been looked on as works of sanitation—water-supply, sewerage—or housing or hospitals. His use of the word "former" suggests that there is no need for further activity in these matters. Happy would be the area of which this could be said, but even if it were true of the large towns, there is much to be done in the vast tracts of county areas before even modest ambitions with respect to water-supply, sewerage, refuse disposal, and isolation hospitals would be satisfied. These are hardly cognate to the work of the Board of Education. We agree with Colonel Fremantle—that knowledge of prevention of illness and disease has reached the stage when public enlightenment is an even more important factor than it has been at any previous time, and for this the community requires a central department which has preventive measures as its chief function. But the Ministry of Health has since its inception behaved as though prevention were its prime object, and though the Ministry might well be relieved of certain extraneous duties it must remain the central department for all health matters. Decentralisation of some of the functions of the Ministry can only be recommended with stringent safeguards for efficiency and economy.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XLII.—THE TREATMENT OF THE NEUROTIC.

SOME 40 articles have appeared in this series so far, each and all—with one exception, and that only apparent—dealing either with a definite type of disease or a definite objective symptom. The more impersonal and objective the condition, the simpler is its therapeutic consideration; specific ailments evoke specific treatment. Nothing could be more objective than club-foot, nothing more impersonal than scabies or pediculosis. By comparison, the physician called on to discuss the treatment of the neurotic and neurasthenic is doubly handicapped; he is not sure whether he is dealing with "disease" in the accepted sense of the word, and as a clinician he is frequently in justifiable doubt as to the reality of the symptoms he may be invited to dispel. He labours, however, under no misapprehension as to the commonness of nervous symptoms called neurotic or neurasthenic; were he prone to minimise their significance or ignore their universality, the rush of patients to the latest purveyor of mysterious panaceas, duly chronicled in the daily press, would remind him of his error. Whatever else is the matter is uncertain, this is clear, that there exists an immense amount of nervous ailment, real, exaggerated, or feigned, with which the practitioner of medicine should be able to cope, and for the continuance of which he cannot escape a modicum of responsibility.

It is unnecessary to indicate with greater particularity the nervous symptoms included under neurosis and neurasthenia, and it would be endless were it necessary. There is no kind or degree of ache or pain, of numbness or other paræsthesia, of fear or depression, of fatigue or ennui, of sensitiveness or apathy, of anxiety or moodiness, which cannot be set down to "the nerves" and for which relief will not be sought. No pretence is here made to define the landmarks or to specify their relative importance; no description can be given that will be universally applicable; but the physician in practice soon learns to separate the organic cases from the "functional," though here, as will be indicated later, lies a source of therapeutic trouble.

The Element of Fear.

For the successful treatment of the neurotic it is incumbent on the practitioner to realise in every instance that *there may exist in the patient's mind an element of fear or apprehension.* He has not the knowledge that the practitioner has; he is incapable of interpreting aright the symptoms that have begun to obtrude themselves into conscious notice; uneasy and concerned, a prey to too facile an imagination, especially if he is, as almost all of this class are, constitutionally sensitive, he seeks advice because he is dominated to some extent by foreboding. He may be afraid of having to relinquish his work, of having brought the trouble on by previous indiscretions, of failure on the part of the practitioner to diagnose his condition accurately, of insufficiency in respect of the treatment that will be suggested—in a word, he longs to be reassured about himself and his symptoms.

The physician's aim, therefore, must be to show by his investigation and his demeanour that he recognises the symptoms for what they are, that he is familiar with the course taken by such morbid conditions, and that he is confident a cure is practicable. He must never allow the patient to leave his room on the first visit without having taken definite steps to dispel apprehension. In this respect he might take a leaf out of the book of the "faith healer"; if he is true to his own intellect he cannot, like the latter, facilely deny the reality of disease, yet his optimistic outlook, and his willingness to take the burden of the patient's woes on his own shoulders, will serve as nothing else to relieve the patient's fears, and to inspire hope.

"*L'homme à Petits Papiers.*"

The successful practitioner, further, bears in mind the neurotic's *desire for a minute examination;* in his anxiety the latter commits a list of his chief symptoms to paper, lest any be forgotten at the consultation. Success in treatment depends equally on the physician's recognition of this fundamental trait in the neurotic mind. Studiously averting his eyes from the clock, the physician must "sit the neurasthenic out." No detail is too trivial to be mentioned, no form of examination otiose. It is a fatal mistake to hurry or harry the neurotic as he unfolds the story of his symptoms, and, as likely as not, his interpretation of them. The wise student of neurotic human nature is never hurried, never has to break off the consultation for a more important patient. *L'homme à petits papiers*, as Charcot dubbed him, has to be handled tactfully if he is to be treated successfully. It must not be supposed the assumption of a mere patronisingly tolerant attitude towards the nervous patient's longwindedness is here advocated; on the contrary, the obtaining of a detailed history must be supplemented by a thorough-going examination, on the physical side no less than on the mental. Such physical investigation is indispensable, for two reasons. In the first place, it impresses—never a negligible factor; and, secondly, it aids the practitioner to avoid the pitfall, already alluded to, of overlooking an organic element in a "functional" case. The neurotic patient loves to be examined; in view of his ready coöperation, why should the physician hesitate? It should be a routine procedure to "vet" the patient completely; each somatic system should be investigated. Many examples crowd into the mind of neurasthenic cases aggravated if not always caused by unsuspected sources of mischief in other systems than the nervous. In particular, the alimentary and urinary systems must be minutely scrutinised. Bacteriological examination is often a sine qua non. When the patient complains of being "out of sorts" and of vague nervous symptoms the search for a possible organic mischief-maker should be as thorough-going as the subjective complaint is slight. It is never wise to pooh-pooh a line of examination suggested by the patient himself. In the case, for example, of the neuropath who thinks there is something the matter with his heart and who has heard of newer methods of research the physician should be prepared to advise recourse to such technique. Similarly, the request for an X ray examination should never be refused. The mental satisfaction of knowing it proves "negative" is surely preferable to the doubt otherwise remaining, doubt which the patient's mental condition only serves to aggravate. The practitioner should play the part of the ferret; he should hunt over all the ground for any scent leading him to his quarry. He is clearly in better position to tackle his patient therapeutically when he has excluded early structural disease, or chronic infection, or glandular dysfunction.

The Value of Tangible Treatment.

The best results are obtained when *some kind of tangible treatment* is proposed and carried out. The doctor who "does something" has the pull over the other who says there is no disease, the symptoms are imaginary, and the condition will cure itself. A good deal of persistent slight nervous ill-health can be set right by physical exercises and baths. A bracing effect on the mind can be legitimately produced by purely physical methods. Sluggishness of somatic function may be responsible for "nerves," "the blues," headaches, depression, in many instances, and can be cured readily enough by appropriate means. One of my old teachers gave all his neurotic patients sulphur baths thrice weekly, knowing that the relish with which they looked forward to "bath day" during a Weir-Mitchell regime was worth much as a mental stimulant. The success of irregular practitioners or "cultists" of all sorts is largely due to their insistence on physical handling of the neuropath. If the end ever justifies the means it is in the realm of neurosis. Most doctors are naturally averse to anything even remotely suggesting humbug, and object to unscientific talk of vibrations, emanations, currents, and what not, but they need not be guilty either of charlatanism or of self-deception in adopting a sanguine attitude as to the efficacy of the mechano-therapeutic procedures they suggest for their cases. Massage and various forms of electrical treatment have always a place in the treatment of the neurotic and neurasthenic, and the most novel is not necessarily the best.

The Simpler Methods of Psychotherapy.

No less important must be attention to the patient's mind, and to his domestic and business situations. It has been well said that patients often need, not a physician, but a divorce, a child, a bank account, a job, a holiday, an aim in life, and the list can be extended materially by all who have to deal with the neurotic, whatever his social position. The error of prescribing a course of treatment which the sufferer is for domestic or financial or business reasons unable to carry out would never be committed were the whole circumstances of the patient discussed with the same care that may have been devoted to the medical aspect of his case. It should be axiomatic on the part of the physician to remember that the best treatment for the neurotic patient is not always the most strictly scientific. Occupational therapy, again, deserves mention in this respect. For many potentially neurotic people the multifarious activities developed by the war proved a perfect godsend, and the ennui of an aimless existence can be countered only by the obvious method of finding something for the patient to do. In the out-patient department not a few cases of neurosis have clearly been originated and intensified by the prevalent unemployment. Any persisting source of anxiety or worry engenders sleepless nights and starts a train of nervous symptoms which can only be dispelled by tackling the mischief at its origin. Hence the fundamental importance of ascertaining what is in the patient's mind. The attention which has been given in recent years to psycho-analysis has to some extent, at least, pushed into the background the simpler methods of psychotherapy at the disposal of every practitioner of medicine. The rational methods associated with the names of Dubois and of Dejerine will prove satisfactory enough in most ordinary cases. To take the patient understandingly over his case, interpreting his symptoms for him, pointing out in what respects he has exaggerated them or misunderstood their meaning, and imbuing him with a feeling of optimism and recoverability, will lead him far on the way to cure. It is a great thing for the constitutional neuropath to learn his own limitations and to order his life aright in view of these; nervous ill-health and nervous breakdowns can often thus be avoided.

THE PANEL CONFERENCE:

CAPITATION FEE AND APPROVED SOCIETY CONTROL.

THE annual conference of representatives of local medical and panel committees met at the Central Hall, Westminster, at 10 A.M., on Thursday, Oct. 18th, Dr. H. G. DAIN, Birmingham, presiding. The chairman broke his rule of not giving an opening address to point out that the situation was unique, for on every previous occasion the opportunity of arbitration was open to the Conference after reaching its decisions, whereas this time arbitration had been ruled out in advance by the Minister of Health. The Conference was dealing not merely with the capitation fee of the moment, but with the position of practitioners under the insurance scheme for years ahead. His hearers were the stewards of the traditions of the medical profession, and he put it to them —Are you still to be masters in your own house? Will you accept dictation on the terms of service from some outside body with no interest in medicine and no breadth of outlook? It was, he said, essential to reaffirm the position of 1912, when insurance doctors established their right to negotiate only with the Government. At the conclusion of his remarks the chairman undertook, in view of the likelihood of further conferences in the near future, to withdraw his previous determination not to stand again. The Conference then decided to take at once the latter half of the agenda dealing with remuneration.

REMUNERATION AND APPROVED SOCIETY CONTROL.

Dr. H. B. BRACKENBURY, chairman of the Insurance Acts Committee (hereinafter called I.A.C.) then delivered the following address:

Under the new conditions under which we meet there is a necessity for the revision of some of the recommendations set down on the agenda by the Insurance Acts Committee, and I propose, with your permission, to withdraw the motion which states that the offer of the Minister of 8*s.* 6*d.* for three years is inadequate and that arbitration upon the lines of that of 1920 be asked for, and to combine two of the other motions. [*The Conference agreed to this modification.*]

I now proceed to move—

That the Minister's offer of 8*s.* for five years or of 8*s.* 6*d.* for three years be definitely rejected.

I should like to emphasise the necessity of our considering this very important matter with great calmness. We desire not to work up any particular excitement about it, although a great determination; and we want everybody at this Conference to say what he feels and to point out to us our weak places so that if action is necessary action may properly be taken. Let us know exactly where we stand, what is best to be done, and quite clearly what our actual determination is. This resolution will, I hope, concentrate your attention on the immediate issue. There are all sorts of contingencies which may arise hereafter. It is quite conceivable that we may have to call a special conference, perhaps in the first week of November. But whatever conditions arise after Nov. 1st must be tackled then. I want to make an appeal to those who are here to-day to voice their difficulties and their views so that when the decision is come to we shall be prepared on matters of detail and tactics to sink our own individual views and stand together, and go on the lines which seem good to those who have shouldered the responsibility in this matter. (Applause.)

Four Alternatives.

When we come to the problem which is before us—namely, what are the terms and conditions of service upon which it is proper for the profession to serve the community in this matter?—we find that there are four ways in which that question may be settled. They can be summed up in four words: Submission, negotiation, arbitration, and conflict. The Insurance Acts Committee would have preferred the method of negotiation. So far there has been no negotiation on this matter at all. The Committee was requested to prepare a statement of our case. We prepared and presented it in document M.1. The Minister to that prepared an answer which was to be a final answer. He was approached—quite properly as I think—by the approved societies, as by any other body of persons interested in the matter, and asked to hear what they had to say before he gave his decision. He met them and heard them. Then it was pointed out to him that it was only fair that he should meet us also, and he met and heard us. But at that conference he told us that he had been immensely impressed by the things which had been said to him at his conference with representatives of approved societies, though he declined to tell us what the things were which had impressed him. Certain whispers had come to us as to what had happened, and we found that the things which did come to our notice, if they were what was actually said, were things which it was perfectly easy to answer and absolutely necessary to contradict. But so far as the Minister was concerned, we had no information as to what had passed at that conference, and what points the approved societies had brought forward; therefore we had no opportunity to deal with those statements. Again, he told us that the Ministry's answer to our document had been prepared—I do not mean that it was not subject to alteration—and that in his view it was a magnificent answer, one of the finest documents he had seen, but he deliberately and finally declined to tell us anything that was in it! The Committee was therefore presented with a final judgment on the matter without being afforded opportunity of any conversations with a view to agreement if that judgment were not accepted. That is not what I conceive to be negotiation. (Applause.) We are in this position: Negotiation has not been tried, and, as I shall tell you later, there is only one method left for us to take in order that negotiations may be, not reopened, but may begin. The Committee was prepared to negotiate, and indicated this to the Minister; and anyone, I should have thought, with a spark of statesmanship would have sent for the representatives of the insurance practitioners, at all events in an unofficial capacity, and asked if by putting our heads together we could not arrive at some solution. No such message came. We simply had another answer. telling us that the Minister had said—what he had said! You have that reply before you, and you have before you also the answer which was immediately sent to that, stating our position at the moment. The Insurance Acts Committee will, I am sure, forgive me for having sent that answer, after consultation with Dr. Cox and Dr. Anderson, but without opportunity for consultation with the Committee as a whole. ("Hear, hear.") But that is the position: Negotiations have not taken place; we have asked for them, we have waited for them, and no invitation has come to us.

Negotations not having taken place, and the opportunity for such not having been offered, we turned to the next course at once. This was arbitration. We said, "If negotiations are not going to take place the next thing we are going to ask for is arbitration." We proposed to ask this Conference to authorise us to ask for arbitration. Arbitration is refused. We are told we cannot have it, and as far as the Insurance Acts Committee is concerned we do not propose to press for it, although an expression of opinion from this Conference that arbitration in the circumstances was a possible and suitable method of dealing with the matter might perhaps not be amiss.

Economic Grounds of Refusal of Insurance Acts Committee to Accept Offer of Ministry of Health.

Negotiations being out of the question at the moment and arbitration being refused, we are left with the almost unbelievably simple issue, though the extremely serious issue, of submission or conflict. (Applause.) And the Insurance Acts Committee asks you to endorse its opinion, which it makes to you in the form of the recommendation I am proposing, that we will not accept the offers which have been made. (Loud applause.)

On three grounds we cannot accept these offers. In the first place, the offers are economically unjust. I do not take these points in the order of their importance, but in the order in which it is convenient for us to consider them at the moment. I am not going to labour this economic point. We set out our full case in document M.1 to the Ministry, and from beginning to end of the Minister's answers there has been no real attempt to meet the facts and the figures and the arguments and the conclusions which we reached in M.1. All sorts of other things have been taken and said, but there has been no attempt to contradict or show errors in the facts or calculations which we have submitted to him on the economic issue. I will put it to you in one way which has not been over-emphasised. We will take the figure of 7*s.* 3*d.*, which was our capitation fee in pre-war—indeed up to mid-war—times. It has been generally agreed between us and the Ministry that 25 per cent. of the remuneration might well be regarded on the average as payment for practice expenses. That would take 1*s.* 10*d.* off the 7*s.* 3*d.*, and leave us with 5*s.* 5*d.* as our former net remuneration expressed in terms of the capitation fee. Our practice expenses to-day may definitely and properly be taken to be 50 per cent. in excess of what they were in 1913–14. If we take 1*s.* 10*d.* plus 50 per cent. and deduct this from the proposed capitation fee of 8*s.* 6*s.* we arrive at a capitation fee of 5*s.* 9*d.* Expressed, therefore, in net terms, we are offered to-day a capitation fee of 5*s.* 9*d.* as against a capitation fee of 5*s.* 5*d.* in the earlier days; an increase of 6 per cent., as against an increase of expenditure which has to be met out of this net remuneration of 57 per cent. according to Prof. Bowley, or of 75 per cent. according to the official figures which are issued month by month. Our contention that it was by no means certain that this index figure representing the cost of living was going to be a continuously falling figure is borne out by the fact that in each of the two months since we made that prophecy that index figure has gone up, and it is to-day 175 as against 169, at which it stood when we made the proposition. We are faced, therefore, with an offer which on purely economic grounds would raise our spending amount by 6 per cent. as against a reduced spending power of 57 per cent. or of 75 per cent. as the case may be; and that is in addition to and apart from the reduction in the standard of living which is imposed upon us all by the enormously increased taxation. We say, therefore, that on the economic side alone such an offer is unjust, and it is important for us individually that we should have such a remuneration as will make it possible for us to live in the way in which we ought to be able to live and to bring up our children so educated that they will be able to take a position in life not less than that which we have been able to take ourselves.

Necessity for Good Standing of Panel Practice in the Medical Profession.

But, after all, there may have been considerations which would bring home to some men's minds a doubt as to whether they should or should not accept the figure of 8*s.* 6*d.* What I say to you this morning is that the economic argument, while we do not minimise it in the least, must now have a subordinate place. There are other things which make us feel we have no option but to reject this offer. In the first place, we believe that the position which has been opened up before us in these proposals is nationally unsound and socially dangerous. Some of us believe whole-heartedly that a national health system, founded upon an insurance basis, is a good policy for the nation; but obviously if there is to be a national policy in that direction and on those lines it must be such a policy as will enable the whole medical profession heartily and willingly to coöperate in it, and not such a method as will give to the industrial population, whether in town or country, the services of doctors relatively inexperienced or driven to accept what they do accept by sheer economic need, and will make those who have been more successful endeavour to get out of the service at the earliest possible moment. It would be a disaster to allow a national system, paid for nationally and arranged nationally, to go on, which only left in the industrial areas of this country those doctors who are forced to go there, instead of leaving in those areas (as in other places) a considerable number of willing practitioners who will serve as well and as satisfactorily, and with as great a care for individual and social welfare, in those areas as in other communities more fortunately situated. (Applause.) To accept an offer of the present kind would result in that unfortunate state of affairs. (Applause.)

Who Represents the Real Interests of Insured Persons?

The third reason why we are unable to accept this offer, in the opinion of the Insurance Acts Committee, is because the circumstances in which the offer is made necessitate the protest of an honourable and independent profession. (Loud applause.) There was a conference of representatives of approved societies yesterday, and at that conference a very wise speech was made by Mr. J. H. Thomas, M.P.—a wise speech, I mean, considering the point of view from which he had to speak, and the audience to which he had to address his remarks. If we had to deal with people such as Mr. Thomas I have no doubt we should be able to arrive at a peaceful solution. But there is this fundamental point which is a fallacy in Mr. Thomas's speech—he said that the conference he was addressing was in a position to speak for every section and class of insured persons. Mr. Thomas appealed to the doctors not to disgrace the great heritage of their profession and engage in a conflict with 16 million people less fortunate than themselves. (Laughter.) Our conflict is not with those people, but on their behalf. Of course, it is the rôle of approved society officials to represent themselves to Ministers and to impress upon Ministers and upon the public that they represent the 16 million insured persons. But we know here that the attitude of the enormous mass of insured persons towards approved societies and their officials, where it is not one of indifference, is one of antagonism. (Applause.) The insured persons have been compelled to join the societies in order that they may reap the full benefits of the premiums they are compelled to pay, but in coming to us to help them we find that it is very common for them to regard their approved society as a remote entity and the society official as a person continually trying to do them out of their just rights. ("Hear, hear.") It is to us they come when they want help, and we can tell the Minister and the approved societies that so far as real knowledge of insured persons is concerned and real help given to insured persons in connexion with the problems of national insurance which they, very naturally, incompletely understand, it is to the doctor they come most of all, and, I rather suspect, next to the doctor, the clerk of the insurance committee. They do not get the help they might get from the officials of approved societies. But the societies, having adopted that rôle, now assume to themselves the position of being the community. They have in so many words, through their spokesman—there must be some of them who do not like it—claimed that the Minister has no "right" to alter the terms and conditions of service, that he has no "authority" to negotiate about a capitation fee without their permission, and that they and they alone are the persons who can properly say what are the conditions of service and the terms. There is no ambiguity about it. The statements of their claims which I have just made are quotations from speeches made by those who speak on behalf of the approved societies.

Then, Sir, we say that from the beginning the approved societies have taken the narrowest and lowest commercial view of the medical profession, and that they claim in effect to get into the position of being the employers, the masters, the paymasters of the profession. That is a position which we fought in 1911, and it is one of the things we won. Parliament by its deliberate judgment during the passing of the Act of 1911 took out from the Bill, as it then was, the power of the approved societies as such to interfere with the administration of medical benefit, and placed it in the hands of other bodies. It has been discovered that, in respect to that Act and Acts which have been passed since, the approved societies have in fact got into a position which was not exactly foreseen, and which on technical grounds they are using for all they are worth in order to achieve by this other method the position they lost in 1911 of being the controllers and dominating factors in this service. We are willing to negotiate with the properly constituted representatives of the community as to what the terms and conditions of service shall be, but we shall never submit to the views which the approved societies have taken of the national needs. We believe them to be narrow views, not to the advantage of insured persons, and not conforming to what ought to be a really effective national insurance service. We will never consent to take those narrow views, nor will we consent to be made subservient to any particular section of the community, though we are still willing to negotiate with the representatives of the community as a whole.

Difficulty of Negotiation with Approved Societies.

There are one or two other points in connexion with the approved societies which I should like to take. We have heard statements made as to what their position is with regard to the National Health Insurance Fund and with regard to the effect any increase of our remuneration above 7*s.* 3*d.* would have upon that fund. We have discovered that in spite of all our attempts to arrive at agreements with representative members of approved societies, whom we have met in their representative as well as in their individual capacity, it is futile to make any arrangement with them or to come to any agreement with them, because directly the opportunity occurs they go back upon the arrangement and do not adhere to the agreement. There is one gentleman who has been very busy speaking for the approved societies, Mr. Rockliff, and there is another who has lately stepped into the fray—I am sorry to say—Mr. Canter. Mr. Rockliff, in a letter to the *Times*, made the statement that if more than 7*s.* 3*d.* were taken out of the contribution for the doctors it could only be at the cost of depriving the insured population or of reducing the sum for benefit obtainable by them out of that contribution. Again he stated that if 8*s.* 6*d.* were given to the doctors the whole additional surplus expected to be shown would be appropriated to the advantage of panel doctors instead of going to increase the benefits to the insured. Mr. Rockliff stated, "It [the Minister's] is a most improper proposal." Mr. Canter repeated the protest he made against the approved societies paying more than 7*s.* 3*d.* for the kind of service given by insurance practitioners, and he added a further protest against the doctors being subsidised out of what the approved societies called the "hidden millions." I have in my hand a document in which this paragraph occurs:—

> "We agree that the service would be such as to justify a capitation fee to the doctors of substantially the present amount [that is, 9*s.* 6*d.*] without ruling out of the present consideration any claim by the medical profession for something beyond this and we have satisfied ourselves that the National Health Insur-

> ance Fund in the aggregate contains sufficient money to meet the cost without lowering or endangering the provision of the other benefits, whether normal or additional, to which insured persons are entitled."

That is signed by Mr. Rockliff—and Mr. Canter! Those statements have been made repeatedly, and they seem to me to be in absolute and direct contradiction to the statement which was made by the same men in their representative capacity in a document embodying the result of discussions we had had with them. There were those who told us at the time that we were wrong in having those discussions. I confess I am inclined to believe now that the people who told us so were right. ("Hear, hear.") At all events, the fact that we did have those discussions showed the extreme lengths to which we were prepared to go to arrive at an amicable conclusion. And this is the result.

It may be remembered that towards the end of last year the approved societies were engaged in a campaign to prevent their administration allowance, which had been 4*s.* 10*d.*, being reduced to a lower figure, and it has been interesting to look through the files of their journals and read their speeches, and to find how closely their arguments correspond with some that we are using to-day. In the first article in the *National Insurance Gazette* for Sept. 23rd, 1922, we read:

> "On this point—the point that the present administration allowance to approved societies should be continued for another twelve months—we must say at once that it will be idle for approved societies to then contend that the doctors' capitation fee should be reduced to something like the pre-war figure while approved societies should have their allowance maintained at a larger figure."

It is still being continued, and, idle or not, the contention is made that the doctors' fee should be reduced. Again, in a later number of the same publication:

> "I feel sure that the officials who have the working of the approved societies will resent any reduction from the present administration allowance, and that whatever might be gained in pounds, shillings, and pence would be lost by a more or less unwilling service. The proper administration of health insurance requires the spirit of public service and social work, and often this evaporates in the presence of a real grievance about pay."

Again, the approved societies are now contending that any extra money above 7*s.* 3*d.* which is received for the doctors' capitation fee is so much withdrawn from the additional benefits and other benefits which insured persons will be able to enjoy. The point was, of course, made in some quarters that if they maintained the administration allowance at a higher figure than was necessary there would be less money in the fund to supply insured persons with additional and other benefits, and the statement made by the most authoritative person in the approved society world at the National Conference of Industrial Assurance Approved Societies last December was this:

> "I go further and say that it is wrong for the societies to be bolstered up as regards the work of administration by and out of private moneys when at the same time increased benefits are being given. There is a good maxim which says, 'You should be just before you are generous.'"

That shows the position of mind of exactly the same people who are talking in that way about our attitude to-day when they are faced with the possible reduction of their own salaries and a certain moderate reduction of administration allowance. It did not seem to them iniquitous that they should be paid a proper fee, despite the question of additional benefits which might otherwise be given to the insured person. To-day the only argument which they are using, and which is going home to the public at all, is that we are trying to steal from insured persons moneys going to their benefit, and appropriating those moneys into our own pockets. That is completely answered by the statement which they themselves made when the argument was used against them less than nine months ago. (Applause.)

I will pass from this, and point out that all this year we as your representatives—the representatives of insurance practitioners—have been trying to the utmost to cultivate friendly relationships with the officials of approved societies and others who have a legitimate and proper interest in the smooth working of the insurance system. We have met every criticism which they have offered, and have made constructive proposals for improving the service. They have acknowledged to us over the table repeatedly that all the things which they have considered important have been given by us and met by us in a perfectly proper way in the new terms of service we have arranged. But there has not been one word of public acknowledgment of that by the representatives of the societies since this controversy began. Indeed, all the implications have been that the service in their opinion has been a bad one, that no improvements are going to be made. They have not had the honesty to say that these improvements have been agreed to, offered and suggested in many cases by ourselves. In that atmosphere what can you do more to cultivate friendly relationships or an amicable agreement? ("Hear, hear.")

The Way to Obtain Negotiation.

The position is extremely simple. The Minister has been impressed by what the approved societies have told him: on the one hand that they have immense political pull and power, on the other hand that the doctors—I am quoting—"have not an ounce of fight in the lot of them" ("Oh!"), and that he can safely ignore the medical profession in any negotiations which take place between him and the societies and in any decisions he may come to. As to the proposals now made, however economically unjust, however socially disastrous, however detrimental to the honour of the profession, we must either submit and accept them immediately, or we must take up the only remaining solution of conflict. (Loud applause.) There is no alternative. Arbitration is ruled out, negotiation without conflict is ruled out. We have made a last attempt to see whether it is possible to negotiate with the Minister in his responsible capacity, and we have been told in a way which leaves no doubt whatever that a condition precedent to any resumption of negotiations is that we must show the Minister that he cannot get, on his present terms and in present circumstances, the satisfactory service which he desires. Therefore, in the opinion of the Insurance Acts Committee—the unanimous opinion—we are bound to enter upon this fight. To submit now would be to submit to what is for us economically unjust, for the nation bad, and for the profession fatal. (Applause.) But it is for you to decide to-day whether that is the better of the two alternatives. To accept leaves us in the position I have indicated; to fight and to fail would leave us in that position also; there is only one thing to do, in the opinion of the Insurance Acts Committee, and that is to fight and to succeed. (Cheering.)

Let me tell you what I mean by success in this fight. The fight will be won in all essentials when we have got the requisite number of resignations. The mere fact that we have succeeded in doing what we set out to do will have won this fight in all its essential respects. If we do not do it, our position as a fighting force is, of course, gone for evermore. Not only that, but if we do not do it, our position as a negotiating power is reduced to its lowest level for evermore. We leave the approved societies in the field with their claims (however unsubstantial) acknowledged, impressed not only upon their own minds but upon the minds of the governing authorities and the public of this country. The only salvation for us is to fight and to succeed. If we get the requisite number of resignations we shall be able to go to the Ministry and show that they have been secured. We can say to the Minister, "Are you prepared now, now that we have shown the approved societies that they are wrong in their estimate of us, and that you have been wrong in your doubt of us—are you prepared now to open negotiations around a table in order that we may arrive as sensible men at some peaceful solution?" I am absolutely confident that the Minister's reply to that request will be, "Yes, in this position I am prepared to negotiate." Then we shall go in to negotiate. Those negotiations must result in an offer somewhat better than the present one, and the result will show that we have been standing up for the insured persons' interests, the national needs, and the honour of the profession. We shall be able to go to the Minister and negotiate and come back to you with the result of those negotiations, in the form of a proposal which you may be able to accept or may not be able to accept, which we may be in a position to recommend you to accept or may not be in a position to recommend you to accept; but at all events our fight will be won, and the Minister and the public will realise that we care much less about sixpence here or sixpence there than we do about ensuring a good national service and maintaining a free and honourable profession. (Loud and prolonged cheers.)

Debate on Dr. Brackenbury's Statement.

Dr. Brackenbury's address was warmly applauded and at its conclusion it was decided to send a substantial précis to the press and a copy to every panel practitioner in the quickest possible way. The motion:—

> That this Conference definitely rejects the offer of the Minister of Health of 8*s.* for five years or of 8*s.* 6*d.* for three years—

was then carried unanimously, and a rider regretting that the Minister had not seen his way to accept arbitration was accepted with few dissentients. A further resolution was then passed leaving all details of negotiations regarding capitation fee in the hands of the I.A.C., and pledging the Conference loyally to follow the instructions issued by that Committee, which is the executive body.

The Position of Rural Practitioners.

Dr. Brackenbury then moved that any agreement with the Ministry or the Scottish Board on the question of the capitation fee be subject to agreement being arrived at with regard to the special circumstances of rural practitioners. He pointed out that in the lowlands of Scotland a relatively small sum of money was set aside for certain exigencies of rural practice, such as to enable a practitioner to obtain a locum during study absence, and that the position of rural practitioners might be met by readjustment of the mileage grant within the two-mile area, and further consideration for the time element in rural practice. In England the Minister's sympathy had not yet eventuated in action. This motion was carried unanimously.

The National Insurance Defence Trust.

The present position of trust funds was stated, Dr. Brackenbury expressing his conviction that they would suffice for a short fight, while the subscribers could and would no doubt produce more money if and when required. He assumed that hard cases would be dealt with as they arose, and that not all legitimate claims would in fact be presented.

TERMS OF SERVICE, 1924 AGREEMENT.

On behalf of London it was moved, that in the case of an insured person desiring to transfer from the list of one practitioner to that of another practitioner, he should be required to sign the medical card in the appropriate space (or where unable to write, to make his mark in the presence of a witness) and that insurance committees should not accept any cards not so completed. This would safeguard, if not entirely prevent, trouble in regard to touting. The motion was carried.

A motion by Walsall that a doctor should not be able to accept a panel patient who was being attended by another doctor during an illness was lost. It was felt that the situation was one not likely often to arise.

Medical Service Subcommittees.

Newcastle-upon-Tyne moved that no body on which laymen sit should have power to hold inquiries as to the correctness of any treatment given or advised. It was, however, pointed out that the usual practice of Medical Service Subcommittees throughout the country is to defer to the medical members of the committee in purely professional matters, and the motion, though passed, was referred to the I.A.C., as also a motion by Bury to obtain the power to request witnesses to sign a declaration of the truth of their evidence. A motion by Buckinghamshire asked the I.A.C. to take all possible steps to arrange for deputies being appointed for members of these Subcommittees. While it was often difficult for busy practitioners to attend regularly, the approved society officials were always present. It was doubtful whether deputising at present was strictly legal. A representative created mirth by stating that, in his area, if only one medical member was present, he faded away, so that the subcommittee could not hold inquiry.

Certification.

It was agreed to press for a verbal change in the new form of voluntary certificate, which should read "Insurance practitioners, not being under obligation to issue certificates, are *entitled* to charge fees in respect of the issue thereof," instead of "are *not debarred* from charging fees," as suggested by the Ministry. The Conference unanimously supported the I.A.C. in their refusal to accept the obligation of stamping certificates with the name and address of practitioners.

Charging of Fees.

A motion was tabled by Bury to the effect—

> That this Conference is of opinion that while an insurance practitioner ought not to charge an insured person on his list a fee for any service to which the insured person is entitled, yet he should be free to charge an insured person, who is on the list of another practitioner, for all services rendered, except in the case of emergency.

Dr. Brackenbury pointed out that this was one of two important matters in which agreement had not been reached with the Government. Approved societies took the view that "under no circumstances whatever" should an insurance practitioner charge a fee. The I.A.C. had reached the conclusion that the matter could not be dealt with simply by legal enactment. Two classes of legitimate claim presented themselves: (1) that of the patient who, without desire to change his panel doctor, wished to have the opinion of another practitioner on the panel; and (2) that of the person unwillingly insured under the Act, who refused altogether to take advantage of its provisions. This and other resolutions of cognate purport were referred to the I.A.C.

ORGANISATION.

After discussion of a motion by Kent, that all energies should be immediately devoted to a comprehensive Parliamentary campaign, supported by every possible action through the press, a careful statement of the case against the approved societies was made by Dr. **Gordon Ward**, in which the following were set out as Points for Discussion with Members of Parliament, Employers, Insured Persons, and Taxpayers.

1. The funds raised by the authority of the National Health Insurance Acts are generally held to have been primarily intended to meet the cost of a weekly payment during sickness (sickness benefit) and of the provision of medical attendance (medical benefit). Maternity and sanatorium benefit were also included from the first. It would appear that all these benefits ought to form a first charge on the funds. The approved societies dissent from this attitude and pretend that they are entitled not only to claim as their own any surplus which may accrue but also to decide how much shall be set aside to meet the primary charges named. They commonly assert that the sums required for the adequate remuneration of doctors can only be secured by depriving insured persons of other benefits—e.g., hospital, dental, and optical—to which they are entitled. It is impossible for practitioners to accept the position of residuary legatees who can only benefit when all other claims have been met.

2. The rates of contribution at present exacted from employers and insured persons are in excess of those needed to satisfy the primary requirements of the Acts as set out above, and very large surpluses have been accumulated. In the statement of balances issued in 1923 but for the year ending Dec. 31st, 1921, the total balances shown are £124,075,481. Of these £56,704,084 appear to be paper credits only and should probably be subtracted from the total, leaving balances at that date of £67,371,397. The accounts are not in all respects easy to interpret, but it cannot be doubted that further credits have accrued since 1921 and that the whole represents a very severe tax on industry at a time when any such tax ought if possible to be avoided.

3. The societies claim that all surplus funds are to be regarded as the property of various individual societies and that they are entitled to administer them in a way which, in fact, provides substantial additional benefits for some, while others (who are compelled to pay the same contributions) obtain only the statutory minimum of benefit. Although their claim can be supported by a sufficiently ingenious reading of the Acts, it remains certain that the present developments were not contemplated when the original Act was passed and that a system providing unequal benefits but compelling equal contributions is absolutely indefensible.

4. The ninth report on the work of the National Insurance Audit Department issued in 1923 and covering the audit for the year 1922 shows that in the period under review 9917 certified accounts of approved societies and branches were issued. The payments involved amounted to £14,560,682. Of these 9917 accounts no less than 4766 were certified subject to reservation or, in other words, showed irregularities. The number of cases in which fraud seems to have been in question was only 54 and the total sum involved (so far as ascertainable) only £4068, but it is evident from these figures that very large sums of money raised by compulsory contribution from the taxpayer, the employer, and the insured person are being dealt with in a way that would not for one moment be tolerated in any commercial undertaking.

5. The organic connexion between the State-provided or "approved" societies and their parent industrial and profit-making concerns (which connexion consists in the use of the same offices and officials and agents for both sections) is so

close that it seems doubtful whether the advantage of State aid can possibly be confined to the State sections. It will be noted that in the report of the Audit Department above referred to there is a "Statement of amount of payments (excluding investments) audited in the year 1922," and this shows a total of benefit payments amounting to £11,103,828. The total payments for administration were £3,456,854, so that in round figures every £100 of benefit cost £30 to distribute. It would appear probable that a less expensive system of distribution could be devised by stricter methods of control.

6. The so-called "representation" of insured persons by the approved societies does not, in fact, entitle them to speak on their behalf, inasmuch as insured persons have no sort of effective voice in the affairs of the societies to which they are forced to belong as a condition of obtaining benefit. Although a complaint against a doctor is very properly subjected to full investigation, it remains anomalous that the very much more frequent complaints against approved societies remain uninvestigated and the complainants unsatisfied—a fact to which every panel doctor can testify, since the insured person usually brings his complaint to the doctor and asks his advice as to how delayed or refused benefits can be obtained.

7. The existence of a class of "post office" or "deposit" contributors who are deprived of the benefits of insurance is impossible to defend. These persons are only to draw out as benefit the precise sum which each individual has paid in. Many deposit contributors remain so from choice since they are persons who have no desire to be insured and do not intend to avail themselves of benefits but are nevertheless technically liable to pay contributions. But this class also contains those who are too ignorant to face the formalities necessary to join a society or who have been refused admission to societies owing to their being in indifferent health and so likely to prove a charge upon the funds. These latter are often persons of deplorable social position and almost entirely devoid of education, and are thus particularly in need of that assistance from the State which the Acts were meant to provide but which is nevertheless withheld from them. Their position could be remedied by the formation of a State society, but if any such society were formed it would probably attract the majority of the insured population and thus damage the position of existing societies. It may be that this is the real reason which has led to the continued existence of the deposit contributor class.

8. Purely destructive criticism is of little avail unless it is also possible to point out the required remedies. It seems evident that the State ought to resume direct control of the expenditure of all surpluses accruing under the Acts. It would probably be necessary to retain the personnel of the societies as distributors of benefit, but they should be subject to at least the same degree of supervision and control as is found to be desirable in, for example, a sub-postmaster or any other part-time employee of the State. The whole of the anomalies pointed out above are directly traceable to this lack of control and would be eliminated almost automatically by the re-assertion in connexion of the National Health Insurance Acts of the old principle that there should be no taxation without representation. It is apparent at the moment that, for example, the employer who finds much of the money has even less share than the insured person in determining how it shall be spent.

Following Dr. Ward's statement, it was decided with but three dissentients to appoint a committee forthwith to conduct a publicity and Parliamentary campaign and report to the I.A.C. Membership of this committee, suggested from the chair, was as follows: Dr. H. B. Brackenbury, Dr. J. W. Bone (Luton), Dr. F. G. Layton (Walsall), Dr. C. F. T. Scott (Middlesex), Dr. G. C. Garratt (Chichester), Dr. E. A. Gregg (London), and Dr. Gordon Ward (Kent). A motion by Liverpool to the following effect was referred to this Committee to consider:

> That this Conference strongly urges every practitioner to make individual protests to the Minister of Health, the local Member of Parliament, and to any political association to which he may belong, and instructs all Panel Committees to organise protests in their separate areas.

The Conference rose at 6.30 P.M.

ELSIE INGLIS MEMORIAL.—The corner stone of the Elsie Inglis Memorial, The New Hospice, Spring Gardens, Abbeyhill, Edinburgh, was laid on Oct. 18th by Viscountess Novar. The hospice occupies a site overlooking King's Park, with outlook to Arthur Seat and Salisbury Crags. There is accommodation for 40 beds, and the hospice, when completed, will form a valuable addition to the maternity and child welfare institutions in the city, and will be a fitting memorial to a brave woman.

THE PANEL CRISIS:

THE SITUATION IN THE MANCHESTER DISTRICT.

(FROM A SPECIAL COMMISSIONER.)

ON the principle that what Lancashire thinks to-day the country will think to-morrow, I visited Manchester and Salford during the week-end, with a view to finding out the attitude of panel practitioners and others in face of the failure of the insurance medical service to obtain satisfactory terms and conditions of service for 1924. Manchester has a panel of some 250 practitioners, with another 105 or so in Salford, and although the executive officers of the panel themselves are for the most part busy practitioners, they were ready to talk over a momentous position. I found them unanimous practically and firm. The firmness was quite unmistakable. Whatever the outcome, the doctors in the area have decided to grasp the opportunity of freeing themselves from friendly society control. Not that there has been any difficulty locally for years past in working the Insurance Acts harmoniously. No doubt everything is made easier by the system of payment on the principle of visits paid, the doctors' quarterly accounts being cut down in Manchester to a basis of average visits, and in Salford to an artificial limit conveniently described as "the bogey figure." The system has admitted not only of free choice of doctor, but of free change of doctor as often as desired, with the complementary right of the practitioner to get rid of an undesired patient. All the parties to the local working of this scheme meet on the Insurance Committee, and have found no difficulty in composing their divergencies by round-table conference and mutual give-and-take. Complaints referred each year to the Medical Service Sub-committee scarcely run into two figures. The chairman of the Insurance Committee made it quite clear last week, and carried his National Association with him, that it is not for insurance committees to take sides in the quarrel, their duty being to fight for an adequate service. The fear of the doctors is quite definitely that the friendly society officials have reasserted, or have endeavoured to reassert, their right of controlling the conditions and remuneration of medical service at the centre; the fear, in fact, that the control by friendly societies of medical benefit, which was definitely taken out of their hands by the Acts of 1911 and 1913, was again to become operative. This is a sequel to the arrangement made by Sir Alfred Mond in sanctioning the payment out of accumulated contributions of part of the capitation fee when the Exchequer grant was withdrawn by the Geddes axe. Sufficient resignations had already been tendered by the end of last week to make it evident that the required quota would be reached, and Manchester is settling down with quiet and grim confidence, not altogether unmixed with satisfaction, to a fight in which the memories of 1912 are still present. I spoke with the first practitioner to go on the Manchester panel in 1912; he was quite prepared if need be to come off in 1924.

The plan of campaign on Jan. 1st, 1924, is quite simple. Manchester and Salford could easily have organised a scheme for the collective treatment of insured persons by the local profession, on the analogy of schemes in full working order at Leicester and Southampton; but to do this would be to impose great difficulty on surrounding areas where organisation is less perfect, and the decision has been taken to revert on Jan. 1st to the conditions of private practice. No patient will be accepted for a lesser fee than 3*s.* 6*d.* in Manchester, but no practitioner will refuse to treat a case of urgent illness without fee, wherever the necessity should arise. Hardship would, it is felt, not be so manifest in Manchester, where, in spite of a lamentable proportion of unemployment, the working class on the whole is not badly off. Any tendency to refer patients wholesale to the part-time Poor-law medical officers would not prove acceptable to these practitioners, who are also without exception on the panel. The hardship would fall rather on individual doctors, especially the comparatively few who are dependent solely for their existence upon a large panel. Although no doubt the individual fee per patient would be higher—for in the Manchester scheme practitioners are actually paid only some three-fourths of the sums to which they are entitled on the basis of the model fees—yet attendances would certainly drop off in greater or less degree, young people of both sexes generally would be loath to come if a fee was to be charged, minor ailments would remain unattended, and in fact all the early preventive work which has been growing up unobtrusively under the Acts would drop out.

How long would such a struggle last? Manchester is not optimistic in regard to the Minister yielding forthwith, even when evidence of the determination of the medical profession is submitted. But insured persons will, no doubt, bring pressure upon their friendly societies to come into line, even before the seriousness of the position is brought home to them in the New Year, for the doctors' case already has widespread sympathy among insured patients, "Surely, Doctor, you are not going to take less than you do now," being frequently heard. The difficulty is realised in stating an issue which cannot readily be explained in popular terms. No doubt 8*s.* 6*d.* is regarded in the Manchester area as an insufficient sum for services rendered. So much is this the case that, as was to be feared, a number of the practitioners with smaller panels—men whose presence on the lists is particularly valuable in proof of the all-round quality of service—have decided in any case not to renew their agreement with the Insurance Committee; but it is not easy, in an area where feeling is friendly all round, to evaluate the fear of central interference from the approved society representatives, which Manchester is as sensible to as practitioners in less organised districts.

Can the resistance be effective? There is, I gather, a large local relief fund quite apart from the National Insurance Trust Fund, from which the hard cases would be relieved, and on the financial side it is felt that the Minister of Health is unaware of the strength of the position. Experience has shown that it is not difficult to keep up a loyal standard of a minimum fee per visit or surgery attendance, although more difficult to do so in the case of any contract arrangement.

A curious difficulty arises in enlisting the sympathy of the women for the insurance principle, for, even in an area where the serious aspect and determination of the Mancunian at once strike the southerner, women are found not readily comprehending that principle. When in health they are apt to resent the payment of instalments which do not seem to them to result in any material return. At any rate, the domestic servants in Manchester—for there still appear to be some—are hostile to medical benefit under the Act, and this spirit has been in evidence often and elsewhere. But these comprise the only section of the community, it would seem, who desire to "scrap the Acts." In Manchester the medical men and the public alike accept the insurance principle, the medical men only wanting to have proper conditions of service.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Cameron Prize Lecture: The Story of Insulin.

Prof. McLeod, of Toronto, delivered the first of two lectures on Oct. 16th in the University New Buildings, Edinburgh. He said that he proposed to give a review of the investigations which had led to the introduction of insulin as a recognised therapeutic agent. The problem with which they were concerned was the nature of the fundamental factors which control carbohydrate metabolism. Prof. McLeod briefly outlined the well-known facts of the breaking up of carbohydrates into carbon dioxide and water, and how this was influenced and controlled by an internal secretion of the pancreas, to which Sir Edward Schafer gave the name insulin. He told how he and his co-workers had eventually managed to obtain this substance free from proteolytic enzymes by the process of acid-alcohol extraction of fractional precipitation The next step was to study the effects of insulin on experimental animals. In depancreatised dogs insulin replaced something which was absent and controlled over-production of sugar, so preserving the balance in the blood. In normal animals it was a toxic agent having, as it were, the effect of an overdose. The advantage of using depancreatised dogs rather than experimenting on diabetics was that the latter are not completely depancreatised and consequently an unknown factor is involved. Best and Banting in thei first experiment obtained a definite fall in blood-suga and this was accompanied by a lower output of suga in the urine, so that the sugar was used by the animal They next set to work to find out by comparing intake with output how much glucose a unit of insulin could cause to be metabolised. Thus, if a dog on an intake of 145 g. of sugar used 105 g. with 20 units of insulin and 135 g. with 30 units, the additional insulin has presumably accounted for the extra 30 g. of sugar used and the glucose equivalent, as it is called, would be 3 It was important from the clinical standpoint to determine this glucose equivalent. It was not constan in any one case, and was found to be considerably lower in diabetics than in the experimental animals It became progressively smaller as the dose of insulin increased according to a definite curve, so that insulin in this respect behaved as an enzyme. This observation suggested that clinically a slow absorption of small amounts as from inunction or the alimentary tract was more desirable in obtaining the maximum effect than the present hypodermic method. The glucose derived from carbohydrates was apparently more easily metabolised than that from other sources, which possibly accounted for the lower glucose equivalent in diabetics who derived their supply to a considerable extent from protein. Insulin also acted on the other end of the chain, bringing about the deposition of glycogen in the liver and muscles. It acted, too, on both ends of the fat metabolism chain, reducing the lipæmia and fat excess in the liver at the one end and at the other bringing about the complete oxidation of butyric acid. The lecturer pointed out that this latter action was indirect and quoted the well-known illustration of the fats being burnt up in the carbohydrate fire. The ketone bodies in diabetes might be regarded as the poisonous smoke of incomplete combustion. The influence of the pancreas on fat metabolism was a problem of great interest and importance.

In the second lecture Prof. McLeod began by discussing the effect of insulin on experimental forms of hyperglycæmia. These he classified in three groups: (1) nervous, (2) asphyxial, (3) pharmacological. Claude Bernard's classical experiment of puncturing the floor of the fourth ventricle furnished an excellent example of the group (1). There was also in this group sympathetic stimulation, either direct electrical or indirect by adrenalin. Ether and phloridzin respectively were examples of the group (2) and (3). Insulin controlled all these forms of hyperglycæmia. That this was not a simple reaction in the blood was indicated by the fact that much mor glycogen was recovered from the liver of an anima to which insulin had been given along with epinephri than from that of one which had had epinephri alone. An interesting and at present inexplicabl fact was that only 60 per cent. of injected glucos was recovered in the body 15 minutes later. It woul seem that insulin brought about the formation of a intermediary substance between glucose and th end-products, carbon dioxide and water, which wit our present analytical methods we are unable to detec Prof. McLeod went on to deal with the effect of insulin on normal animals. In well-fed animals, i which there was a plentiful store of glycogen, th blood-sugar curve returned in about three hours to its normal level, whereas in starved animals, which lacked this store, the return was very much slower. This had a practical bearing in indicating a possible danger in the insulin treatment of severe diabetics. The two curves corresponded in the first half-hour, which might seem to indicate that the process takes place in the blood. But in vitro the glycolysis curve was unaffected by insulin. The effect would seem, therefore, to be produced in the tissues, and this was supported by the fact that insulin greatly increased the rate of glycolysis of the perfused mammalian heart. It was as if a vacuum were created in the cell and filled up again from the blood. This "vacuum" was in all probability the result of increased carbohydrate metabolism, though the experimental evidence of this was not absolutely unimpeachable. Non-insulin normal rabbits showed higher storage of glycogen than insulin ones. The increased carbohydrate metabolism resulting from insulin led to a sparing of protein metabolism. The lecturer went on to speak of the source of insulin. He reviewed the known facts concerning the islets of Langerhans. In the lower animals, such as the skate, the islet tissue is definitely arranged along the ducts and appears to be an outgrowth of the epithelium of the ducts, whilst in some fishes the islet and zymogenous tissues are quite separate. In these the islet tissue was present as a number of small glands, one of which, larger than the rest, was known as the principal islet. As much as 25 units of insulin had been obtained from one of these islets. The cod and the halibut were providentially provided with large principal islets, and, as these could be quite easily collected by fishermen when cleaning the fish, there would seem to be every hope of a substantial reduction in the cost of production of insulin.

University of Edinburgh: Retirement of Professor Alexis Thomson.

It is a matter of great regret that Prof. Alexis Thomson, C.M.G., has been compelled through ill-health to retire from the Chair of Systematic Surgery, to which he was appointed in 1909. In appreciation of the place he held in the estimation of the undergraduate a former pupil writes in *The Student*, the official students' magazine of the University:—

> "Some of us will long remember the strange feeling of despondency we felt on hearing that Prof. Thomson might retire from the Chair of Surgery. He has filled, and will continue to do so, a very conspicuous place in the tradition of the Edinburgh school, and in the conversation and memories of undergraduates. Never has any lecturer occupied a more affectionate and familiar place in the memories of his students. . . . Although severed to his intense regret, from the detail of teaching surgery, his name will long remain as an impulse to progress. One of the greatest benefits students have derived from Prof. Thomson's lectures, and one which he was never tired of emphasising, was his conception of the evolutionary nature of surgery. His teaching was valuable, not for the number of facts that he enunciated, but for the angle from which he regarded surgery, not as an abstract collection of immutable rules, but the practical art of relieving disease based on physiological principles."

Royal Medical Society of Edinburgh.

The inaugural address of the 187th session of the Society was delivered in the Society's Hall, Melbourne-place, on the evening of Oct. 19th by Sir William Leishman, K.C.M.G., Director-General of Medical Services.

Royal College of Physicians of Edinburgh.

At a dinner given by Prof. George M. Robertson n connexion with the Morison lectures, Prof. Robertson poke on the Centenary of the Delivery of Special Courses of Lectures on Mental Disease.

WEST RIDING ASSOCIATION OF GRADUATES OF THE UNIVERSITY OF EDINBURGH.—The annual dinner will be held in the Great Northern Hotel, Leeds, on Nov. 9th, t 7 P.M. It will be preceded by the annual general meeting at 6.30 P.M. Further information may be obtained rom the hon. secretary, 103, Manningham-lane, Bradford.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following table gives some of the principal health statistics for three cities during 1922. It will be noted that Sheffield compares favourably with the other two for the death-rate from respiratory diseases and influenza, probably for the reason given by Dr. Wynne, that influenza was prevalent in the last quarter of 1921 in Sheffield and not in the first quarter of 1922.

City.	Estimated population (R.G.).	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Respiratory with influenza.	Infant mortality		Maternal mort. in childbirth.
							Legit.	Illegit.	
Sheffield	522,600	20·7	11·7	1·2	1·2	2·3	80	119	3·6
York	84,980	20·0	12·3	1·2	1·2	2·5	69	269	6·4
Lincoln	66,930	18·4	12·1	0·9	1·2	3·6	(80)*		4·0

* The figure in brackets gives the undivided infant mortality rate.

Sheffield.

Dr. Fred. E. Wynne reports that the general death-rate and the infant mortality-rate were the lowest ever recorded. The Sheffield death-rate was for the first time lower than that for England and Wales. This is partly due to the fact that the influenza and pneumonia epidemic occurred in Sheffield during the last quarter of 1921, whereas in most parts of the country it occurred in the first quarter of 1922. Eleven cases of small-pox were notified during the year, all of the mild type characteristic of recent outbreaks in the Midlands. All the patients made a good recovery. The war increase in tuberculosis deaths amongst both males and females has disappeared. The lowest death-rate from tuberculosis was in 1920, and the two subsequent years show a slight increase. Thus the deaths in 1920 were 590, in 1921 619, and in 1922 636. Dr. Wynne combats the suggestion that the reduction in infant mortality merely postpones the deaths of infants to a slightly later period of life by showing that the mortality at ages 1–5 has declined pari passu with the mortality during the first year of life. He further shows that, owing to the decreased numbers of deaths of infants from diarrhœal and respiratory diseases, the number of deaths of weakly or degenerate infants with a bad heredity, included in the congenital causes group of prematurity, debility, &c., now form a greater proportion of the total infant deaths. This indicates that the infants who are being saved are not the weekly and degenerate ones.

The number of houses erected during the year was 979, of which 801 formed part of a municipal scheme. Overcrowding is still deplorable and the city treasurer has 4000 families on the waiting list for municipal houses. Owing to the shortage, there has been much sub-letting by tenants of the corporation and endeavours are being made to check this and to prevent undesirable conditions arising on the corporation housing estates. Much attention has been given during the year to the repaving of back-yards, and Dr. Wynne emphasises the fact that "when an unpaved and dirty back-yard is put in good condition the effect is to improve the sanitary condition and cleanliness of the whole interior of the houses using such yard." As the cost falls entirely on the owner, the progress of this work is difficult in many cases at the present time. A scheme is under consideration by which, when necessary, the corporation would do the work and recover the cost from the owner in instalments. Dr. Wynne believes that such an arrangement would constitute, without cost to the rates, an important sanitary reform.

Investigation of the causes of stillbirths does not indicate that syphilis has been a frequent factor. Of 142 cases investigated, 23 were first pregnancies and in 62 cases the mother had previously only had living children. It is suggested that the present unemployment, with its resulting constant worry and malnutrition, has been a factor and that "in many cases there is no apparent cause, which is very suspicious and unsatisfactory." The number of persons dealt with for the first time at the V.D. clinics has declined from 2418 in 1920 to 1399 in 1922. The number of attendances per patient shows a satisfactory increase. The cost of the scheme per person dealt with for the first time was £3 18*s.* 3*d.* in 1920 and £4 16*s.* 1*d.* in 1922. Dr. Wynne sees "no reason why persons who can afford to do so should not pay the whole or some part of the cost of their treatment."

There are 2350 stalls for dairy cows in the city of Sheffield, and in these stalls 23 cows were found during 1922 with tuberculous udders. It has to be borne in mind that the Sheffield cowkeepers know that their cows will be subjected to regular veterinary examination and consequently have a special reason for trying to buy cows free from sign or symptom of tuberculosis. The 1922 experience of one tuberculous udder per 100 stalls is more or less similar to the experience of former years. One may be justified in drawing the inference that the rate of one tuberculous udder per annum per 100 stalls occupied by milk cows would be considerably exceeded in districts where there is no systematic veterinary inspection. An interesting feature of the Sheffield scheme is the use made by the veterinary staff of the microscopical examination for tubercle bacilli. Thus, in 1922, 44 country cows and 18 city cows were found to be suffering from tuberculosis of the udder by microscopical examination of the sample from the suspicious udder. These cows were dealt with at once and the milk-supply freed from infection, without the delay of some weeks necessitated by the biological examination. The number of samples taken from suspected udders during the year was 132. Of these 61 were found to contain tubercle bacilli by immediate microscopical examination and 71 gave a negative result. The 71 "negative" examples were sent for biological examination and nine were returned as positive, 62 as negative. The immediate microscopical test therefore proved of great value.

York.

Dr. Edmund M. Smith tells us that the important events of the year were the opening of the new maternity hospital and the appointment for the first time of an assistant medical officer of health. Acomb Hall has been successfully adapted as a maternity hospital by the city engineer, Mr. F. W. Spurr. The accommodation comprises four large wards with 27 beds, four small wards with nine or ten beds, two one-bed isolation wards with separate conveniences, a labour-room on each of the two floors, a receiving room with bath, and suitable accommodation for administrative purposes. A farmhouse on the site provides accommodation for the night nurses and others. The hospital has a very pleasing general appearance and situation, surrounded as it is by ample gardens with fine shrubs and trees. The first resident medical officer is Dr. Kathleen Cass, the newly appointed assistant medical officer of health, and Dr. Louise Fraser has been appointed visiting surgeon on an agreed scale of fees. The Central Midwives' Board have approved of eight pupil-midwives being taken at a time. Maternity and child welfare work in York is carried out by the medical officer of health and his two health visitors, the Infants' Welfare Association, the dispensary, the maternity hospital, the county hospital, the school clinic, and other bodies all working together—an excellent blend of municipal and voluntary effort. Coördination is maintained by the York Child Welfare Council (founded in 1914), which comprises representatives of the various bodies interested and of which Mrs. Edwin Gray is honorary secretary. During the year ended March 31st, 1923, midwives attended about 91 per cent. of the total births in the city and sent for medical help in about 4·4 per cent of their cases. The former figure is surprisingly high and the latter as surprisingly low. Voluntary work is also a feature of the York tuberculosis scheme. The care and after-care committee known as "the Tuberculosis Crusade Committee" raises funds for the provision of financial help, extra food, clothing, beds, bedding, nursing, &c., for those in need of assistance; also for loan of shelters and bath-chairs, payment of expenses at convalescent homes, and assistance towards training for or obtaining more suitable employment. There are 1480 midden-privies in York and over 2700 waste-water closets, but the provision of the latter is now discouraged. During the last 22 years 5556 midden-privies have been replaced by water-closets, either voluntarily or by order under Section 91 or Section 36 of the Public Health Act, 1875. It was proposed during the year to construct a swimming pool in the Rowntree Park, to be fed by river water. The safety of the river water for the purpose was doubted; in any case it would have needed filtration so it was ultimately decided to supply the pool from the water company's mains.

The new houses built during the year numbered 100, 97 being on the Corporation Tang Hall Estate. In December, 1922, the following proposals were adopted as regards priority for letting houses on this estate: (1) The tenant to be in a position to pay the rent; (2) the tenant to be likely to look after the house and keep it in good and clean condition; (3) subject to (1) and (2), preference to given to applicants living in unhealthy conditions; (4) subject to the foregoing, priority to be given to ex-service men and to widows and dependents of ex-service men, and, other things being equal, in order of application. Owing to the housing shortage, there has been undesirable sub-letting on the estate and the corporation have had to interfere. The York City Council have approved a resolution from Chiswick, that the Government be urged to promote legislation, requiring the payment of rates for unoccupied houses held for sale with vacant possession.

Owing to the practice having become prevalent of selling commercial borax, containing considerable quantities of arsenic, for medicinal purpose, a warning letter has been issued to all the vendors in the city.

Lincoln.

Dr. C. J. Coleman makes reference to the progress of various sanitary measures. Following the big scheme of sewerage in 1921, another large scheme for the relief of the High-street sewer has been put in hand. Cesspools to the number of 43 have been abolished and 77 houses, which formerly drained into cesspools, have been connected to the sewer. The danger from contaminated water-supplies still continues in the Foss Ward, where 11 houses have been connected to the city water-mains. The greatest danger is in Doddington-road and an extension of the water-main is needed to give these houses a safe water-supply. Dr. Coleman complains of the nuisance caused by the streets being filled with the heavy unpleasant acrid smoke given off by the increasing number of steam motors used for haulage purposes. So far no active steps have been taken, and the cause is said to be largely due to the use of poor coal. There was one case of mild small-pox in November which necessitated the opening of the small-pox hospital. The question of increasing the efficiency of this hospital is at present under consideration. The number of new houses built last year was 94, 75 under a housing scheme and 19 by private enterprise. There is still a great shortage of houses and consequent overcrowding, and the existing position is a danger to the health of the city. A representation as to certain insanitary areas has proceeded through the usual routine and an inquiry by the Ministry has recently been held thereon

CENTENARY OF THE LANCET.

To the Editor of THE LANCET.

SIR,—I should like to add a congratulatory message to the many you have received on the Centenary of THE LANCET. I am the proud possessor of the first volume of THE LANCET, which belonged to my great grandfather, and bears on the fly-leaf the bookplate, "Thomas Steele, Surgeon, Reigate, Surrey." At his death it passed with a number of other early volumes of THE LANCET to my grandfather, John Sisson Steele, M.R.C.S., L.S.A., of Reigate. I myself inherited these volumes from my father, Dr. Russell Steele, of Hemel Hempstead. Though, alas, several volumes have disappeared since moving from one house to another, I am still the lucky and proud possessor of Volume No. 1.

I am, Sir, yours faithfully,

RUSSELL V. STEELE, M.B., B.S.

Haverhill, Suffolk, Oct. 19th, 1923.

WARDROP'S OPERATION.

To the Editor of THE LANCET.

SIR,—In the very interesting Centenary Number of THE LANCET it is stated on p. 696 that the name of James Wardrop "may still be familiar from its occurrence in some text-books as the originator of the treatment of aneurysm by distal ligature."

I think that Brasdor was the first to suggest distal ligature of the trunk of the artery affected by the aneurysm. He did not himself perform the operation, nor did it meet with success at the hands of others for many years. Wardrop was the first to perform the operation with success, ligaturing the carotid artery on the distal side of an aneurysm of that trunk. This was in 1825. It was, I think, with the object of giving effect to the two-fold principle of the Hunterian operation that Wardrop subsequently suggested ligature either of the carotid or subclavian artery for the cure of aneurysm of the innominate. He hoped to have a healthy portion of vessel with which to deal and he desired to lessen rather than to arrest the flow of blood through the sac.

I have not looked up the original records, and I am writing from my recollections of the lectures of the late Prof. Pirrie, of Aberdeen, of 43 years ago. He always insisted on defining Brasdor's operation as ligature of the trunk of the artery affected and close to the aneurysm, and Wardrop's operation as ligature of a distal branch.

I am, Sir, yours faithfully,

Leeds, Oct. 16th, 1923. T. WARDROP GRIFFITH.

"DEFATTED" TUBERCLE ANTIGENS.

To the Editor of THE LANCET.

SIR,—Prof. Dreyer's article on "defatted" antigens which appeared in the June number of the *British Journal of Experimental Pathology*, and to which reference had been made in recent issues of your journal, has given me more than usual interest, in that the line of his investigation corresponds somewhat closely to that which I had pursued some years back. With a tubercle antigen freed from fat by repeated treatment with ether and chloroform I had carried out a series of tests on the complement-fixation method for tuberculosis, and published my results[1] in which the technique on the preparation of the fat-free antigen was described. The specific reaction which I had obtained in the test had induced me to try it as a vaccine on tubercle infected guinea-pigs, and, later, with the kind coöperation of Dr. Guy and Dr. Elder, of Edinburgh, on tuberculous patients. The work was, however, interrupted by my departure from that town, and, unfortunately, the number of cases studied was not extensive enough to justify us recording our results. But so far as our investigation went we observed that the infected guinea-pigs which had received the tubercle vaccine survived longer than those which had not, and that the vaccine could be administered to a greater variety of clinical cases of tuberculosis and in much larger doses. The superiority of this lipoid-free antigen over other forms of tubercle antigens is also indicated in the work on the complement-fixation test for tuberculosis independently conducted by Seller and Ramsbottom.[2]

Although much has yet to be done to establish the value of any "defatted" tubercle vaccine as a therapeutic remedy, I believe as I did that a tubercle antigen, when free from lipoids, is more readily emulsified and more favourable to interaction with its antibody, in vivo and in vitro. I am therefore the more glad to see Prof. Dreyer's research on the subject, and await his further results with much interest.—I am, Sir, yours faithfully,

C. Y. WANG, M.D., F.R.C.P. Edin.

University of Hong-Kong, Sept. 15th, 1923.

THE RELATION OF GASTRIC ULCER TO CARCINOMA.

To the Editor of THE LANCET.

SIR,—In connexion with a paper on the above subject that appeared in your issue of Oct. 13th I should like to mention that for over two years a special sub-committee of the Pathological Society of Manchester, with Dr. J. H. Dible, lecturer in pathology at the University, as secretary, has been collecting pathological material bearing on the relation of gastric ulcer and cancer. This collection, in which the specimens dealt with in my paper are included, along with those of several colleagues and some obtained at autopsies, provides a body of material on which it will, I hope, be possible to base a much more comprehensive study of the problem than the cases of an individual surgeon can afford. The existence of this committee and my indebtedness to it, and through it to the department of pathology of the Manchester University, were referred to in my paper as read before the Manchester Surgical Society, but omitted from the copy sent for publication, as being rather of local than general interest. On further consideration, however, I regret this omission, and would ask you to allow me to correct it.

I am, Sir, yours faithfully,

Manchester, Oct. 21st, 1923. JOHN MORLEY.

X RAY DIAGNOSIS OF PREGNANCY: ITS MEDICO-LEGAL ASPECT.

To the Editor of THE LANCET.

SIR,—The annotation in your issue of Oct. 20th, commenting upon the decision of the French law courts in l'affaire d'Evreux, has interested me very much because I have been investigating for over 12 months the value of X rays as an aid in the diagnosis of pregnancy at different stages. By the employment of the correct technique it is my opinion that the fœtal skeleton can be clearly demonstrated upon a skiagram with absolute certainty in any case during or after the sixth month of pregnancy. Earlier than this it is more difficult but not by any means impossible, the difficulty, of course, increasing the earlier the stage of pregnancy. I have recently succeeded in proving pregnancy by the demonstration of the fœtal skeleton on a skiagram in a case which was estimated to be about three and a half months' gestation. An article which I have written on the subject of Radiography of the Fœtus in Utero, with illustrations, is appearing in the October issue of the *Archives of Radiology and Electrology*.

I am of opinion, though, that the judgment for the plaintiff against the French surgeon, who failed to employ X rays as an aid to diagnosis and who operated for a fibroid tumour and found a viable infant, was not fair, because X rays hitherto have not been employed with any degree of success in pregnancy diagnosis, and judging from the literature upon the subject, which is scanty, the surgeon might have been excused if he was not enthusiastic as to the reliability of radiography.—I am, Sir, yours faithfully,

THE PANEL CRISIS AND THE ROYAL COLLEGES.

To the Editor of THE LANCET.

SIR,—A very large number of members of our profession are now embarked upon a great struggle. Up to this point no sound has been heard from either of the Royal Colleges upon the questions at issue. Have we not a right to expect that these bodies, which are responsible for the launching of so many men into the medical profession, and to whom the public generally may look for some guidance in forming its opinion, should come into the open and officially express their views? Their support, given ungrudgingly to their brethren, could not but be a help. Further, although at this moment they are not involved themselves in the struggle, yet who knows how soon panels of "consulting" physicians and surgeons may be formed? Then, even the very presidents themselves will be in a position to say "yea or nay" to work on the panel. I do hope, before it is too late, the Colleges will officially take some part, if only a small one, in the struggle; they have allowed opportunities of service to pass by on other occasions, and there is one here ready to their hand, if only they will grasp it.

I am, Sir, yours faithfully,
LEWIS G. GLOVER.
Hampstead, N.W., Oct. 21st, 1923.

THE LISTER WARD IN GLASGOW INFIRMARY.

To the Editor of THE LANCET.

SIR,—In your issue of Oct. 13th there is an annotation dealing with the proposal to remove the Lister ward which stands in the grounds of the Glasgow Royal Infirmary. I agree with Mr. Morris in thinking that if at all possible that ward should be retained, and nobody could have argued the matter for its retention more fairly and more courteously than Mr. Morris has done. At the same time there is another side to the matter and it is this, that the ground on which the ward stands is urgently required for the purpose of building a new and thoroughly up-to-date dispensary for the outdoor department. Situated as the infirmary is in the midst of a teeming population the outdoor department is an enormous one, and the present premises are wholly inadequate. There is no other situation within the infirmary grounds on which this dispensary can be built.

The Royal Infirmary has been in deep water financially. Fortunately it has pulled through, thanks very largely to the chairman of the board of directors, to the honorary treasurer, and to the acting treasurer, but not very long ago it was quite a possibility that a portion of the infirmary would require to be closed down. The plans for the new dispensary have been drawn, and the chairman has shown them not only to every member of the board of management, but also to every member of the staff, and there has been no suggestion whatever that the plans are unnecessarily large or that the new proposed accommodation is not required. There is only one possibility of retaining that ward, and it is that ground be purchased in the immediate neighbourhood of the infirmary and cleared and utilised for the building of the new dispensary. The managers have the greatest difficulty in financing the hospital. Hitherto they have been successful, but they certainly have no money to use for the purchase of additiona ground for the erection of these new buildings. think in all fairness it is up to those who disapprov of the managers' proposed action to provide th funds for the purchase and the clearing of a site in th immediate neighbourhood of the hospital. I am no sure that the dispensary can be built away from th hospital or outside of the grounds, but I am going o the supposition that the thing is possible. Variou people of note have visited the hospital. I am sorr to say without giving the chairman or any of hi colleagues intimation of their proposed visit, an therefore making it impossible for any of the manager to meet them, and after such visits have communicate their adverse opinion of the managers' conduct to th press. I do not know the dictates of modern courtes at all, for I am old-fashioned, but it is an extra ordinary thing that these distinguished gentleme should have visited the Royal Infirmary withou ever signifying to the directors their intention of doin so. It would have afforded the managers of th Royal Infirmary the greatest pleasure to have me some of these gentlemen and to have discussed th matter in an amicable way.

I am, Sir, yours faithfully,
ANDREW FREELAND FERGUS,
Glasgow, Oct. 18th, 1923. One of the Managers.

THE UNITED HOSPITALS WINTER SPORTS CLUB.

To the Editor of THE LANCET.

SIR,—I trust that you will assist me to brin to the notice of your readers this club which wa founded to encourage winter sports amongst past an present students of all recognised medical schools i the United Kingdom. As the Grand Hotel, Griesal Bernese Oberland, was considered a success las season, it has been decided to make this the Clu Hotel for 1923–24. Our President, Lord Dawson, ha very kindly consented to give a trophy for a ski-ra to be held at Griesalp between Jan. 6th and Jan. 13t All particulars can be obtained from the manager the above hotel.

I am, Sir, yours faithfully,
J. DUNCAN LYLE,
Oldfield Lodge, Maidenhead, Oct. 22nd, 1923. Hon. Sec.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt.-Comdrs. P. G. Richards (D.) to *Excellent;* T. W Carruthers to *Cleopatra* (on recommg.); and J. B. Crawfor to *Victory*, for R.N. Hospl., Haslar.

Surg. Lt. W. Young to *Iron Duke* (on recommg.).

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. (temp. Col.) J. C. Kennedy is appointed Ho Physician to the King, and is granted the brevet rank Col.; and Maj.-Gen. D. J. Collins, late R.A.M.C., is appointe Hon. Surgeon to the King, vice Lt.-Gen. Sir C. H. Burtchael late R.A.M.C. (ret.).

Capt. J. P. Litt retires, receiving a gratuity, and is grante the rank of Maj.

Capt. H. J. Bensted relinquishes the temp. rank of Maj.

The undermentioned relinquish the acting rank of Maj. Capt. B. L. Davis and Temp. Capt. J. D. Gunn.

Capt. A. W. Dennis retires, receiving a gratuity, and granted the rank of Maj.

ARMY DENTAL CORPS.

Capt. G. W. Allen resigns his commn.

SPECIAL RESERVE OF OFFICERS.

Supplementary to Regular Units or Corps: Capt. J. F. W Sandison relinquishes the acting rank of Lt.-Col.

TERRITORIAL ARMY.

Lt. G. F. Shepherd to be Capt.

ROYAL AIR FORCE.

Squadron Leader R. J. Aherne is granted a permanen commn.

Obituary.

HARRY MICHIE, M.B., C.M. ABERD.,

HON. SURGEON TO THE SAMARITAN HOSPITAL FOR WOMEN, NOTTINGHAM.

Dr. Harry Michie, who was a well-known Nottingham surgeon, died suddenly from cardiac syncope while out shooting at Flintham on Oct. 13th. A native of Forfarshire, he was born at Edgell in 1855, and, after a successful career at Aberdeen University, graduated M.B., C.M. in 1881. For a few months he practised as an assistant to Dr. Owen Taylor at Nottingham, then returned to Scotland, and, subsequently, in 1884, started a practice again at Nottingham, where he soon gained for himself a wide reputation, which was added to by some good literary contributions. He had been honorary surgeon to the Samaritan Hospital for Women, Raleigh-street, for some 37 years, and was a past-president of the Nottingham Medico-Chirurgical Society. He leaves a widow and two sons.

Dr. P. Kinmont writes as follows of his friend and colleague :—

"With tragic suddenness Dr. Michie died in the shooting field while engaged in the enjoyment of his favourite recreation. He had left home apparently in his usual health and in the best of spirits. Suddenly, about mid-day, without suffering, without scarcely any knowledge of what was happening, he passed over to the Great Beyond. Those of us who were privileged to know Dr. Michie intimately, feel he would have preferred no other end. To me his loss is irreparable—gone is my trusty, staunch and loyal friend of the last 15 years. Countless numbers of his patients will recall with gratitude and affection their genial adviser and helper. No matter how humble the sphere of life Dr. Michie was ever ready and willing to lend his skill to alleviate suffering without thought of worldly gain. His ability and skill in his special sphere were beyond dispute and estimation. Dr. Michie's very presence in the sick room or operating theatre with those kindly twinkling eyes, that quiet voice and genial manner, was at once an inspiration to courage and confidence. In his hands we felt safe, we loved and trusted him, and he did not fail us. We cannot easily replace such a tower of strength and faithful counsellor in times of trouble."

THE LATE SIR WILLIAM RICE EDWARDS.

Sir Patrick Hehir writes to add the following appreciation of the late Major-General Sir William Rice Edwards whose obituary notice recently appeared in THE LANCET :—

"He was a personal friend of mine for over 40 years. We qualified together, were at Netley together, and on several occasions worked together in India ; our aims were similar, he on the civil, and I on the military side of the I.M.S. In 1913 he did his military training with me for promotion to A.D.M.S., and, although civil employment was more congenial to him, he went through this course most diligently, and did excellent work afterwards as an A.D.M.S. on the North-West Frontier. Edwards had wide and varied professional experience, was an ideal executive officer, and a sound and popular physician, and as Director-General of the Indian Medical Service proved himself to be one of the best administrative medical officers that Service ever had. His devotion to the I.M.S. was unalloyed by anything in the shape of personal ambitions. In his advocacy of the interests of the I.M.S. he was quite fearless ; indeed, his persistence and his firmness made him sometimes unpopular in high quarters, but only for a time. A few months after becoming Director-General, he, in the Legislative Council, boldly declared his policy as regards the I.M.S., the improvements he considered necessary to carry out in it, and the way in which these improvements should be introduced. That was the occasion on which he said that the conditions of the I.M.S. had become intolerable. Many of the suggestions he then made have since been given effect to. It was largely due to Sir William Rice Edwards that the I.M.S. owes the concession that its Director-General may now see the Viceroy personally on technical matters, a privilege which has likewise been extended to all Inspectors-General of Civil Hospitals, and has been of the greatest use to the medical services in India. Sir William Rice Edwards was a reliable friend and an excellent companion."

Medical News.

UNIVERSITY OF CAMBRIDGE.—At examinations held recently the following candidates were successful :—

DIPLOMA IN PUBLIC HEALTH.

Lachhman Singh Ahluwalia, Gilbert A. Back, William Bird, John McPhail Campbell, Jhangi Ram Chaudhri and Herbert L. Cronk (distinguished in the Application of Sanitary Science), Robert Cunningham, Mary A. Grant, Alice J. Gray, Susan M. S. Jamieson, Henry D. Kelf, John McWilliam McDonald, Wazir Chand Mathur, Archibald C. Munro (distinguished in the Principles of Hygiene, in Bacteriology, and in the Application of Sanitary Science), Cuthbert E. R. Norman, Alexander C. Paterson, Rajapuram Nellaveran Raja, Abdel Magid Ramzy, Gladys H. Randall (distinguished in the Principles of Hygiene), Abd El-Hamid Sadek, Manuel J. Saldanha, Ardeshir Merwanji Seervai, Florence G. Sherry, Isobel M. Smith, Katherine C. Spence, Bertram Suggit, Nora I. Wattie, Robert Weaver, Alan D. Whitelaw, and Catherine B. Wilson.

DIPLOMA IN HYGIENE.

Ahmed Mohamed Kamal (distinguished in the Application of Sanitary Science) and Mohamed El Sebaiy.

UNIVERSITY OF OXFORD : *Hospital Scholarships.*—The following members of the Medical School have been elected to scholarships at the undermentioned hospitals :—Guy's Hospital : War Memorial Scholarships, £80, D. Lurie, Lincoln College ; University Students Open Scholarship, £80, W. D. B. Read, Magdalen College. London Hospital : Second University Scholarship, V. H. Brink, Hertford College. King's College Hospital : Burney Yeo Scholarships, J. W. de W. G. Thornton, Magdalen College, and J. A. Eyres, Lincoln College. St. Mary's Hospital : University Scholarships, £200, R. B. Bourdillon, University College, and P .C. Mallam, Queen's College. St. George's Hospital : University Scholarship, H. A. Byworth, Oriel College. Westminster Hospital : University Scholarship, £80, S. Segal, Jesus College.

UNIVERSITY OF LONDON.—A course of four lectures on the Treatment of Injuries of the Long Bones produced by Accident or Disease, will be given at Guy's Hospital Medical School by Prof. E. W. Hey Groves, at 5.30 P.M., on Nov. 8th, 9th, 12th, and 13th. At the first lecture the chair will be taken by Mr. H. J. Waring.

A Gift for Otology.—The University of London have accepted a gift of £10,000 from Mr. Geoffrey E. Duveen to found a chair of otology, and the donor intends to allocate a further £15,000 to University College Hospital for the provision of modern treatment of the deaf. The double gift is made in memory of the donor's father, Mr. Henry J. Duveen, one of the founders of the art firm of Duveen Bros., of London, Paris, and New York. Mr. Duveen the elder brought together some of the most famous art collections in America and the French honoured his reputation by appointing him Chevalier of the Legion of Honour.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—A quarterly Council meeting was held on Oct. 18th, with Sir John Bland-Sutton in the chair. A vote of thanks was passed to Mrs. Elliott, widow of Dr. John Elliott, of Chester, for presenting a number of skulls and skeletons from the cemetery of the Roman Occupation period exposed during the extension of the Chester Infirmary, and to Prof. Derry, of Cairo, for presenting a number of interesting and valuable specimens brought over by him from Egypt.—On behalf of the Committee on the Annual Report of the Council a draft copy of the report to be presented to the Fellows and Members at the annual meeting on Nov. 15th was submitted, and the report was approved and adopted.—Mr. Herbert Tilley and Mr. Arthur H. Cheatle were elected examiners for Part I. of the examination for the Diploma in Laryngology and Otology. Mr. H. James Marriage was elected examiner for Part II. of the examination for the same diploma.—The President reported that the Sir Gilbert Blane medal had been awarded to Surg.-Lieut.-Comdr. Julian Lionel Priston, M.B., R.N.—The President reported the receipt of a portrait by Troubtzkoy of the late Sir William MacCormac, President of the College from 1896 to 1900, bequeathed to the College by Lady MacCormac.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At the meeting of the College held on Oct. 17th Sir Harold J. Stiles, LL.D., was elected President for the ensuing year, Sir David Wallace, C.M.G., Vice-President, and Mr. Alexander Miles, F.R.C.S.E., Secretary and Treasurer.

Fellowship Examination.—The following candidates, who passed the requisite examinations between July 9th and 13th, were admitted Fellows :—

Sankaranainarkoil Chidambaranatha Alagappan, Walter M. Ash, Frederick W. W. Baillie, Edgar B. Barnes, Harold C. Brayshaw, Reginald C. Clifford, Bernard T. Cullen, Manikkam Durairaj David, Alexander Galletly, Leslie J. Middleton, Douglas A. Mitchell, Norman A. M. Petersen, and Herbert B. Scott.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Royal Faculty of Physicians and Surgeons of Glasgow.—At examinations recently held the following candidates were successful :—

Third Examination.

David Lumsden, George McCracken, Ernest G. Douglas, Cassaly Ismail, Philip Henry, Byerley C. F. Leembruggen, Lewis Mackenzie, William W. Crawford, Jessie R. Bruce, Kristian Skulberg, Arthur A. F. Shepherd, and John B. Hutchison.

Pathology.—Guthrie Russell, John A. Mains, Elizabeth C. Mudie, and Joseph W. McVicker.

Materia Medica.—John L. Dearberg, Robert J. Snodgrass, Alistair G. Cruikshank, Arthur G. Farquharson, Henry B. Martin, Thomas D. Gould, William Jackson, William Allan, and William E. Williams.

Final Examination.

Joseph W. Ridley, James Ryan, Dunstan D. S. Outschoorn, James S. Allan, Soo Hock Tan, Arthur H. Stephenson, Samuel L. Navaratnam, Robert G. Melrose, Joseph R. Whitaker, Carl F. Birkenstock, Alexander B. Williamson, Don Swithin Merl Emmanuel Perera, Phyllis M. Walker, Alexander Ross, Charles M. Hinds, Andrew Bury, Charles L. S. Ferdinands, Alexander L. Tinto, Alexander Gillies, Hieronymus Hoffmann, George A. P. McConey, William R. Robertson, John G. Thomas, Ronald M. MacKinnon, and Herbert E. Schokman.

Medicine.—Richard F. Kerr, Akinlawon Adefolu, Velayatham Pillai Thiyagaraja, Arthur W. H. Noble, Pattel Shankerlal Hathibhai Masters, James Kirkness, and Jitendra Nath Dey.

Surgery.—Arnold Raff and Vethavanam Vaithialingham.

Midwifery.—Arnold Raff, Annie H. Sutherland, Akinlawon Adefolu, Velayatham Pillai Thiyagaraja, George C. Philips, Vethavanam Vaithialingham, Sinnatamby Thambipillai, Clement A. Barrow, Joseph McAuley, Wilhelmina C. Storrie, Elizabeth Clark, and William Melrose.

Medical Jurisprudence.—William T. Baker, Tom G. S. Harkness, Joseph B. Stromier, Irma E. L. Mackenzie, James Houston, James K. Hunter, Mohammed Mustafa El-Makkawi, James H. MacAlpine, John Harkness, Nashid Tadros Yusif, Donald L. Crawford, Bruce F. Home, and Henry A. Newton.

The following candidates having passed the requisite examinations have been admitted Diplomates in Public Health :—

William S. Macdonald, Elizabeth N. Thompson, Alexander R. Lester, James F. Seale, William Campbell, Harvey Nichol, Robert G. Shaw, Dorothea I. Baird, Peter Hutchison, Katharine J. Guthrie, James S. McLean Gray, James L. Halliday, Margaret A. Galbraith, William McKie, Peggy L. Mitchell, John G. Gill, Kenneth A. Macrae, Frank D. M. Beaton, Katrine Dunn, David T. Richardson, Catherine Hill, Helen Campbell, George W. Murray, Charles M. Smith, and Robert Wiggins.

Royal College of Physicians of Ireland.—At the annual stated meeting of the President and Fellows of the College, held on Oct. 18th, the following officers were elected for the coming year :—

President : Dr. Michael F. Cox. Vice-President : Sir William J. Thompson. Censors : Sir W. J. Thompson, Dr. W. J. Dargan, Dr. J. Speares, Dr. R. E. Tottenham. Additional Examiners to take the place of an absent Censor or Examiner : Medicine, Dr. G. Nesbitt ; Midwifery, Dr. J. S. Sheill ; Medical Jurisprudence and Hygiene, Dr. S. T. Gordon. Examiners for the Licence to practise Midwifery : Dr. Gibbon FitzGibbon and Dr. MacLaverty. Supplemental Examiners under the Conjoint Scheme : Biology, Dr. G. Nesbitt ; Chemistry, Dr. H. C. Earl ; Physics, Dr. W. A. Winter ; Pharmacy, Materia Medica, and Therapeutics, Dr. F. X. Callaghan ; Physiology, Dr. Harold Pringle ; Anatomy, Dr. H. C. Earl ; Pathology, Dr. J. T. Wigham ; Medicine, Dr. F. C. Purser. Examiners for the Conjoint Diploma in Public Health : Hygiene, Dr. H. Bewley ; Bacteriology, Dr. H. C. Earl ; Sanitary Law and Vital Statistics, Sir W. J. Thompson ; Meteorology, Sir John Moore. Examiners for the Conjoint Preliminary Examination : Languages, Mr. E. H. Alton, F.T.C.D. ; Irish, Mr. E. J. Gwynn, F.T.C.D. Examiners for the Membership : Practice of Medicine, Dr. A. R. Parsons and Dr. J. Speares ; Clinical Medicine, Dr. W. J. Dargan and Dr. J. A. Matson ; Pathology, &c., Dr. H. C. Earl and Dr. A. C. O'Sullivan ; Obstetrics and Gynæcology, Dr. T. H. Wilson and Dr. Bethel Solomons. Representative on the General Medical Council : Sir John Moore. Representatives on the Committee of Management : Dr. Walter Smith, Sir John Moore, and Dr. T. Percy C. Kirkpatrick. Treasurer : Dr. Henry Bewley. Registrar : Dr. T. Percy C. Kirkpatrick. Librarian : Mr. R. Phelps. Law Agent : Messrs, Stephen Gordon, Son, and Wilson. Agents to the Trust Estate of Sir Patrick Dun : Messrs. Townshend.

Edinburgh University Club of London.—The 200th dinner of the Club will be held at the Connaught Rooms, London, at 7.30 P.M., on Friday, Nov. 23rd. The chair will be taken by the Earl of Balfour, the president of the Club, and there will be a large gathering of members and their guests. The Club now numbers 600 members.

Fellowship of Medicine and Post-Graduate Medical Association.—The programme of special courses arranged for November covers a wide range of subjects, beginning with a fortnight's course in general medicine and surgery at the Royal Northern Hospital in conjunction with the Central London Ophthalmic Hospital, North-Eastern Fever Hospital, and the Royal Chest Hospital. Clinical demonstrations in the various departments will be given each day from 10.30 A.M., concluding with a lecture at 4.30 P.M. Also, beginning on Nov. 5th and continuing throughout the month, there will be a course in Gynæcology at the Chelsea Hospital for Women. Lectures will be given by members of the staff each day, preceded by demonstrations in the out-patient department or operations in the theatre. A month's course in psychological medicine has been arranged at the Maudsley Hospital, Denmark Hill, and will consist of lectures and demonstrations on the psychoneuroses, the practical aspect of mental deficiency, the pathology of mental diseases, clinical psychiatry, and crime and insanity. Also, at the London Lock Hospital (Dean-street and Harrow-road), a comprehensive course of lectures and clinical demonstrations on venereal diseases will be given from Nov. 5th to 29th. A lecture on some aspect of the subject will be given each day supplemented by clinical work in the wards and out-patient department. From Nov. 19th to Dec. 15th a practical course in ophthalmology will be given at the Royal Westminster Hospital. In addition to clinical instruction every afternoon from 2 P.M., a practical fundus class and specia demonstrations in medical ophthalmology and methods of examination will be given three times a week at 10 A.M Beginning on Monday next, Oct. 29th, a two weeks' course in dermatology will be given at the Hospital for Diseases of the Skin, Blackfriars, consisting of clinical instructions every afternoon from 2.30 with special demonstrations on selected cases. Further particulars and copies of the syllabus of any of the above courses will be forwarded on application to the Secretary to the Fellowship of Medicine, at 1, Wimpole street, W.

Royal College of Physicians of London.—The Bradshaw lecture will be delivered on Nov. 1st at 5 P.M., by Dr. John Hay, the subject being Angina Pectoris : Some Points in Prognosis. Dr. C. J. Singer will give the FitzPatrick lecture on the History of Anatomy on Nov. 6th and 8th.

The President of the Dermatological Section of the Royal Society of Medicine and Mrs. Graham Little held an evening reception on Oct. 16th to meet Dr. John Addison Fordyce, Professor of Dermatology, Columbia University and Bellevue Hospital Medical College, New York. Man distinguished guests were present. On Oct. 18th D Fordyce read a paper on the Treatment of Neuro-syphili before the Dermatological Section, which we publish on p. 932 of our present issue.

In reviewing last week a series of five admirabl but unrelated "Surgical Monographs" we protested strongl against the arbitrary action of the publisher in refusing t supply any one of the monographs separately. We now learn that at a meeting of the Library Committee of th Royal Society of Medicine it was resolved that the purchas of the monographs would be considered only when th publishers had withdrawn this restriction.

North-Western Tuberculosis Society. — Dr Leonard Hill, F.R.S., will deliver a lantern lecture, entitle Climate and the Treatment of Consumption, at th Tuberculosis Department, Joddrell-street, off Hardman street, Deansgate, Manchester, on Thursday, Nov. 1st, a 3 P.M. Medical practitioners interested in this subject ar invited to attend.

London Hospital Medical College.—The following awards have been made : "Price" University Scholarship in Human Anatomy and Physiology : H. L. Green Sidney Sussex College, Cambridge ; proxime accessit, V. F Brink, Hertford College, Oxford (awarded a second scholarship).

Society of Medical Officers of Health.—Th annual dinner was held on Oct. 19th at the Hotel Ceci London, Dr. T. W. Naylor Barlow, O.B.E., the president of the Society, occupying the chair. A large and representativ company was present, the guests including Sir William Joynson-Hicks, the Minister of Health, Sir George Newma and Sir Arthur Robinson, of the Ministry of Health, M Justice Swift, Sir Humphry Rolleston, Lord Riddell, S Dawson Williams, Dr. Alfred Cox, and Sir Squire Sprigge. Th "Prosperity of the Society" was proposed by the Minist of Health, who said that his new official position would brin him into intimate contact with the Society, and that he wa quite sure that all their members would join with him i a campaign which he looked forward to fighting during th next few years, if he was spared to remain in office, for th better distribution of the surplus urban populations in th country districts. He would like, he said, with th coöperation of local authorities, to drive great arteri through overcrowded districts into unoccupied region forming giant thoroughfares across country districts, when the people, now crowded in slumdom, would follow the new routes into health and healthy occupation. Dr. Barlow, whose reply was a happy admixture of the serious and the humorous, said that he claimed for the medical officers of health the position of being the outposts of the Ministry of Health, and he assured the Minister that the Society would place at his disposal all the knowledge and experience which they had acquired and were acquiring. The toast of "The Guests" was proposed by Colonel F. E. Fremantle, M.P., and was responded to by Lord Riddell and Sir Squire Sprigge, "The Health of the Chairman" being happily dealt with by Sir Benjamin Johnson, High Sheriff of Lancashire. The proceedings during the evening were interspersed by songs from Miss Victoria Barton and Mr. John Saville, accompanied at the piano by Miss Iris Tregoning. Mr. Tom Clare also entertained at the piano.

BRITISH DENTISTS' HOSPITAL.—The annual general meeting will be held to-day, Saturday, Oct. 27th, at 3.30 P.M., with Sir Harry Baldwin, the president, in the chair.

SMALL-POX IN ENGLAND AND WALES.—During the week ended Oct. 13th, 33 new cases of small-pox were brought to the notice of the following sanitary authorities: Berks 3 (Wokingham); Derbyshire 1 (Chesterfield); Gloucestershire 20 (Gloucester 16, "including one case notified as chicken-pox but rediagnosed as small-pox," East Dean R.D. 3, Gloucester R.D. 1); Northumberland 1 (Tynemouth); Notts 5 (Kirkby-in-Ashfield 4, Mansfield 1) Yorks North Riding 2 (Middlesbrough 1, Flaxton R.D. 1); Yorks West Riding 1 (Adwick-le-Street).

INSTITUTE OF HYGIENE.—A lecture will be delivered on Oct. 30th by Dr. W. G. Savage on the Balance of Diet, at 3.30 P.M. On Nov. 6th Dr. James Fenton will speak on Preservatives and Adulterants in Foods; and on Nov. 13th Dr. A. Middleton Hewat will discuss Pure Food Supplies. On Nov. 20th Sir Kenneth Goadby will speak on Diet and Disease; and on Nov. 27th Mr. Joseph E. Adams will give an address on Habits, Diet and Malignant Disease. These lectures are part of a series on Food and Diet, which are being delivered under the auspices of the Institute of Hygiene, 33–34, Devonshire-street, London, W. 1, at 3.30 P.M. on Tuesdays.

CHADWICK PUBLIC LECTURES.—The following lectures will take place during October, November, and December, 1923. On Oct. 29th, at 5.15 P.M., at the house of the Medical Society of London, Chandos-street, Cavendish-square, with Sir Malcolm Morris presiding, Dr. C. Killick Millard will lecture on the Disposal of the Dead. On Nov. 9th, 16th, and 23rd, at 8 P.M., at the house of the Royal Society of Arts, John-street, Adelphi, Major Harry Barnes will give three lectures on Hygiene and Architecture. At the first lecture on Health and Town-planning, Mr. W. E. Riley will preside. At the second on Health and the Building, Mr. J. Slater will preside, and at the third, on Health and the Hospital, Sir William J. Collins will preside. On Dec. 3rd, at 8 P.M., at the Goldsmiths' College Lecture Hall, New Cross, Dr. A. K. Chalmers will lecture on Housing Standards—How they can be Raised, Sir William J. Collins again presiding, and on Dec. 5th, at 5.30 P.M., Dr. Chalmers will lecture on the same subject at Kensington Town Hall, with Sir James Crichton-Browne in the chair. Two lectures will be given in November at Bristol University, the Vice-Chancellor presiding. On Nov. 22nd and 29th, at 5.30 P.M., Dr. W. M. Willoughby will lecture on the Theory and Reasonable Practice in the Disinfection and Disinfecting of Ships. The first lecture will be devoted to Disinfection in Diseases due to Bacteria, and the Ultra-microscopic Viruses, and the second to Disinfection and Disinfecting in Insect and Rat-borne Diseases. Admission is free to all these lectures. Further particulars may be obtained from the Secretary, at the offices of the Chadwick Trust, 13, Great George-street, Westminster, London, S.W. 1.

MANCHESTER LOCAL VOLUNTARY HOSPITALS COMMITTEE.—This Committee has issued a special report dealing with the 17 local hospitals and their maintenance on the voluntary system, and also on their local work and funds. The Committee representative was appointed in 1921, and has on it representatives nominated by the Voluntary Hospitals Commission, the City Council, the hospitals, and two medical representatives. Amongst the other good offices of the Committee it advised the Voluntary Hospital Commission as to the distribution of £17,485 to hospitals in the local area, and was instrumental in arranging a scheme for raising money from employers and employees for the Convalescent Homes Fund. The statistics show that for 1922 the total ordinary income of the 17 hospitals was £231,852 and the expenditure £281,276, thus giving a deficit for the year of £49,424. Of the total income only 16 per cent., or £36,969, was subscribed by patients; £38,997 was received from local authorities and approved societies in respect of patients or for the use of beds; £51,476 was derived as income from invested property, and the balance, £104,400, was met from various voluntary sources. For maintenance the ordinary expenditure was £281,276, leaving a deficit for the year of £49,424. These figures do not include extraordinary income—legacies, grants from Voluntary Hospitals Commission—but if these be added to ordinary income, there still remained a deficit for the year of £15,847. The Committee recommend that free legacies should be invested in order to help provide a regular source of income, but many hospitals, owing to their urgent financial needs, have been unable to follow this advice, and such legacies had to be employed for current expenditure. The statistics as to attendance show that the Manchester and Salford Hospitals, besides providing for the local needs of the city and borough, are largely made use of by patients from the adjoining towns and from areas much further afield —e.g., from Yorkshire, Cumberland, Westmorland, Derbyshire, Cheshire, and Wales. The estimated cost of in-patients was £224,398, and the average cost of bed occupied was £121 3*s*. 9*d*. and of each in-patient £8 3*s*. 6*d*.; the average payment by each patient was 15*s*. 11*d*., and the amount to be provided for each in-patient from voluntary sources was £7 7*s*. 7*d*. and the amount provided from voluntary sources for each out-patient 5*s*. 9*d*.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear it if reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY, Burlington House, W.
THURSDAY, Nov. 1st.—4.30 P.M.
Papers to be read: E. G. T. Liddell and Sir Charles Sherrington, P.R.S.: A Comparison between Certain Features of the Spinal Flexor Reflex and of the Decerebrate Extensor Reflex respectively. J. Barcroft and H. Barcroft: The Blood Pigment of Arenicola. T. Deighton: The Basal Metabolism of a Growing Pig. (Communicated by Prof. T. B. Wood.)

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Tuesday, Oct. 30th.

Social Evening.

The first Social Evening of the Session will be held on Tuesday, Oct. 30th, at 8.30 P.M.

Fellows, Members of Sections, Associates and their friends will be received by the President, Sir William Hale-White, and Lady Hale-White, at 8.30 P.M.

The Society's Gold Medal will be presented to Prof. Gowland Hopkins, F.R.S., Professor of Biochemistry, University of Cambridge, who will give, at 9 P.M., a short Address entitled "Stimulants of Growth."

LIBRARY:
On this evening the principal Reading Room will be closed at 5 P.M., but readers will be accommodated in other rooms.

Thursday, Nov. 1st.

OBSTETRICS AND GYNÆCOLOGY: at 8 P.M.
Specimens:
Mr. A. C. Palmer: (1) Strangulated Uterine Hernia of Small Intestine. (2) Congenital Cavernous Hæmangioma of Liver.
Short Communication:
Dr. Alfred B. Danby: Three cases of Pregnancy with Extravasation of Blood in Association with Albuminuria.
Paper:
Dr. Moreland McCrea and Mr. Victor Bonney: The Relation between Certain Disorders of the Female Pelvic Organs and Symptoms ordinarily considered the Province of the Physician.

UNIVERSITY OF LONDON SEMON LECTURE, in the Barnes Hall, at 5 P.M.
Dr. A. Logan Turner: The Advancement of Laryngology: a Plea for Adequate Training and Closer Cöoperative Action.

Friday, Nov. 2nd.

LARYNGOLOGY: at 4.45 P.M. (Cases at 4 P.M.)
Cases and Specimens will be shown by Sir James Dundas-Grant, Mr. A. J. Hutchison, Dr. Macleod, Mr. J. F. O'Malley, Mr. J. S. Fraser, and others.

ANÆSTHETICS: at 8.30 P.M.
Paper:
Dr. Henry Featherstone: A Critical Report on 100 Cases of Spinal Analgesia with Tropacocaine.

Saturday, Nov. 3rd.

OTOLOGY: at 10 A.M.
Demonstration:
Mr. J. S. Fraser: Demonstration of Lantern Slides showing Changes in Inner Ear in a Congenitally Deaf Dog.

Cases:

Sir James Dundas-Grant will show a case illustrating Digital Compression of Vertebral Arteries for Pulsating Tinnitus.

Cases will also be shown by Mr. T. B. Layton, Dr. A. R. Friel, and others.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

Monday, Oct. 29th.—10 a.m., Mr. Maingot: Surgical Pathology. 12 noon, Mr. Simmonds: Applied Anatomy. 3 p.m., Mr. Simson: Diseases of Women.

Tuesday.—10.30 a.m., Dr. Paterson: Medical Wards. 12 noon, Dr. Burrell: Chest Cases. 2.30 p.m., Mr. Tyrrell Gray: Surgical Wards.

Wednesday.—10 a.m., Dr. Saunders: Medical Diseases of Children. 12.15 p.m., Dr. Burnford: Medical Pathology. 3 p.m., Dr. Pernet: Skin Dept.

Thursday, Nov. 1st.—10 a.m., Dr. Grainger Stewart: Neurological Dept. 12 noon, Mr. Simmonds: Demonstration of Fractures. 2 p.m., Mr. MacDonald: Genito-Urinary Dept.

Friday.—10 a.m., Dr. Drummond Robinson: Gynæcological Operations. 2 p.m., Mr. Banks-Davis: Nose, Throat, and Ear Dept. 2 p.m., Mr. Sinclair: Surgical Out-patients.

Saturday.—9.30 a.m., Dr. Burnford: Bacterial Therapy. 10 a.m., Dr. Saunders: Medical Diseases of Children. 10 a.m., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily, 10 a.m. to 6 p.m., Saturdays, 10 a.m. to 1 p.m., In-patients, Out-patients, Operations, Special Departments.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: October–November, 1923.

Clinical Lectures and Demonstrations.

Monday, Oct. 29th.—2 p.m., Out-patient Clinic: Dr. Hinds Howell. 3.30 p.m., Disorders of Intellectual Expression: Dr. Kinnier Wilson.

Tuesday, Oct. 30th.—2 p.m., Out-patient Clinic: Dr. Grainger Stewart. 3.30 p.m., Muscular Atrophies: Dr. Adie.

Thursday, Nov. 1st.—2 p.m., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 p.m., Cerebral Tumours: Dr. Gordon Holmes.

Friday, Nov. 2nd.—2 p.m., Out-patient Clinic: Dr. Gordon Holmes. 3.30 p.m., Cerebral Abscess: Mr. Sydney Scott.

Course of Lectures and Demonstrations on Neuro-Pathology.

Monday, Oct. 29th.—12 noon, Paths of Infection of Central Nervous System: Dr. J. Godwin Greenfield.

A Course of Lectures on the Anatomy and Physiology of the Nervous System commenced on Oct. 16th.

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 a.m., or at such other times as may be announced.

The fee for the Course, including Pathology, is £5 5*s.* The fee for the Anatomy and Physiology Lectures is £3 3*s.* If taken in conjunction with the Clinical and Pathological Courses, an inclusive fee of £7 7*s.* will be charged. Any part of the Course may be taken separately. Special arrangements will be made for those unable to take the whole Course. Fees should be paid to the Secretary of the Hospital at the office on entering for the Course.

C. M. Hinds Howell, Dean of Medical School.

ST. JOHN'S HOSPITAL, Leicester-square, W.C.

Tuesday, Oct. 30th.—5 p.m., Dr. S. E. Dore: Alopecia.

Thursday, Nov. 1st.—5 p.m., Dr. J. M. H. MacLeod: Elementary Pathology of the Skin.

HOSPITAL FOR SICK CHILDREN, Gt. Ormond-st., W.C.

Thursday, Nov. 1st.—4 p.m., Dr. Thursfield: Rickets.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.

Wednesday, Oct. 31st.—4 p.m., Major H. G. Anderson: Air Accidents.

LIVERPOOL UNIVERSITY CLINICAL SCHOOL.

(At 3.30 p.m. each day.)

Monday, Oct 29th.—(At the Children's Hospital.) Mr. McMurray: Hip Conditions in the Child.

Tuesday.—(At the Southern Hospital.) Mr. Newbolt: Operations on the Elderly.

Wednesday.—(At the Northern Hospital.) Mr. McMurray: Derangements of the Knee-Joints.

Thursday, Nov. 1st.—(At the Stanley Hospital.) Dr. Wadsworth: The Significance of the Heart Sounds.

Friday.—(At the Royal Infirmary.) Mr. Litler Jones: Surgical Cases.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE CLINIC.

Tuesday, Oct. 30th.—4.15 p.m., Mr. W. H. Hay: Tumours and Ulcers of the Mouth.

Friday, Nov. 2nd.—4.15 p.m., Dr. T. H. Oliver: Physiology and Pathology of Diabetes Mellitus.

SALFORD ROYAL HOSPITAL.

(Special Course on Surgical Tuberculosis.)

Thursday, Nov. 1st.—4.30 p.m., Mr. G. Jefferson: Tuberculosis of the Lymphatic Glands.

UNIVERSITY OF BRISTOL POST-GRADUATE DEMONSTRATIONS.

Wednesday, Oct. 31st.—(At Swindon), Prof. F. H. Edgeworth: *Bacillus Coli* Infections of the Urinary Tract.

Appointments.

Paddington Green Children's Hospital: Leys, D., M.B., B.Ch. Oxf., House Physician; Hyslop, W. M., M.B., Ch.B. Edin., House Surgeon.

Royal Infirmary, Edinburgh: Osborne, D. C., M.B., Ch.B. Edin.; Martin, K. A. F., M.B., Ch.B. Edin.; Barlow, P., M.B., Ch.B. Edin.; Butler, A. J. H., M.B., Ch.B. Edin.; Walker, E. R. C., L.R.C.P. Edin.; Anderson, H. P., M.B., Ch.B. Edin.; Watson, W. N. Boog, M.B., Ch.B. Edin.; Yooll, M. A. G., M.B., Ch.B. Edin., Resident House Physicians. Munro, H., M.B., Ch.B. Edin.; McClure, J. H.; Morrison, W., M.B., Ch.B. Edin.; Evers, J., L.R.C.P. Edin.; Cameron, D., M.B., Ch.B. Edin.; Hetherington, W., M.B., Ch.B. Edin.; Dinwiddie, J. L. N., M.B., Ch.B. Edin.; Caird, J. C., M.B., Ch.B. Edin.; Kennedy, C. D., M.B., Ch.B. Edin.; Robertson, I. M., M.B., Ch.B. Edin.; Cowan, J. M., M.B., Ch.B. Edin.; Thwaites, H. V., M.B., Ch.B. Edin.; Wilson W. L., M.B., Ch.B. Edin., Resident House Surgeons.

Vacancies.

For further information refer to the advertisement columns.

Bath Royal United Hospital.—Asst. H.S. £150.
Blackpool, Victoria Hospital.—Asst. H.S.
Bolton Education Committee.—Ophth. S. 3 guineas per session.
Bootle Borough Hospital.—Jun. Res. M.O. £125.
Bristol General Hospital.—Two H.P.'s., H.S., &c. Each £125.
Cambridge, Addenbrooke's Hospital.—H.S. £130.
Charing Cross Hospital Medical School.—Chemist to Bio-chemical Dept. £500.
City of London Hospital for Diseases of the Heart, Victoria Park, E.—H.P. £125.
Dundee Royal Infirmary.—Hon. Asst. Vist. Phys.
Eastern Dispensary, Leman-street, E.—P.
Hereford County and City Mental Hospital.—Second Asst. M.O. £350.
Hospital for Sick Children, Great Ormond-street, W.C.—Med. Reg. and Pathologist. £300.
Islington Dispensary, 303, *Upper-street, N.*—Sen. and Asst. R.M.O.'s. £300 and £220 respectively.
Leeds Public Dispensary.—Sen. Res. M.O. £200.
Lincoln County Hospital.—Jun. H.S. £150.
Liverpool Eye and Ear Infirmary.—H.S. £100.
London County Mental Hospital Service.—Seventh Asst. M.O. £432.
London Jewish Hospital, Stepney Green, E.—Res. M.O. and Jun. Res. M.O. £150 and £100 respectively.
Nottingham General Dispensary.—Two Res. Surgs. Each £250.
Prince of Wales's General Hospital, Tottenham, N.—Hon. Asst. S. to Ear, Nose, and Throat Dept.
St. George's Hospital Convalescent Branch, Copse Hill, Wimbledon.—R.M.O. £300.
St. Mary's Hospital, Paddington.—Two Bacteriologists. £400.
St. Mary's Hospital for Women and Children, Plaistow, E.—Asst. Res. M.O. £130.
St. Peter's Hospital, Henrietta-street, W.C.—Asst. S.
Salisbury Municipality, Rhodesia.—M.O.H. £600.
Sheffield Royal Infirmary.—Ophth. H.S. £100. H.P. £100.
Southampton County Borough.—Second School Dentist. £450.
Torquay, Torbay Hospital.—H.S. £200.
West London Hospital, Hammersmith-road, W.—Hon. Asst. S. to Throat, Nose and Ear Dept.

Births, Marriages, and Deaths.

BIRTHS.

Boys.—On Oct. 19th, at Brookside, Woodhall Spa, the wife of Leonard Boys, M.B., of a son.

Jobson.—On Oct. 20th, at The Cottage, Kingsdown, near Deal, the wife of J. Stanley Jobson, M.B., F.R.C.S., of Weymouth-street, W., of a son.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Presentation to a Medical Man.—On the evening of Oct. 20th, a large gathering of members of the medical profession and a few friends assembled at dinner at the Royal Albion Hotel, Brighton, to bid an official farewell to Dr. Edmund Hobhouse, who recently gave up his residence at Hove on his appointment as a member of the Lord Chancellor's Pensions Appeals Tribunal. Dr. W. Broadbent presided and Dr. L. A. Parry presented an address. Dr. Henry Gervis proposed "The Health of Dr. Hobhouse," and was supported by Dr. Sanderson. Dr. Hobhouse, in response, said that he should look back on his time in Brighton with great happiness. The profession in Brighton was a very contented one, and this was largely due to the goodwill of its members and the fact that the two bodies in Brighton—the British Medical Association and the Medico-Chirurgical Society—had always been in harmony one with another.

Notes, Comments, and Abstracts.

THE POSITION OF THE NATIONAL INSURANCE COMMITTEES.

Summary of the Presidential Address delivered to the Annual Meeting of the National Association of Insurance Committees on Oct. 19th, 1923,

BY SIR WILLIAM GLYN-JONES.

Sir William Glyn-Jones invited the delegates to consider how far after 12 years' working the promises of the Insurance Act had materialised in fulfilment, and particularly whether insurance committees were performing the functions allotted to them by Parliament, and whether the duties at present performed by the insurance committees justify their continuance. In so far as the Insurance Acts provided direct personal and individual benefits such as medical treatment, maternity benefit, and sick pay, he asserted that the contracts had been in the main fulfilled. Insured patients were better served and doctors better paid than they were, and though neither should be fully satisfied, the improvement in service and pay as compared with the situation prior to 1911 would in itself justify the Insurance Act. In 1922 insured persons were paid over 8 million pounds in sickness benefit, and more than 3¼ million pounds in disablement benefit; whilst it is estimated that over 6 million persons received medical treatment, involving 44 million attendances. Maternity benefit had proved an undoubted boon. Sanatorium benefit was no longer a part of the scheme, but the special provisions relating to tuberculosis, incomplete as they were, enabled a substantial advance to be made in the prevention and treatment of that great scourge.

Successful Working of the Act.

Sir George Newman, chief medical officer of health of the Ministry of Health, had reported that "great gains have been made in the health of the nation, and the death-rate is declining." To the working of the Insurance Act must be attributed a due share of the credit. Whilst insurance committees had played a great part in the work thus accomplished, they had not been given the responsibilities nor exercised the powers even in those matters which Parliament in the Insurance Act entrusted to them. The Act gave to insurance committees the administration of medical benefit, and of all additional benefits of the nature of medical benefit. They had to make arrangements with medical practitioners, and bargain with the approved societies having members in their areas as to the amount to be paid in respect of medical benefit and its cost of administration. All these negotiations had been conducted by the Ministry; insurance committees and societies were told what the arrangements made were and had to abide by them. It was admitted that collective national bargaining in these cases was inevitable, but the fact remained that the powers Parliament entrusted to committees were not and never had been performed by them. The conditions under which sanatorium benefit was for a time administered by insurance committees were always extremely unsatisfactory, necessarily so at the commencement of such a scheme. In spite of the limitation imposed by regulations, by want of funds, and the clashing of their powers and duties with those possessed by other local authorities, these committees performed a great work, which involved substantial responsibility for policy, and gave to the members scope for real capacity as administrators. The confusion and anomalies for which the committees were not responsible led to an amendment of the Act, and sanatorium benefit had ceased to exist. Since May, 1921, the administration of sanatorium benefit had not been a duty of insurance committees.

The temporary scheme for the administration of the benefits for deposit contributors was to last until January, 1915, a date now extended to December, 1924. No one was satisfied with this part of the scheme, and insurance committees were not proud of what they do or could not do for deposit contributors. Certain additional benefits of the nature of medical benefit (dental and optical treatment, hospital or convalescent home treatment, provision of appliances) had been provided for a portion of the insured persons. The popularity of these additional benefits had led to several suggestions for extension to include massage, radiant heat and electrical treatment, specialist treatment generally, brine baths, and laboratory facilities. The benefits provided had been administered by approved societies notwithstanding that the Act imposed the duty upon insurance committees. No additional benefits had been administered by insurance committees.

Powers Vested in the Insurance Committees.

The President then went on to emphasise the fact that the Government in promoting the National Insurance Bill of 1911 urged in its favour not only its insurance features and the provision made for the treatment of disease, but emphasised the provisions in the Bill for reducing sickness and disablement by removing their preventable causes.

An authority had made the following remarks immediately after the Act was passed:

> "The National Insurance Act will compel public attention in a manner not previously realised to the cost of the nation, not only in human lives, but in money, of bad housing, wretched conditions of employment, defective water-supply, and the like. . . . Local authorities are at times slow to effect improvements, which frequently mean a large expenditure of public money, often in an area which has already borrowed largely for municipal undertakings. But that this remissness has an appalling effect on the sick-rate of the inhabitants cannot be denied. There has accordingly been inserted in the Act a section (Sec. 63) empowering Approved Societies and Insurance Committees to demand inquiries into the causes of excessive sickness in the areas for which they are administering the Act."

Mr. Lloyd George, in the Second Reading debate (May 4th, 1911) said:

> "There will be a further power. If a county health committee are anxious to spend more money than they have funds at their disposal upon either the medical side or the sanatoria side, the county councils have power to agree to sanction further expenditure, provided the Treasury also agree. One-half the additional expenditure will come out of the rates, and the other half out of the Treasury. There are one or two other functions, to which I attach great importance, which the county health committees will have to discharge. They will have to consider generally the needs of the county and borough with regard to all questions of public health, and to make such reports and recommendations in regard thereto as they may deem fit. I shall point out later on that they have power beyond that of merely making reports and recommendations. . . . They will have power also to make provision for the giving of lectures and the publication of information on questions relating to health. . . . What we propose is that the county health committees shall have power to go to the Local Government Board whenever there is excessive sickness coming on the funds of the society, and apply for an inquiry into the cause of that sickness. Wherever the Commissioners of the Local Government Board find that it is due to neglect by the authority to discharge functions imposed by an Act of Parliament for the housing of the people, or for improved sanitation, they shall have the power of imposing that excess, not on the societies, who are not at fault, but upon the local authorities who are at fault. That will be a much more effective check than the old obsolete form of mandamus."

Lord Haldane, as spokesman for the Government in the Second Reading debate in the Lords, said:

> "We hope to get a committee that will settle the multitude of questions which will arise and which will vary from locality to locality, questions with which the Insurance Commissioners could not themselves adequately deal. The functions of the local insurance committees will be to report on health. That is the great thing. They will furnish statistics not only about abnormal but about normal conditions, such as we do not possess at the present time, and this ought to be of great value in combating disease."

Great promises were thus held out of the improvement in the health of the community to result from the passing of the Bill.

The executive of the association had expressed the opinion that whatever might be said about the working of this scheme in the direction of insurance and treatment, the other promises had not been fulfilled. Again, referring to the special health powers of the local committees, Mr. Lloyd George in the Committee stage said:

> "There is no proposal here to interfere with local authorities in any way, except that which is already enshrined, or, I think, embalmed is a better word, in Acts of Parliament, because most of them are mummies. They are not exercised, there is no life in them; they are pure dust, and they only have the form and features of life. There is none of the spirit and the soul in any of these powers. That is the reason why we propose that we should have some powers of this kind, in order not to interfere with local authorities, but I accept the word of the hon. Member (Mr. Harwood) to wind them up."

Sir William Glyn-Jones went on to say that he agreed that these words fairly described in 1911 the existing powers to which Mr. Lloyd George referred, but now, in 1923, the words equally applied, after 12 years, to the new powers and duties which as the result of that advocacy were conferred upon insurance committees by the Insurance Act. Whilst imputing neither motive nor intention, he asserted that insurance committees could be in no worse position had it been the deliberate policy to blanket them and by regulation to deprive them of all the power and responsibility given them by the Statute, and to leave them with such a modicum of routine duties as to justify their being put to as peaceful and painless an end as possible.

In conclusion, Sir William Glyn-Jones said: "I make all allowance for the war and its aftermath. Of course, the war inevitably gave to our work a great set-back, and it is a pity that the recuperative powers of social reform are not equal to those apparently possessed by football, racing, boxing, motoring, and other doubtless innocent but less profitable objects of expenditure of thought, time, and money, which appear to have regained their pre-war prosperity. That fact notwithstanding, we cannot be accused of unreasonable impatience if, five years after the Armistice, we ask the Government if and when insurance committees are to perform the duties for which they were created. The present position of insurance committees is one in which they cannot with self-respect continue. Does the Government think the work outlined for us should be abandoned, or that we are not the bodies to perform it? In either case let us and the country know. We cannot with self-respect continue to be parties to a sham fight against the evils which we were enrolled with such a flourish of trumpets and beating of drum to combat." The outgoing executive committee had directed attention to this aspect of the work of insurance committees, and he asked the conference to give a mandate to the executive they had just appointed to force the issue.

THE SILENT MILK-CAN.

MUCH of city or town life is only rendered possible by the development of a degree of insensitiveness to the uproar of civilisation about us. Even so, there remain individual sounds which never fail to torture some more sensitive ear. Schopenhauer, if we remember rightly, was infuriated by the cracking of cabmen's whips, and had not Carlyle a sound-proof study? At the present time many of those whose windows overlook crowded London thoroughfares must sometimes wish that a certain street vendor was, in the words of his own reiterated stave, "far, far away." And there must be a considerable daily aggregate of nervous irritation engendered in station hotels, waiting-rooms, and similar places, by the bump and clatter of milk-cans rolled along echoing platforms and hurled into or out of trains. To mitigate this last-named nuisance has been the aim of Mr. Arthur S. F. Robinson, of Barsham, Beccles. By means of rubber tyres set round the heads and bases, and rubber covers upon the handles, of milk-cans—or, as they are now commonly called, milk-churns—he has rendered the movement of these receptacles practically silent. Mr. Robinson has patented a new form of sealed churn, lighter than the type usually seen and heard, slightly shorter—since "splashing space" is not required—and fitted with silencing rubber. This churn will, it is claimed, benefit traders, railway companies, and the general public by eliminating not only the porter's nerve-shattering "tintamarre," but also the wastage of milk in transit, and the contamination which must take place when the lids of churns are not hermetically sealed.

A WARNING.

To the Editor of THE LANCET.

SIR,—A young man going under the name of Joyce or MacNamee is calling on Irish doctors, clergy, and laity in the Midlands to dispose of a book by S. MacManus, "The Story of the Irish Race." He gives a receipt for £1 2*s*., but the book does not arrive. He has, I understand, no connexion with the O'Molloy Publishing Co., Donegal, who market this book, and is at present in the Nottingham district.

I am, Sir, yours faithfully,

Nottingham. M. J. HORGAN, M.B.

MADEIRA, THE CANARY ISLANDS, AND THE AZORES.[1]

THE twelfth edition of Mr. A. Samler Brown's standard guide to Madeira, the Canary Islands, and the Azores contains 496 pages packed with information ranging from legends of lost Atlantis to the proper prices to pay for hiring a mule and the way to estimate the distance of the horizon. The medical interest of the volume is underlined by a Chapter for Invalids, which contains valuable advice to those who seek to regain their health in these resorts. Invalids in an advanced stage of illness are cautioned against visiting the islands alone, or are advised to place themselves under close medical supervision, since they "are too apt to imagine that the mere change of climate permits them to take liberties with their strength and stomach such as they would never dream of in Europe. Elated and excited by the charm of a nearly constant sunshine and of a temperature which permits them to be out at almost any hour of the day, they . . . presume on the increase of vigour common after a sea voyage, and, acting in an imprudent manner, frequently so accelerate the ravages of the disease from which they suffer, that they never recover, being subsequently cited as examples of the insalubrity or inefficiency of the climate." The variety of choice of climate and elevation in the different islands renders care necessary in the placing of a patient, otherwise, of course, this variety is a great addition to the value of the resorts. The chapter closes with notes on climatic diarrhœa and sea-sickness.

The guide contains new matter which includes meteorological statistics compiled at an elevation of 7000 to 7500 feet above sea-level, in the Cañadas (the crater valley lying around the Peak) of Teneriffe, where it is proposed to build a sanatorium above the Summer Trade Wind Zone. The volume is excellently illustrated with views and maps, and there are many statistical tables.

THE "PRANA" CARBON-DIOXIDE SNOW APPARATUS.

Sparklets Limited, Upper Edmonton, London, N. 18, have submitted for our inspection and trial a portable and satisfactory apparatus for making carbon snow pencils. It consists of a perforated metal cylinder about 3 inches long by 2 inches in diameter, to one end of which is affixed a vulcanite cone terminating in a tube closed at the end with a screw-cap. The other end of the cylinder is connected with a tube containing CO_2 under pressure. By means of a valve the CO_2 is allowed to flow into the cylinder at short intervals, and the snow formed in the cylinder is afterwards compressed in the exit tube by means of a vulcanite rod. The cap is then removed and the CO_2 pencil pushed through. The moulding tubes are made with both round and square sections. With a little practice the apparatus is easy to manipulate. The price is 3½ guineas, and the cost of refilling the CO_2 container is 2*s*. Other sizes are made for use in hospitals and surgeries.

NON-REGISTRABLE MEDICAL DEGREES ON PANEL LISTS.

To the Editor of THE LANCET.

SIR,—For the last nine years the degrees of British and colonial graduates holding foreign degrees have appeared in all the printed lists of practitioners who have consented to carry out the duties of the National Health Insurance. However, in March, 1923, without any notice, all these degrees were removed from the lists, because they were not at present on the Medical Register. As the general public attach great importance to an M.D. degree, this action of the Ministry of Health and of the London Insurance Committee has caused a great loss to these practitioners, by reason of the fact that any additional mark of academic distinction is duly taken into consideration by insured patients of all classes in choosing a doctor. In thus depriving these graduates of a necessary advertisement, someone connected with the Ministry of Health has been responsible for an exhibition of professional prejudice which may have far-reaching consequences. With regard to the graduates of the University of Brussels, we are now about 1000 strong in all parts of the British Empire, and I shall therefore be glad to hear from any graduate of this, or any other foreign university, with a view to combined action.

I am, Sir, yours faithfully,

ARTHUR HAYDON, M.D.,
Hon. Secretary, The Brussels Medical Graduates' Association.

41, Buckland-crescent, N.W. 3.

The Principles of
SYMPTOMATOLOGY:
AN INTRODUCTION TO A NEW OUTLOOK IN MEDICINE.

By Sir JAMES MACKENZIE, M.D. Edin.,
F.R.C.P. Lond., F.R.S.

(*From the St. Andrews Institute of Clinical Research.**)

In Three Parts.—Part I.

A survey of medical knowledge reveals defects in fields essential for the progress of medicine and for its intelligent practice. The chief of these defects is in the knowledge of what constitutes ill-health, and of the conditions that lead to death. The phenomena by which ill-health is recognised are the symptoms of disease.

The symptoms of disease are produced by organs whose functions are stimulated to unusual activity, or are depressed, or are suspended. Death is the result of the suspension of the activity of certain organs. The functional activity of organs is dependent on the cells peculiar to the organ and on nerves or other structures that regulate the functional activity. These parts can be represented by a reflex arc in which impulses taken up by a receptor are conveyed by afferent and efferent nerve fibres to the effector organ. The value of the principle of the reflex arc is dependent on the fact that symptoms are produced by disturbances of one or more of the elements of which the arc is composed. The recognition of this principle compels an analysis to find at what element of the arc any given disturbance takes place. The attempt to apply this principle to the interpretation of symptoms has revealed that the nature of the regulating process is not known for any of the organs. The chief reason for this is found to lie in the absence of knowledge of the afferent system of nerves, particularly of the autonomic system, and of the manner in which impulses are generated. Drugs and poisons act like the agents of disease, and the application of the principle of the reflex arc is necessary for understanding the action of remedies.

1. The Problem of Ill-health.

While fully recognising the great additions that are being made to medical knowledge in recent years, and while appreciating the benefits which the application of the knowledge has conferred on the practice of medicine, yet we must not shut our eyes to fields which are practically unrecognised, but which are essential to the progress of medicine. The ardent investigator should ever be more ready to analyse his failures than to contemplate his success, and if we take a wide outlook on medicine, we shall have little difficulty in detecting failures. If a survey be taken of modern medicine, the remarkable fact comes clearly out that, notwithstanding the widespread interest in medical research, the most obvious of all problems whose solution is necessary for the rational practice of medicine remains practically untouched.

Every patient who consults a doctor does so because he feels ill, yet if we ask what is ill-health, or what is the nature of the phenomena of ill-health, we shall ask in vain, for nowhere is there to be found an understanding of the nature of the simplest phenomenon of this kind. In a vague sort of way attempts have been made to understand the nature of ill-health and of the changes that lead to death. At one time pathology was expected to give this kind of knowledge, but it has failed. The reason for this failure will be grasped when it is realised that the phenomena of ill-health and death are due to the disturbance and cessation of active living processes, and that neither the post-mortem examination nor the microscopic examination of damaged organs can reveal these processes. It was expected that bacteriology would supply this kind of knowledge, but while it may reveal an agent which provokes ill-health, it throws no light upon how that agent produces ill-health. Methods of investigation are being borrowed from other sciences, but although chemical analyses, the X rays, the electro-cardiograph, and other devices may be adapted for clinical investigation, and although they have proved of value, they fall short of expectation for the simple reason that while they may reveal the result of disease they do not reveal the process which is concerned in its production.

Common Diseases.

The hampering effect of the absence of this kind of knowledge upon medical progress and practice is seen in many fields. Crusades and campaigns are being organised against diseases whose effect upon the body is not understood beyond the fact that ill-health and death result. Manifestly, if we are to combat a danger we must know the nature of the danger, and while we know that tuberculosis, cancer, and heart disease produce ill-health and death, we do not know how they do it. When an enterprise is undertaken which requires a certain kind of knowledge, and it is assumed that this knowledge exists when it does not exist, it does not require the gift of prophecy to foretell the end of such an enterprise. It is for this reason that the path of medicine is strewn with enterprises that have failed.

Articles and speeches, depicting the progress of medicine in glowing terms are becoming stereotyped with constant references to certain successes, particularly in tropical diseases. If more attention were directed to the common diseases that afflict the people in this country a better perspective of the progress of medicine would be obtained. If the present state of knowledge and practice regarding these diseases be compared with the state when I entered practice 45 years ago there is some difficulty in recognising where progress has been made. Occasionally new methods of diagnosis may bring to light signs that before could not be detected. We may find a new remedy used to relieve distress, and many new surgical operations performed which were not done then, but if we look at the mass of people in ill-health, only a minute percentage have gained benefit. The so-called minor ailments, some of which are the beginnings of serious ill-health, the numerous digestive troubles which do so much to impair health, are just as common and as little understood now as then, and we are just as helpless in face of the grave acute illnesses.

Classification of Disease.

A good conception of the lack of progress can be gained from the perusal of the index of diseases which numerous learned bodies issue from time to time. The study of such books reveals the total absence of any system of classification of the slightest value. Time and again attempts have been made to classify diseases on some logical basis, and all have failed, simply because a knowledge of disease adequate for the purpose does not exist. We sometimes find the " cause " used for a logical classification, but as in the vast majority of cases of ill-health the cause is unknown, the basis has to be mainly guessing—that is to say, the logical classification has to start with what is bound often to be a false premise—and we know where that leads. Again, we find morbid anatomy used as a basis for classification, but here again failure is bound to result, for the diseased organ is the result of those processes which caused ill-health and death, and we know so little of these that it is not possible to recognise the connexion between them and the diseased organ.

All attempts to classify common ailments or diseases have resulted in a nomenclature where signs and symptoms, morbid structures, and fanciful diagnoses, and even physiological manifestations, are mixed together in hopeless confusion. This, again, is because the nature of ill-health is not understood.

---

* The material for these articles was obtained from observations in which every member of the Institute participated. Part of the expenses incurred was contributed by the Medical Research Council and the Carnegie Trust.

Nature of Ill-health.

An essential problem in the practice of medicine in dealing with a sick person is to know what it is that makes him ill and why he dies. To say that he has a pneumonia, or that he is infected by the pneumococcus microbe is quite true, but that is not enough. The microbe may be the agent and the inflamed lung one of the results, but they do not tell us why he is ill. The doctor is called in because he is supposed to have the knowledge and to be able to use remedies to combat the illness; this he cannot do, for he does not know the nature of the illness. One doctor may fancy the lung needs treatment, and applies a poultice to the chest; another that the heart is "failing" and gives remedies for the heart; and a third that the blood is not sufficiently aerated, and prescribes oxygen; while another attacks the ill-health with a vaccine, and so forth—no one really knowing what to treat. A simpler example of this defective knowledge is illustrated in cases of poisoning. No pharmacologist or toxicologist can tell us the action of a poison like arsenic in causing ill-health and death.

Pain.

This defect in our knowledge will be even more fully realised if we consider how little we know of the most clamant and universal, and if we understood it, probably the most instructive of all the phenomena of ill-health—pain. We can reason that pain originates from impulses sent out by the cells of an organ or tissue whose normal condition is disturbed, that these impulses are taken up by certain nerves, and transmitted to the central nervous system, where they produce the sensation of pain, and the sensorium refers the pain to some part of the body. But if we ask what tissues are capable of producing these impulses, what nerves receive these impulses, what morbid states underly their production, and how comes it that the pain is referred to places sometimes remote from the organ or tissue whose disturbance gives rise to the impulse—such questions cannot be answered, except by guesses. What is true of pain is practically true of every other symptom, whether it is a sensation experienced by the patient or a sign perceived by the unaided sense of the experienced observer or detected by the aid of some mechanical device.

Records.

A great deal of time and labour is spent on getting records, and an enormous mass has been accumulated. Everyone recognises that they should be of inestimable value, but somehow or other the good results are never commensurate either with expectations or with the labour spent. If one asks a physician or surgeon what use he makes of the records of his predecessors, who it may be, for a quarter of a century, had been piling them up, he will reply that nobody ever looks at them! This fact has been recognised, and strenuous attempts are being made to remedy this state of affairs. But there is little prospect of success so long as we remain ignorant of the phenomena of ill-health. The most favoured method to-day is to have each patient examined by a great many specialists. Each specialist may find something wrong, and all their findings are carefully recorded. But such records are of little help, as they do not tell us the outcome of the complaint. This is recognised in some quarters, and the patients are to be "followed up." But what is it that should be watched in the following up, and which of the specialists is to do it? The object is to note the modification in the symptoms with the progress of the disease, but in the present state of knowledge of the nature of symptoms, only a very imperfect or useless record can be kept.

Again, such records start long after the onset of the complaint, and little understanding of how the present state was reached can be found. This has been recognised, and hospital physicians are spending their time in the out-patient department. But, as they have been educated only to recognise the "physical signs" of disease, which are often produced when the disease has done damage to the organ, there is little prospect at present of success, seeing that in the early stages of disease there are often no physical signs. Before there is any prospect of success there must be a far better understanding of those symptoms by which ill-health is recognised.

The significance of this will be understood if we keep clearly in our mind the main objects of records which are, to record the symptoms which will enabl a diagnosis and a prognosis to be made. Th symptoms for these purposes are not necessarily th same. When a patient is ill he is not so much concerned with the name of his complaint, as whether h is to get well or not. The symptoms by which w recognise scarlet or typhoid fever are not those b which we can give a prognosis. Moreover, th knowledge of whether he is to do well or ill forms th basis of a rational treatment. To put the matter i another way, we may find in a patient some definit sign as a heart murmur, pleuritic friction, spitting o blood, and it is necessary to assess their value—t find out what relation they have to the patient' future health. To give statistics that a certai percentage of people with murmurs die or that certain percentage of consumptives have suffered fro pleurisy or hæmoptysis may be true, but they do no tell us what is to happen to any particular individua When a person is in ill-health there is always presen a number of symptoms, some of which afford th means of diagnosis, but it is the nature and kind o the symptom which determine the prognosis. Th aphorism that no grave prognosis in heart affection should be based upon the presence of only one sig holds good for practically all other organs. Record ought to give this kind of information, but they wi never do it while symptoms are neglected, and unt this is remedied the keeping of records will continu to be of little value.

Treatment.

A further evidence of the hampering effect of th lack of knowledge of ill-health is seen in treatmen If treatment is ever to become rational and intelligen it is necessary to know the condition we want to trea As the condition is invariably made manifest b certain signs or symptoms—that is, by the phenomen of ill-health—we must know what these are and ho they are produced, but while we are ignorant of the nature our treatment is bound to be haphazard an empiric. It is necessary to know how our remedi act. While we may recognise that they do act, it seldom that we have any clear idea of how they ac We know castor oil may relieve constipation, but w know as little about the manner of its action as we d of the nature of constipation. In recent years portentous list of new remedies has been introduce under imposing titles, as vaccine therapy, seru therapy, chemotherapy, psychotherapy, vitami therapy, endocrine therapy, substitution therapy, & While each is claimed to give good results, no perso has a real knowledge of the action of the vario remedies, and we are therefore driven to speculati for an explanation. Hence the principles of mode therapy are the same as those which have been in u from time immemorial—the giving of a remedy who action we do not understand for a condition of who nature we are ignorant. If this is grasped it will seen that there is no prospect of a truly scienti principle being evolved until we understand the natu of the phenomena which we wish to treat.

We might present the subject in another way. W frequently meet with people in ill-health who have ha all their teeth removed, because the doctor thoug that in some way the teeth caused the ill-health, b who have gained no benefit from the removal. It known that adenoids may result in ill-health in so people, but in the vast majority of people they have ill-effect—yet the fashion of to-day is to remove the Appendicitis causes ill-health and death in so people, and great numbers of people have the appendixes removed, with no benefit to their healt Surgical literature will be searched in vain for knowledge of the nature of the symptoms of appe dicitis, or the manner in which they are produced, while no description is given of those phenomena which would guide to understanding the danger, or absence of danger. Large numbers of perfectly healthy people are rejected for life insurance, and for entrance into the Services, have their lives restricted, and are subjected to various forms of treatment, because some sign as a murmur or an irregularity of the heart is detected. Modern medicine is developing along new lines, in which numbers of specialists are combining to make a more thorough examination of each patient. That each specialist may frequently find symptoms belonging to his special department is to be expected, seeing that in a sick man every organ may be disturbed. But if each or all of them is asked what is the nature of the ill-health which is provoked by the disturbance, no clear information can be obtained. That does not mean that each specialist may not do good by his treatment, or that such a combination may not be successful, but the point is that there is not that knowledge which enables the specialist to understand the relation of the disturbance which he detects with ill-health, and in consequence of the absence of this knowledge he is forced to treat patients whose sufferings cannot be relieved on the same lines as those who can be relieved.

Specialism.

Did space permit it might be profitable to discuss the reason for the neglect of such an important field of knowledge—it suffices here to point out that it is in a great measure the outcome of specialism. Medicine has become so large that it is necessary for men to limit themselves to special fields. On this there follows the danger inseparable from specialism in all spheres, the inability to see the whole field, with the result that each investigator is so engrossed in his own narrow sphere that he does not recognise that other fields as important, or even more important than his own, are being neglected. A man with a limited experience is likely to be a man with a narrow outlook. It is worth while to note that with few exceptions (as specialists in venereal diseases) specialists have no opportunity for seeing patients in the early stages of the disease in which they specialise, and as a consequence the early stages of the vast majority of diseases cannot be recognised.

Many examples of the evil effects of specialism in the practice of medicine could be cited, and the following may be taken as an example. A problem which is ever cropping up in general practice is how to deal with patients with affections of the heart who become pregnant. A perusal of recent obstetric books shows that the writers have so imperfect a knowledge of this subject that their opinions are of little value. The heart specialist has never had the opportunity of studying the effect of pregnancy in either the normal or diseased heart. The absence of this kind of knowledge often has calamitous results.

The Laws Governing the Production of Phenomena.

The living body is composed of organs which are continually being exposed to impulses from without and from within, to which the organs react. The agents which are capable of originating such impulses and the reactions they produce are infinite in number. As a great deal of medical investigation is concerned with these reactions, there is no limit to the number of methods that may be devised to produce them or to detect them. So long as research is content with the mere accumulating of new facts of this kind little progress can be expected, though occasionally out of the great mass some facts of value may be discovered, and such discoveries are supposed to justify these procedures.

Looking at the matter in this light, the prospects of achieving the great aims of medicine are not hopeful, and the question arises: Is there not a better way? To find an answer it is worth while to consider how other subjects dealing with natural phenomena have made progress. Such subjects as chemistry, physics, botany are making great strides, and if we inquire into the reason it will be found that in their early history they were in the state that medicine is in at present, in that a great mass of detail was accumulated, but so confused that it was not possible to understand its significance. In course of time the need for a classification based upon rational grounds was recognised, and in each case this was found in the discovery of certain "laws" which enabled the mass of details to be classified according to their affinity in nature.

The phenomena produced in the living body in health and disease are natural phenomena, and are thus subject to definite laws. There is no prospect of understanding the phenomena which research is revealing every day until the mass of details is classified according to their affinity in nature, and this cannot be done until the laws that underlie the production of these phenomena are discovered.

The subjects just mentioned were not really entitled to be considered as sciences until the laws which governed the production of their phenomena were recognised. After that the subjects became not only easier of comprehension, but a guide was given which has led on to continuous progress. The want of knowledge of such laws is one reason for medicine's unprogressive position, and there is little prospect of material progress until they are discovered. Such is the conception which influences our work in St. Andrews. No one recognises the difficulties more than we do, and we put forward here some of our attempts knowing them to be—like all first steps—halting and uncertain.

2. THE NEW OUTLOOK.

The recognition that there is an urgent need for a new outlook in medicine is not the result of a superficial view or of a hasty survey. It is 44 years since I entered upon the practice of medicine as a general practitioner. After a few years it gradually dawned upon me that I was profoundly ignorant of the nature of the complaints for which I was consulted. If a patient had a pain I might be able to give relief, but when I asked myself how was the pain produced and how my remedy acted, I had to admit I did not know. When I detected in a patient a murmur in the heart, or an irregularity in its action, I looked upon these as signs of serious significance and proceeded to treat them according to the fashion of the day. But when I asked myself in what way they indicated danger I could not tell. The same blank ignorance faced me when I looked closely into nearly every form of complaint—whether trivial or serious. At first I thought my ignorance was peculiar to myself, but I soon found that neither the consultants to whom I brought my patients, nor the books I read, could give me the kind of knowledge I wanted.

I therefore resolved 40 years ago to improve my own knowledge, and for that purpose I set myself two objects—(1) to find out the nature and mechanism of individual symptoms, and (2) to find the bearing the cause of the symptom had on the patient's health in the present and in the future. From that time onward I have steadily pursued this inquiry. Needless to say, progress has been slow and difficult. One great obstacle was my profound ignorance of the manner in which the functions of the body were carried on. In striving to remove this ignorance, I discovered that the knowledge essential to the attainment of my object in many instances did not exist, and I had to devise measures to get this knowledge. Many were the failures, but gradually a measure of success was achieved. I kept reviewing the steps I had taken, and studied the reasons of success to find the reason for the failures, till I finally was able to understand the reason for the slow progress of medicine in dealing with the ill-health common among the people, and recognised a great field of investigation which had been neglected, but which is absolutely essential for the progress of medicine and its intelligent practice.

My experiences led me to see a possible way in which this field should be explored, and four years ago the St. Andrews Institute was started with the definite object of studying the nature of ill-health. In the first instance it was incumbent that this inquiry should be in the hands of those who had the opportunity. As the main object was to study the life-history of disease, it was necessary that the investigators should watch the disease from its onset to its finish. It was necessary, therefore, to study the history of ill-health from its onset till its termination. For this purpose it was necessary to understand the phenomena which constituted ill-health. Not only must the investigator have suitable opportunities, but he must be trained to know what to observe. As ill-health is made known only by the sensations of the patient or the detection of signs by the doctor, it was necessary to comprehend the nature of symptoms. I had long ago found that the knowledge of symptoms was so defective that there was no hope of any success till it became far fuller.

Having thus clearly recognised the need of research and envisaged our object, it was necessary to organise a method that would enable the research to be pursued in a systematic manner. The opportunities to which reference has been made of studying disease from its onset to its termination were afforded only to the general practitioner, and it was evident he must take the principal part in the investigation. Many people may have opportunities for seeing ill-health in different stages, but these avail little unless a far better knowledge of the phenomena of ill-health is obtained than at present exists. It was recognised that to obtain this knowledge a prolonged investigation would have to be made into the nature of symptoms, and for this purpose the opportunities of the general practitioner were not enough. To help in this work the professors of anatomy and physiology of the St. Andrews University, a bacteriologist, a chemist, and an expert radiologist are associated with the general practitioners. In order that we might pursue our work systematically we discussed our object and recognised that the highest aim of medicine was to prevent disease. To prevent disease it was necessary to know the circumstances that caused or favoured its onset, and to know the course it pursued from the onset to its termination.

Realising this as our object we first had to get a clear conception of what we meant by ill-health or disease.

Ill-health is commonly spoken of as "disease." We wanted a clear conception of what was meant by disease, and for our purpose we defined ill-health or disease as *the reaction of the body to a noxious agent.* The reactions of the body were what is usually understood as the symptoms of disease, or the phenomena of ill-health. The noxious agent might be, and often is, a microbe. As the agent is rarely discoverable, and as disease or ill-health is only recognised by the presence of symptoms, we found it necessary to begin our work with the study of symptoms. We found that already there had been accumulated a great mass of symptoms, and to add to that mass by discovering new symptoms would not lead to progress but the reverse. A little consideration revealed that when a man falls ill every organ may be disturbed, so that there is no limit to the number of symptoms a sick man may develop, and the search for new symptoms and the invention of new devices for that purpose and the introduction of methods from other sciences would but add to that great mass of chaotic detail which at present effectively obscures the path of progress.

The first step lay in an endeavour to reduce the mass of symptoms to order and to classify them on some definite principle, such as their affinity in nature. As all phenomena in nature are subject to definite laws, we recognised that symptoms are natural phenomena, and their production must be subject to definite laws, and we set out to find them. Symptoms, apart from those due to structural changes, were found to be due to an increased or decreased action of some organ, that is to say, to a modification of normal activity. The activity of an organ depends on two parts, one consisting of cells with a specific function and another of cells that regulate the activity of the organ. The former consists of those cells whose action gives rise to the special function of the organ, as the contraction of muscle cells, the secretion of secretory cells, the sensations produced by the cells of the sensorium (brain). The activity of these cells are regulated by nerves or other structures with the same function as nerves. By the action of these regulating nerves the organ functions according to the requirements of the body. The variation of cell activity due to these requirements, as well as the variations which result in symptoms, are dependent on these regulating nerves to a great extent. These nerves are brought into action in a particular way. The organs of the body are continually subject to a stream of impulses which enter from without (through the skin and special senses) or are produced in the body by the activity of the organs themselves. These impulses, wherever they arise, are conveyed by the nerves to the different organs and modify their functional activity.

Our inquiry in this way led us to recognise that a great many symptoms, and especially those that indicated ill-health, were due to disturbance of the mechanism or processes which regulated the function of organs. Moreover, death itself was due to the suspension of activity of organs necessary to life, and this suspension was brought about by interference with those regulating processes. As the mechanism or process which results in a modification of the functional activity of the organ involves the transmission of impulses from one organ to other organs—as from the skin to the muscle—is usually spoken of as a "reflex" or "regulating process," we put forward the theory that a great class of symptoms was produced by the disturbance of these normal processes. What is meant by this can be illustrated by the consideration of some of the organic reflexes. In this inquiry we paid a good deal of attention to those symptoms whose production could be watched and the source recognised. Of these the organic reflexes afforded the best opportunity, as in the study of uterine contraction at child-birth. Here it was noted that the slighter contractions caused few reactions. As they increased in severity the reactions increased—the heart rate increased, the face flushed, the muscles of the abdominal wall were violently contracted, the breathing was held while "bearing down," great pain was felt in a definite area, at times nausea was experienced, with a flow of saliva and vomiting. All these phenomena were distinctly related to the contraction of the uterine muscle, and there was a relation between the number of organs stimulated to increased activity and the strength of the contraction. All the phenomena described above occur as a normal event. The same phenomena can occur as a result of a morbid condition. Under normal circumstances micturition takes place in a similar manner, with, however, only a few reactions. The impulses from the bladder produce relaxation of the sphincter, and it may be a mild contraction of the muscles of the abdominal wal with a sensation produced by the urine passing over sensory parts of the urethra. If there be a stone in the bladder, towards the end of micturition the bladder is stimulated to violent contraction as in the case of the uterus, with the production of a similar set of symptoms—pain in a definite region, straining and "bearing down" and disturbance of othe organs. Defæcation is normally accompanied by a similar series of reflexes, but under abnormal circumstances, when the bowel is stimulated to violent contraction, we get a widespread disturbance of many organs, resulting not only in pain, "bearing down," but nausea, vomiting, sweating, and even syncope.

The similarity of the phenomena produced by these reflexes, normal and exaggerated, to the phenomena of bowel, renal and gall-stone colic, leaves little doubt that they are produced in the same way and indicate that the phenomena associated with the colics are due to an increased activity of norma reflexes. Based upon these observations we put forward the theory that a great mass of symptoms were produced by the disturbance of normal reflexes.[1]

Recognising that a great group of symptoms was the result of an increase or decrease of functional activity, we then inquired what was meant by stimulation and inhibition. This has led to a long and intricate inquiry and has exposed many avenues for investigation. Before these can be explored, much preliminary work of an elementary kind has to be completed, and here we indicate the lines we are pursuing at present.

3. THE PRINCIPLE OF THE REFLEX ARC.

When we had advanced so far and formulated the theory that symptoms of disease were produced by the disturbance of normal reflex processes, we were confronted with the problem of its application. Merely to formulate a theory without demonstrating ts usefulness is futile, for the proof of the validity of a theory is only to be found in its application to the solution of problems. We attempted its application n various ways. In the course of these attempts ve recognised the very obvious matter that identical symptoms appeared in a variety of ways. Vomiting, or instance, could occur from impulses arising in remote organs, as the ureter, the brain, the fauces, as well as from the stomach itself. Lachrymation ould arise from different causes. Pain might appear n the same situation from disturbance at different evels of the nervous system. Identical variations f the pulse might arise from disturbances at a number of different places.

FIG. 1.

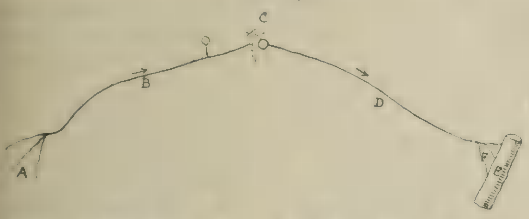

Diagram of a simple reflex arc. A, the receptor of an afferent neurone; B, C, the centre of the arc in the central nervous system; D, the efferent neurone to the effector organ; E, the arrows indicate the direction of the impulses.

As such symptoms are but the manifestation of the deranged function of the organ, it was necessary to now how the deranged function came about, and this nvolved the question of the process concerned in ncreasing or decreasing functional activity. It is manifest, therefore, that before we can appreciate he nature of a symptom we must have a knowledge f the parts concerned in regulating the function of he organ, of whose disturbed function the symptom s the evidence. This regulating mechanism consists f a chain of units (neurones) which convey impulses o the organs, and result in a modification of the unction of the organ.

The recognition of this theory compelled us to look more closely into the process itself, and to study the nits of which it was composed. In this endeavour was found impossible to recognise the part played y each unit while the organ was working in a normal manner, but it was often possible to do so when the nit ceased to function or acted in an abnormal manner. By following this line of investigation we et a knowledge not only of the mechanism which roduces some symptoms, but of the functions of rgans and structures which so far have baffled nquiry. This simple concept that the function of a art is easier to be recognised when it fails than when is acting normally is one of the principles which we nd useful in our work.

As the reflex or regulating process is built up of a eries of units the question arises, at which unit does the disturbance take place. Thus, if we represent the process by a simple diagram, as in Fig. 1, we find a number of units. There is the receptor (A) at which a stimulus is received. The stimulus is conveyed by the afferent nerve fibres (B) to the centre (C), where it is taken up by the efferent nerve (D), which conveys it to the effector organ (E), which gives a response. It is the abnormal character of the response which constitutes a symptom. Any one of the units which constitute this arc is liable to be affected by the agents of disease, so that the normal function of the unit is disturbed and an abnormal effect — i.e., a symptom—may be produced. While the typical effector organ is the muscle, yet it may be a gland, and in our view it may be the sensorium, as those organs are influenced in a similar way. Taking pain as an instance, we recognise a pain complex built up of a series of cerebro-spinal neurones. Thus there is a receptor organ A at the periphery, and the effector organ E is the sensorium (Fig. 2). When an adequate stimulus reaches any part of this complex the sensorium perceives the pain and refers it to the peripheral distribution at A. Thus a stimulus applied to the skin at A, or entering the complex at Y (as in toothache) or at Z (as in herpes zoster), the pain is referred to the peripheral distribution at A. If an adequate stimulus arises in organs (V) not supplied with cerebro-spinal nerves, but only with autonomic nerves, it is conveyed by these autonomic nerves to the central nervous system, and there affects the pain complex at C.

FIG. 2.

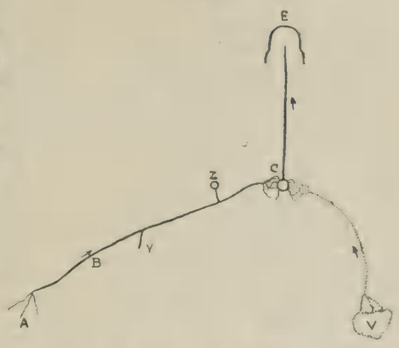

Diagram of the mechanism of pain. Impulses affect the receptor at A and are conveyed by the afferent neurone to the central nervous system, and to the sensorium E. Any impulse reaching this mechanism in any part of its course causes pain which is referred to the periphery at A. Impulses entering at Y, as in toothache, or at Z, as in herpes zoster, or at C from the viscera V produce pain which is referred to the periphery at A.

FIG. 3.

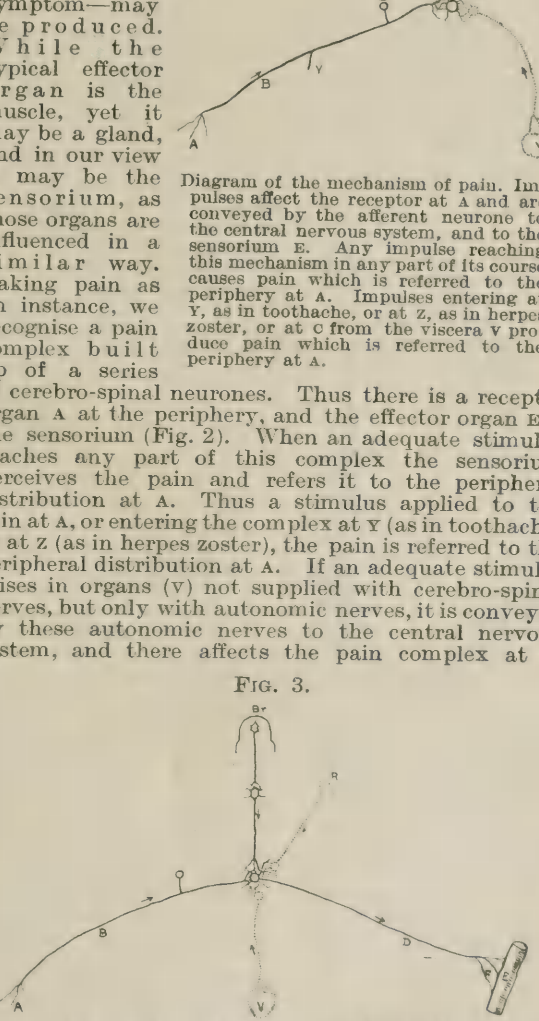

Diagram showing the different sources from which impulses may cause contraction of a voluntary muscle, E; from the brain (Br) in voluntary contraction; from the skin (A) in a cutaneous reflex; from the viscera (V) by the autonomic nerves as in visceral disease; in taking a part in organic reflexes as in respiration (R), parturition, vomiting, &c.

According to the principle of referred pain the sensorium refers this pain also to the periphery at A.

The regulating or reflex process is, however, not so simple as represented in the diagram. The connexion in the central nervous system is complicated by neurones interposed between the afferent and efferent neurones, and influences may reach and affect the arc from sources other than the periphery A. Thus, in the case where E, the effector, is a voluntary muscle, and A, the receptor, is in the skin (Fig. 3), the muscle contracts in response to a stimulus or impulse from A as in the ordinary cutaneous reflex. But the same muscle is under control of the will, so that impulses from the cortex of the brain (BR) also cause it to contract. Again, the same muscle may become rigid and hard from impulses arising in some of the viscera (V), as in the hardening of the abdominal muscles in gastric ulcer, appendicitis, &c. Voluntary muscles contract also in response to the "organic reflexes," as in respiration (R), vomiting, defæcation, &c.

---

[1] The Theory of Disturbed Reflexes in the Production of ymptoms of Disease. Report of the St. Andrews Institute for linical Research, 1922, vol. i.

These complications of the process are all from parts outside the organ itself. Every organ possesses within itself structures concerned in regulating its functions. Little is known about these structures and their function, but the closer study of the matter leads to the conclusion that there are in all organs such structures, and they have a distinct purpose to serve, whose disturbance again leads to the production of symptoms. In no organ has the recognition of these structures been carried so far as in the heart, and until their discovery in recent years the problems connected with the manifestation of the heart in health and disease were incapable of solution. It may be pointed out that the recognition of the functions of the different structures has largely resulted from clinical study.

The diagram Fig. 4 shows the intrinsic regulating mechanism of the heart so far as it has been brought to light. The diagram represents two sets of structure, those concerned with the specific function and those concerned in regulating that function. The muscle wall of the auricle (A) and of the ventricle (V) represents the specific functional structures, the sino-auricular node (S.-A.N.), the auriculo-ventricular node (A.-V.N.), and bundle (A.-V.B.) represent the regulating mechanism. The stimulus for contraction arises in the S.-A. node, and, after causing a contraction of the auricle, stimulates the A.-V. node into activity. The A.-V. node then discharges impulses which are conveyed to the ventricle, which responds by a contraction.

FIG. 4.

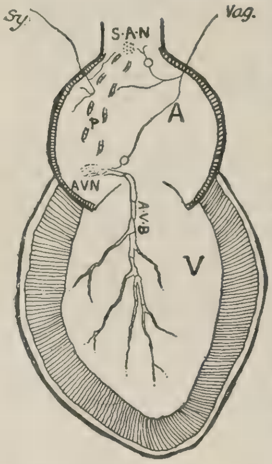

Diagram of the heart showing the parts concerned in regulating the rate and rhythm of the heart and the parts concerned in the contraction of the heart. In the former there are the sympathetic and vagus nerves, the sino-auricular node (S.-A.N.), the auriculo-ventricular node (A.-V. N.), and bundle (A.-V. B.). In the latter there is the muscular wall of the auricle (A) and of the ventricle (V).

When any agent or circumstance increases or decreases the heart-rate, with the normal rhythm, it is the S.-A. node which is being acted upon. This has to be kept in mind, for there is a tendency to assume that the rate of the heart is in some way dependent on or associated with the functional capacity of the heart. Thus the amount of increase in rate in response to effort has been taken as a measure in "exercise tests." If it be realised that the rate in response to effort is due to the susceptibility to stimulation of the S.-A. node it will be seen that the relation of rate to the functional efficiency of the heart is merely incidental. Alterations of rhythm may arise in consequence of disturbances at any unit of the regulating mechanism shown in Fig. 4. What is true of the heart is true of every other organ. There is an intrinsic mechanism in the stomach, bowel, kidney, liver, and, indeed, in every organ, including the voluntary muscles, which is barely recognised, but whose investigation is needed if we are even to understand the phenomena of ill-health.

The advantage of using the reflex arc as a guide for research is that it compels the study of the individual units of the arc, and this study brings out defects of our knowledge in a striking way, and not only brings them to light but may enable us to recognise how the defect can be made good. Each unit of the reflex is composed of a number of cells, and the question arises what part do they play individually and in combination in the performance of the normal function of the organ, and also in the production of symptoms. When it is realised that symptoms are but the evidence of an increase or decrease of functional activity, the question at once arises, how do these cells behave? This leads to further questions: What is stimulation, and what are these cells doing during periods of functional activity and during periods of quiescence? The attempt to answer these questions has led to the recognition of a very important law—the law of fluctuation—which has thrown a new light upon some features of functional activity.

THE SIMULATION OF
ACTIVE PULMONARY TUBERCULOSIS BY
PAINLESS MAXILLARY SINUSITIS.

BY A. LOWNDES YATES, M.D. LOND.,
F.R.C.S. EDIN.,
SURGEON IN CHARGE, EAR AND THROAT DEPARTMENT,
WOLVERHAMPTON GENERAL HOSPITAL; CASUALTY
SURGEON, QUEEN'S HOSPITAL, BIRMINGHAM.

DURING the past 18 months my attention has bee directed to certain cases of patients, who, whil exhibiting all the symptoms of pulmonary tuberculosis were, in fact, suffering from sinusitis of such a natur that no localising symptoms were present. That man of these patients had been diagnosed as pulmonar tuberculosis was not surprising; they generall presented not only the symptoms of tuberculosis— namely, cough, often waking the patient at night morning sputum, yellow or green in colour, and ofte nummular; progressive wasting, a rise of temperatu in the evening and after exercise—but also certai physical signs in the chest due apparently to bronchitis which, while not typical of tuberculosis, are sufficien to render it extremely difficult for the physician t negative the diagnosis of pulmonary tuberculos with which the patient is sent to him, whil the fact of the absence of tubercle bacilli in th sputum does not, apparently, negative the presen of pulmonary tuberculosis.

Literature of the Subject.

Previous to the year 1916 medical literature co tained little of note in relation to this subject. I 1914 StClair Thomson,[1] discussing the complicatio of sinus disease, wrote "The same cause (nasal an sinus suppuration) often explains the inveteracy bronchorrhœa." In 1916 Rist[2] called attention the association of chronic bronchial cough with chron infection of the nasal sinuses which was frequent diagnosed as pulmonary tuberculosis. In 19 Sergent[3] corroborated Rist's statements and referr to the cases as "faux tuberculeux." He reported th an incorrect diagnosis had been made in one-third the cases of supposedly tuberculous soldiers, and th most of the mistakes occurred in the cases of m suffering from chronic bronchitis associated wi chronic infection of the nose or nasal sinuses. Bo Rist and Sergent stated that correction of the nas disease resulted in the cure of the bronchitis. 1919 Webb[4] referred to the dependence of many for of bronchiectasis and bronchitis on disease of t accessory sinuses. In 1920 Mullen and Gilbert referred to the association of nasal disease with chro bronchitis. Also Mullen and Ryder[6] reported experimental lesions of the lungs produced by inha tion of fluids from the nose and throat. In 1921 We and Gilbert[7] reviewed the literature of the subj and reported 38 cases of bronchiectasis or bronchi associated with sinus infection. In 1922 Mackey,[8] a result of a bacteriological examination of the sputum and nasal discharge in 300 cases of bronchitis, stated that there was a definite connexion between the infection of the nasal passages and the liability to bronchitis. In 1923 Dunham and Sklavhem[9] drew attention to the same subject from the point of view of X ray diagnosis of lung conditions. Also McIntyre[10] reported on 37 cases which presented pulmonary manifestations incident to infection of the nasal sinuses, some of which showed typical febrile remissions characteristic of pulmonary tuberculosis.

Nasal Protective Mechanism.

In order to make clear the condition met with in these cases of sinusitis it is necessary to refer briefly to the nasal protective mechanism. When micro-organisms contained in the inspired air pass into the nose they are caught in the mucus secreted by and covering the surface of the nasal mucous membrane, and, enveloped in mucus, are passed backwards by the action of the ciliæ of the mucous membrane into the naso-pharynx. If, owing to the numbers of the organisms reaching the nose, or to the presence of some minor abnormality within the nose of such a nature as to hamper ciliary action, the micro-organisms are not removed sufficiently quickly, the latter multiply within the nose, and the resulting increase of toxin produces a reaction in the form of a congestion of the mucous membrane succeeded by an increase of mucous secretion. If the organism continues to multiply more quickly than it can be removed, an increase in the number of mucous glands takes place. Normally this reaction is sufficient to rid the nose of the presence of micro-organisms other than those normally passing into the nose with the inspired air. If, however, there is either a dental infection of the antrum or some obstruction to the opening of the antrum into the middle meatus, the secretion of mucus continues, but its removal by the ciliated epithelium is delayed. If the micro-organisms have time to multiply to such an extent that their toxins paralyse the ciliary epithelium, the mucus and pus collect within the antrum, and the condition known as an empyema of the antrum results. If, however, the obstruction is slight no empyema is formed; the ciliæ remain active and pass the mucus with its content of toxins and micro-organisms into the middle meatus, and backwards until it reaches the naso-pharynx, from which it is passed along the posterior wall of the oro-pharynx to the pouch between the epiglottis and the tongue and to the posterior part of the larynx, where it comes to rest in the space between the arytenoids and upon the posterior surface of the arytenoids.

Now in this latter case, where the obstruction is slight and no empyema is formed, the mucous membrane of the nose, in front of the opening of the maxillary antrum, rids itself of infection and appears on examination to be normal. But the mucous membrane of the nasal passages behind the opening of the antrum and that of the pharynx shows marked reactive changes. These reactive changes are caused by the flow of pus, or mucus containing micro-organisms and toxins, acting upon the mucous membrane. It is this pus or infected mucus which, passing down the pharynx, collects in the laryngo-pharynx and in the morning is expelled by coughing. The delay in the removal of the infected mucus allows of toxic absorption and as a result in some cases wasting, evening temperature, and night sweats take place. While a condition such as that described may produce symptoms very similar to pulmonary tuberculosis and hence lead to errors of diagnosis, it may also exist in the presence of pulmonary tuberculosis. The presence of this disease, however, modifies the physical signs found in the pharynx and larynx, and the condition of sinusitis complicating a pulmonary tuberculosis is therefore separately described.

Signs of Painless Maxillary Sinusitis.

The signs met with in the form of maxillary sinusitis which is apt to cause wasting and other signs of toxæmia, in the absence of pulmonary tuberculosis, without referred pain or anterior nasal discharge are as follows: By anterior rhinoscopy, the nose generally appears normal and the airway as a rule is good on both sides. There is, however, generally some slight enlargement of the middle turbinate on the affected side. By posterior rhinoscopy, the naso-pharynx contains muco-pus or mucus in excess. The posterior end of the middle turbinate of the affected side is enlarged, its outer or meatal surface may show irregular hypertrophy, and muco-pus may commonly be seen in the posterior end of the middle meatus. The soft palate is thick, being especially thickened upon its posterior surface, where a rounded thickening takes place above the posterior surface of the uvula. The reflex sensibility of the soft palate is generally greatly increased, and cases are met with in which spontaneous vomiting occurs, ceasing after a few days' painting of the pharynx with silver nitrate. The posterior wall of the oro-pharynx is red, and shows on its surface a network of blood-vessels between which the mucous membrane is raised above the surface and of a velvety appearance. The posterior surface of the tongue shows marked hypertrophic masses, particularly in and at the sides of the glotto-epiglottidean pouch.

The laryngeal changes depend upon the position of the epiglottis, and do not occur when the epiglottis is tilted backwards so as to touch the posterior pharyngeal wall. When the epiglottis is seen in its normal situation the laryngeal changes are as follows: The whole larynx is red, the posterior surface of the arytenoids is greatly hypertrophied, and the mucous membrane of the space between them has generally hypertrophied to such an extent that the mucous membrane covering the arytenoids forms an oblong bar of red colour from which the false cords take origin. In this hypertrophied mass the movements of individual arytenoids are difficult to distinguish, while a prolongation forward of the hypertrophy is often situated centrally and renders a view of the posterior commissure difficult to obtain. The mucous membrane covering the inner surface of the trachea is red, thick, and actively secreting, while the tracheal rings are rarely seen through the mucous membrane. The tonsils in these cases are in most cases hypertrophied, and I find that on draining the affected sinus the tonsillar enlargement often disappears. The tonsil on the side of the affected sinus is practically always the larger.

The condition found in the pharynx and larynx, as a result of infection by carious teeth of the maxillary antrum, is identical with the above; that due to dental sepsis without antral infection is similar, but of less severity, and the signs observed by posterior rhinoscopy are absent. Occasionally the occurrence of sinusitis with the most advanced stage of laryngeal tuberculosis produces a somewhat similar clinical picture, but the intense redness and congestion of the larynx, coupled with the ulceration in the region of the posterior commissure of the larynx, and possibly the spread of this ulceration into one or both cords, prevent errors of diagnosis.

When pulmonary tuberculosis and sinusitis are present together the signs are considerably modified. Before describing them it is, however, necessary briefly to describe the conditions present in the nose and throat in pulmonary tuberculosis without sinusitis. Certain conditions are so regularly found in the nose and throat in patients suffering from pulmonary tuberculosis when neither laryngeal ulceration nor sinusitis are present that they must be regarded as results of this disease. There is a pallor and lack of reflex sensibility of the larynx, oro-pharynx, and laryngo-pharynx, and to a less extent of the naso-pharynx; the mucous membrane throughout is thin and lacks reaction; the larynx is pale, the arytenoids small, the inter-arytenoid space marked; the vocal cords appear thin; posteriorly in the posterior commissure the mucous membrane is white and thickened. On phonation this thickening is squeezed into a ⌒⌒ shaped protuberance of about 1 to 2 mm. in thickness. This ⌒⌒ shaped form is due apparently to fixation of the mucous membrane centrally to a median raphé. When ulceration occurs it begins, as a rule, at the bottom of this central or fixed portion.

The condition found when the above laryngeal conditions caused by pulmonary tuberculosis are complicated by the presence of a sinusitis are as follows: The pallor and lack of reflex sensibility of the mucous membrane of the palate, pharynx, and larynx are retained. The naso-pharynx contains pus or infected mucus, which is not infrequently seen under the middle turbinate of the affected side, but cannot be observed by anterior rhinoscopy, the nose appearing normal except for a pallid and thin mucous membrane. The oro-pharynx shows a network of blood-vessels, between which the mucous membrane shows a pale velvety swelling. The larynx is pale, the mucous membrane covering the arytenoids shows pallid thickening, and the inter-arytenoid space is diminished or absent. The mucous membrane of the arytenoid region tends to form an oblong bar, smaller than that met with in sinusitis without pulmonary tuberculosis, and the forward prolongation met with in that disease is more marked, and not infrequently overhangs the larynx. The mucous membrane of the trachea is thin, and the rings are plainly seen. The tonsils are small and pale; any enlargement is generally of the lower pole.

Diagnosis.

1. *Pulmonary Tuberculosis.*—The thinness, pallor, and lack of reflex sensibility of the mucous membrane, larynx, pharynx, and soft palate are so rarely absent in the earlier stages of pulmonary tuberculosis that they should be considered with the remainder of the facts in establishing a diagnosis of this complaint. The following case is instructive:—

Case 1.—Male, aged 28, admitted to sanatorium for hæmoptysis on five occasions during the last ten years. Physical signs in chest reported as slight, tubercle bacilli never found. He consulted me for enlarged tonsils, removal of which had been recommended by his doctor. Both tonsils were large and the mucous membrane of the larynx and pharynx thick and red. The balance of evidence seemed against a diagnosis of pulmonary tuberculosis; I therefore estimated the time of blood-clotting, which on three examinations on different days averaged 32 minutes. Closer investigation of history and physical signs showed the condition to be sinusitis complicating hæmophilia.

2. *Sinusitis.*—Patients with rhinitis or rhinitis with sinusitis complain of nasal obstruction; those with obstructive sinusitis complain of pain. In patients having well-marked sinusitis with only slight inflammation of the visible nasal mucosa the pus finds its way into the naso-pharynx, and thence to the laryngopharynx, from whence it is coughed up. If the degree of obstruction to the outflow of the affected sinus is slight, pain is absent; the patient is not infrequently unaware of the nasal discharge, and seeks advice for a chest condition. Diagnosis rests primarily on the presence of pus, which can be seen dropping from behind the soft palate. This flow of pus is frequently intermittent. Where a network of enlarged venules is seen on the posterior wall of the oro-pharynx a focus of infection will nearly always be found in the teeth, in the nasal passages, or in both. The chest condition cannot be regarded as connected with a nasal infection unless a history of post-nasal discharge can be elicited, or unless pus can be seen in the naso-pharynx or the posterior portion of the nose. This pus generally originates in the sinuses, but it may also be due to conditions in the naso-pharynx, such as suppurating adenoids, or to an enlargement of the visible nasal mucous membrane with an increase in number of the mucous glands. The commonest sinus infection met with in chest conditions is that of the maxillary antrum; this is frequently secondary to a dental condition. It is rare to meet with maxillary sinusitis due to dental conditions unless the nerve of the offending tooth is dead. If an abscess at the apex of the root of a tooth ruptures into the antrum, the pain in the tooth ceases as soon as the pus is no longer under pressure. When chronic post-nasal discharge is present, crowned and other dead teeth should be X rayed and, if necessary, extracted. The existence of sinusitis of the anterior group may be regarded as probable if pus can be seen by posterior rhinoscopy in the posterior part of the middle meatus, and as still more probable if pus is washed out from beneath the middle turbinate by means of liquid paraffin introduced through a ureteral catheter. If after washing out of the middle meatus pus is found on washing out of the antrum, the case is one of maxillary sinusitis; but if no pus is found in the antrum the presence of pus beneath the middle turbinate points to ethmoidal or frontal sinusitis. Frontal and anterior ethmoidal sinusitis do not complicate the diagnosis of chest conditions, because pain is always present in these conditions, and attention is early attracted to the nasal condition. Posterior ethmoidal and sphenoidal sinusitis have been met with in conjunction with infection of other sinuses, but not otherwise. The presence of pus in the superior meatus, or between the middle turbinate and the septum, suggests the diagnosis, which is confirmed by the removal of pus from the sphenoidal sinus by lavage.

Treatment.

The treatment of sinusitis without tuberculosis follows the usual lines and calls for no comment. It is becoming more generally recognised that many cases of chronic bronchitis have their origin in an infection of the accessory sinuses. The treatment of sinusitis complicating pulmonary tuberculosis involves a consideration of very complex pathological processes. Tubercle bacilli shut off from the general bloodstream in miliary tubercles produce toxins which, passing into the general circulation, cause antitoxins to be formed, and an antitoxic balance is produced. Few antibacterial substances are produced, and the tubercle bacilli continue to live, but not to multiply unless some change in their environment takes place.

Micro-organisms in the sinuses continue to multiply and secrete toxins, which being absorbed by the mucous membrane produce antitoxins, and an antitoxic balance is produced. The bacteria in the sinuses do not reach the blood-stream; hence few, if any, antibacterial substances are produced. The presence of toxins within the nasal passages produces a reaction within the mucous membrane which may remove the bacteria, but the existence of a chronic sinusitis is evidence that the bacteria have not been removed, but that they have adapted themselves to their altered environment, in which process they generally become diminished in virulence, so long as the environment is not again altered. Any alteration of environment tends to alter this virulence, and if there is for any reason an increased absorption of toxin above that against which the body is protected, it upsets not only the antitoxic balance of that micro-organism, but also that of the tuberculous infection and a flare-up of the tuberculous processes results. It is, therefore, of paramount importance to immunise the patient to a high degree against the nasal infection and guard against development of micro-organisms within the sinuses by packing these where possible with some antiseptic of prolonged action, such as iodoform emulsion. In general, patients with tuberculosis of the lungs should be operated upon under local anæsthesia, lest a bronchitis or pneumonia resulting from the inhalation of the anæsthetic activate the pulmonary tuberculosis.

Case Notes.

The following cases well illustrate the simulation by sinusitis of pulmonary tuberculosis:—

Case 2.—Male, aged 28, examined on July 17th, 1919. Area of cardiac dullness and heart sounds normal. Pulse 80–120–80 good. Lungs: Harsh breathing right apex, expiration prolonged, occasional crepitations heard. Diagnosis pulmonary tuberculosis.

On Feb. 24th, 1921, tuberculosis dispensary states "unable to work 13 weeks." On April 22nd general condition fair, tongue clean, teeth fair, heart sounds normal, pulse 72–120–84 tolerance fair: arrhythmia after exercise. Lungs: retraction both apices, dullness right, occasional crepitations right apex, a few moist sounds at both bases. Abdominal splashing. Examined at dispensary on March 6th, 1922. Weight 114 lb.; teeth bad, slight retraction apices, no definite dullness. Expiratory murmur at right upper lobe, harsh breath sounds at left upper lobe. On March 5th, 1923, weight 116 lb., heart normal, no loss of resonance, well-formed chest, no active signs of pulmonary tuberculosis.

Admitted to hospital for observation on April 19th, 1923. Complained of cough, expectoration, and giddiness. Chest emphysematous, hyper-resonant except right apex, no adventitious sounds, urine normal, weight in clothes 113 lb. Sputum 11 times negative for tubercle bacilli, complement-fixation test positive, Wassermann reaction negative. X ray screen; lungs clear up well, diaphragm excursion 1½ each side. Plate, nothing of note detected. Physician reported: "I cannot find any evidence of pulmonary tuberculosis." Laryngologist reported: Right maxillary sinusitis with laryngeal and tracheal changes secondary to this." Sputum examined microscopically showed many epithelial cells and polymorphonuclear leucocytes. Exercise temperature tested daily for three weeks rose at times to 99°; pulse, on one occasion 90, averaged 70.

CASE 3.—Male, aged 32, examined on Feb. 23rd, 1918. Chest flattened, apices shrunken, impaired resonance, roughened breathing right apex, marked venous hum at root. Husky voice, occasional night sweats; vocal fremitus increased over right apex; has lost 2 st. in weight. Diagnosis, pulmonary tuberculosis.

On Oct. 14th slight sticky rhonchus heard at right apex behind. Chest: expansion 32½–35. Weight 146 lb.; stated, "No cough or sputum." On August 9th, 1919, patient felt about the same; well-nourished, healthy, weight 152 lb. stripped; expansion 32½–35½, right less than left; flattening below both clavicles. No physical signs of active disease. Vocal resonance increased right apex. Diagnosis, pulmonary tuberculosis (quiescent). On Sept. 28th, 1920, stated "about the same"; much cough and phlegm, no blood. Chest expansion 2 inches; flattening both apices. Percussion normal both apices. Bronchial breath sounds left apex. Râles and rhonchi numerous left apex. Heart and nerves normal. On August 18th, 1921, fat and flabby. Lungs: Marked flattening both apices. Expansion 2¼. Percussion note dull, both apices and right base. Breath sounds harsh, no adventitious sounds. Heart nil. Pulse-rate 84; nervous system nil, except tremor of hands. On Sept. 10th, 1922, stated "about the same." Still very fat and flabby. Pulse weak but regular. Right apex percussion note dull. Breath sounds harsh. Breath sounds weak behind in right lung. Right lung, movement less than left. Fine wheezing at right apex, left lung, heart, and nerves nil.

On March 21st, 1923, admitted to hospital for observation. Complained of breathlessness after exertion, slight cough, and frothy phlegm. Heavily-built, chest wall thick. No adventitious sounds or abnormal physical signs detected in chest. Urine normal. Weight 190 lb. in clothes. Average temperature, A.M. 97·2°, P.M. 98·2°; average post-exercise temperature 98·4°; average post-exercise pulse 78. Tubercle bacilli absent. Complement-fixation test negative, Wassermann reaction negative. X ray report: Screen, lungs clear up well; diaphragm excursion right 2½, left 2. Plate showed nothing of note. Physician reported: "I cannot find any evidence of pulmonary tuberculosis." Laryngologist reported: "The nose, naso-pharynx, and larynx show changes secondary to the left maxillary sinusitis which is present, also ? right maxillary sinusitis."

Patient discharged from hospital on the same day.

Prognosis.

From the examination of something over 100 cases of tuberculosis without sinusitis, and about the same number of cases of tuberculosis with sinusitis, I am convinced that from the above signs no conclusion can be drawn as to the activity of the pulmonary tuberculosis. I have reached this conclusion on account of two classes of case—one in which pulmonary tuberculosis had been apparently inactive for periods varying between two and four years, sinusitis not being present, but in which the pallor and lack of reflex sensibility were still marked; the other in which pulmonary tuberculosis as judged by physical signs, absence of tubercle bacilli, &c., was inactive, but in which an active sinusitis was present and loss of weight continued. The condition of a sinusitis without pulmonary tuberculosis gives rise to bronchitis. To what extent such a condition, when active for several years, can shorten life is in the present absence of statistics a matter of surmise only. In general the observations I have made point to a continuance of the condition, with resultant damage to the bronchial mucous membrane of more or less severity, until other factors increase the acuteness of the sinusitis and cause pain and nasal discharge, thus revealing the cause of what has previously been treated as an affection originating in the chest.

THE INCIDENCE OF MALIGNANT DISEASE IN THE APPARENTLY BENIGN ENLARGEMENT OF THE PROSTATE.*

BY R. H. JOCELYN SWAN, M.S. LOND.,
F.R.C.S. ENG.,
SURGEON TO THE CANCER HOSPITAL, BROMPTON.

I WOULD like at the onset to make a clear definition of the point that I wish to raise; I wish to discuss, not those cases of prostatic enlargement which are obviously carcinomatous or even suspicious of carcinoma when they first come under the notice of the surgeon, but rather those cases which clinically present all the features of the ordinary simple prostatic enlargement, and which are operated upon as such, but in which, owing to some unusual feature in the operation or on subsequent microscopical examination of the organ removed, malignant disease is found as an unsuspected complication. Four such cases have recently come under my observation, and I therefore bring the subject forward for consideration in the hope that some points which have escaped me may be elucidated and may assist in correct diagnosis before operation is advised.

Thus I eliminate at once those cases of alteration in micturition with difficulty, frequency, and perhaps hæmaturia which on rectal examination present a firm, inelastic or nodular swelling of the prostate, with fixation or lateral infiltration in the pelvic lymphatic areas, and confine myself to those cases in which the digital examination of the prostate per rectum shows a soft, elastic, movable enlargement of the gland of uniform consistence, which has been looked upon as the type of enlargement variously spoken of as adenomatous, cystic adenoma, hyperplasia, or as chronic lobular prostatitis.

Case Records.

Perhaps it would be best at this stage to give a brief note of the cases upon which my remarks are based:—

CASE 1.—The patient, aged 75, commenced to have trouble with increasing frequency of micturition about five years ago, progressing gradually until it amounted to every hour by day and about five times at night, with occasional involuntary dribble. He had to strain to micturate, but there was no pain, no backache, and no increased thirst. No hæmaturia.

---

* A paper read at the Urological Section of the Royal Society of Medicine, May 31st, 1923.

Condition on Examination.—A rather feeble old gentleman. Pulse 76, vessels slightly thickened. Blood pressure 160 mm. Neither kidney nor liver was palpable; bladder was not felt distended. Urine passed in forceless dribble, clear, acid, sp. gr. 1021, no albumin or sugar. Urea 2·3 per cent. Catheter passed easily; residual urine 3½ oz. Per rectum, prostate uniformly enlarged, smooth, elastic, and movable. Easily felt bimanually.

Operation.—On July 20th, 1921. The prostate projected into the bladder as an apple-like swelling, smooth, and elastic. Enucleation was easy, though there was some increased fixation in the posterior part of the gland. On subsequent examination with the patient in the Trendelenburg position and the cavity illuminated, two small firm nodules were found in the posterior part of the prostatic cavity and were removed.

The prostate removed appeared to be of the ordinary fibro-adenomatous type, but it was rather ragged on the posterior aspect. On microscopic examination of this portion of the gland, and also of the small nodules removed from the posterior part of the cavity, adeno-carcinoma was found to be present.

Course of Case.—When seen again four months later, patient looked well and passed urine comfortably and with good stream. Frequency five times in day and once at night. A 14 steel sound passed easily, but there was a feeling of roughness in passing through the prostatic area, like rubbing against wet wash-leather. Per rectum the prostatic area was small, but there was a firm band of infiltration as thick as the forefinger, passing outwards and upwards on the right side, in the area of the pelvic lymphatics. No glands were felt. The patient died on August 17th, 1922, 13 months after the operation. from progressive weakness, but Dr. G. S. Hovenden wrote that at no time had he the slightest difficulty in passing a full-sized catheter. No post-mortem was obtained.

Case 2.—Major A., aged 61, was seen with Dr. W. W. Shackleton on Dec. 1st, 1922. In December, 1919, he consulted his doctor owing to the occurrence of a blood-stained emission; he was then found to have an enlarged prostate, and on catheterisation was found to have residual urine. From this time he had increasing trouble in micturition, hesitation, and frequent desire. In September, 1921, he had acute retention, requiring catheterisation. Frequency gradually increased to two-hourly day and night, and a month ago his doctor found his urine very purulent and the bladder considerably distended. He had no backache, but marked thirst and loss of appetite. Had never seen blood in the urine.

Condition on Examination.—Thin, with flushed cheeks. Arteries thickened; blood pressure 170 mm. Tongue dry and brownish. The urine passed was turbid with pus, alkaline, sp. gr. 1004, and albumin was present. The bladder remained distended to within 1 inch of the umbilicus after micturition. Neither kidney was palpable. Per rectum the prostate was enlarged, flat, smooth, elastic, and readily movable. Blood urea was 72 mg. per 100 c.cm.

On Dec. 7th, 1922, a Pezzer tube was passed into the bladder above the pubes under local anæsthetic. On the following day the urea-concentration test only showed a percentage urea of 1·5 and 1·6 in the second and third hours. On the 17th blood-urea had fallen to 38 mg. per 100 c.cm. and urine urea concentrated to 2 per cent. and 2·2 per cent. in the second and third hours.

Operation.—Prostatectomy on the 19th. Enucleation was easily carried out except in the upper and posterior part, where the gland was adherent. The gland was of moderate size and showed many adenomatous, rounded masses, but was lacerated on the posterior aspect. Dr. H. J. B. Fry reported that the glandular structure showed irregular invasion of the surrounding tissue with loss of basement membrane and irregular mitoses, indicating adeno-carcinoma. This opinion was confirmed by Dr. S. Wyard.

Course of Case.—Except for some trouble from hæmorrhage on the fifth day, the patient did well and was healed, and passing urine naturally, on Jan. 5th, 1923. On Feb. 14th he looked well and tongue was clean and moist. A catheter was passed easily. Per rectum the prostatic area was soft, but there was some thickening in the left pelvic lateral space, suggesting commencing infiltration of the lymphatic area.

Case 3.—The patient, aged 62, had had trouble with frequent micturition and slow forceless stream for four years, gradually increasing until three weeks ago, when he had acute retention, for which a catheter was passed. Again retention nine days ago, since when a catheter has been passed twice a day; he only passes a few drops of urine per urethram when straining at stool. No hæmaturia; no backache or thirst.

Condition on Examination.—A thin, hard-working man. Arteries thickened. Tongue moist and clean. Neither kidney nor liver felt. Bladder distended to 2 inches above the pubes. Catheter passed and 20 oz. of urine drawn off, hazy, acid, sp. gr. 1016, albumin present. Per rectum the prostate was enlarged, smooth, elastic, but firm; the left side was larger than the right. The gland was movable and could be felt bimanually.

Operation.—On June 28th, 1921, the left lobe of the gland was enucleated with great ease, but the right was somewhat adherent in the lateral aspect. On subsequent examination this surface was found to be ragged, though the whole appeared to be the usual soft so-called adenomatous enlargement. Microscopic examination by Dr. G. L. Eastes showed, however, active adeno-carcinoma, consisting of polyhedral cells arranged in primitive glandular form.

Course of Case.—Patient did well after operation, and the wound closed in 20 days. During convalescence a tube of radium was passed into the prostatic cavity and allowed to remain in situ for four hours on alternate days for six applications. Six months later patient was passing urine with good force, but the frequency had increased to three-hourly by day and twice at night. No straining. Urine clear and free from albumin. He complained of aching in the right sacro-iliac and right sciatic areas. Glands could be felt to be enlarged in the right iliac fossa above Poupart's ligament, and on rectal examination there was a hard, nodular infiltration in the right lateral pelvic lymphatic area. The patient lost weight rapidly, though he had no further difficulty in micturition, and died in February, 1922, eight months after operation.

Case 4.—The patient, aged 78, was seen, with Dr. C. E. Sparks, on April 15th, 1922. He had had increased frequency of micturition for about five years, chiefly during the day, with feeble, forceless stream. No pain. On 13th he had acute retention and his doctor could only pass a No. 6 catheter with difficulty. The next day, the retention remaining, no catheter could be passed, and he was in considerable pain from distension of the bladder, with overflow dribbling of urine.

Condition on Examination.—His tongue was dry and glazed. He had bilateral backache and marked thirst. The bladder was very distended and tense. Per rectum the prostate was found to be enlarged, soft, uniform in consistence, and movable. Attempts at catheterisation failed, a stricture and false passage being present in the bulbous urethra. A small tube was passed into the bladder above the pubes and the urine slowly drained off. The urine was blood-stained, sp. gr. 1012, and contained albumin but no sugar. Ten days later his tongue was moist and clean, thirst had gone, and the urine was clear. The blood-urea was 41 mg. per 100 c.cm., but there was no test previous to the vesical drainage for comparison.

Operation and Course of Case.—Under an anæsthetic the stricture was divided and the suprapubic incision was enlarged. The prostate was projecting into the bladder in bilateral form and was easily and rapidly enucleated. The gland showed the usual rounded fibro-adenomatous masses, but it was noted that the right lobe was more dense than the left and was slightly reddened. Pathological examination by Dr. Eastes showed that there was undoubted carcinoma present in a small area in the centre of the right lobe. The patient made an excellent recovery from the operation, but died subsequently from diabetic coma.

I would like to mention another case (for the notes of which I am indebted to my colleague, Mr. Perciva Cole), though I do not include it in my series.

Case 5.—This patient, aged 75, was operated upon in 1917 for an apparently simple prostatic enlargement, having had prostatic symptoms for three years and for the three weeks previous to operation complete retention requiring catheterisation. The prostate was enlarged, smooth, and elastic, and looked upon as adenomatous. It was easily enucleated and the pathological report returned as adenomatous, though it does not appear that any microscopic section was made. In February, 1923, he was again admitted to hospital owing to difficulty in micturition. Frequency was increased to every half-hour during the day and four to five times at night with great straining. No catheter could be passed, each being arrested in the prostatic urethra. Under spinal anæsthesia a filiform bougie was passed with difficulty and the firm tissue in the prostatic area incised with an internal urethrotomy knife. This was followed by rigors and hyperpyrexia, sweating, and death after 19 hours. At the post-mortem the whole of the prostatic area was found to b occupied by firm hard tissue, which proved on microscopic examination to be spheroidal-celled carcinoma. There was glandular infiltration in the iliac and lumbar glands, but no evidence was found of visceral metastases. This case is very similar to the one reported by Mr. R. Thompson at the last pathological meeting of the Section of Urology of the Royal Society of Medicine.

Analysis of Cases.

Analysing the records of these cases, it will be seen that they present the usual train of symptoms spread over some years of gradually increasing difficulty and frequency of micturition associated with the ordinary benign prostatic enlargement, and that clinical examination of the prostate by digital palpation per rectum failed to convey any suspicion of malignant disease. It was only at the operation for removal of the gland that any difference from the usual simple enucleation was found, when subsequent microscopic examination revealed the presence of carcinomatous infiltration in the area in which some fixation of the gland occurred to the surrounding "capsule." In the first three cases the operation was followed by carcinomatous infiltration in the lateral pelvic lymphatic space which was certainly not present before it. It is a noteworthy fact, however, that micturition was able to be performed freely even when this recurrence was well established. In one case the enucleation presented no difficulty from fixation and subsequent microscopical examination revealed a small central focus of malignant disease in one lateral lobe, this finding being even a greater surprise than in the cases in which some capsular adhesion had been found. I am of the opinion that this condition happens more frequently than may be supposed, and is an indication that every gland removed at operation must be submitted to a close microscopical examination before it can be pronounced wholly innocent. In each case the average length of history given by the patient before seeking advice was about four years, so that the progress of each case cannot be looked upon as any more rapid than the ordinary benign prostatic enlargement; neither pain nor hæmaturia had been a feature in any case.

I must confess that in many cases of prostatectomy the macroscopic appearance of the gland removed has given rise to no suggestion of malignancy, so that in a large number of my cases no critical pathological examination has been made. Since I have become aware of the possibility of unsuspected malignant disease being present, however, I have had each gland examined, and I find that these cases form four in a total of 28 consecutive prostatectomies, or roughly 14 per cent. Owing to my failure to have all the glands examined previously to this series, figures from my former series of cases would not be reliable. I have, however, enlisted the services of Dr. Eastes and Dr. C. Fletcher, and I have their permission to make use of the following figures. In a series of 678 prostates removed by operation and submitted to them at the Laboratories of Pathology and Public Health for pathological examination during the last ten years, no less than 174, or 25·7 per cent., were definitely malignant, whilst they classify 58 others, or 8·6 per cent., as border-line or pre-cancerous; 443, or 65·3 per cent., were innocent (adenomatous), and 3, or 0·4 per cent., were tuberculous (Table I.). Dr. Fletcher adds the following criticism of these figures:—

Table I.—*Prostates Removed by Operation during the Last Ten Years and Submitted to Pathological Examination at the Laboratories of Pathology and Public Health. Figures given by Dr. G. L. Eastes and Dr. C. Fletcher.*

		Per cent.
Definitely malignant	174	= 25·7
Border-line cases (pre-cancerous) ..	58	= 8·6
Innocent (adenoma)	443	= 65·3
Tuberculous	3	= 0·4
Total ..	678	

> "I think the findings, however, must be discounted to some extent by the fact that many surgeons send for examination only those prostates about which they themselves have doubt and destroy the others. On the other hand, in the vast majority of these prostates, only certain parts have been cut and not complete cross-sections of both lobes—in fact, in many cases I only received a piece of the organ. This would militate against the other factor, but I think not to the same extent, and I consider that the percentage of malignant prostates given by these figures is higher than it would be if all prostates removed were examined. Those classified as pre-cancerous are border-line cases about which pathologists might well differ, and I should think most are innocent."

These figures and Dr. Fletcher's remarks upon them are very valuable, representing as they do the microscopic findings in prostates removed by operation in the practice of a large number of surgeons; but, as he justly remarks, the incidence of carcinoma in 25·7 per cent. is probably higher than the true proportion. I think, however, that we may with fair justice assume that the operation for the removal of the gland in the very great majority of these cases was performed under the diagnosis of a simple enlargement of the organ, though I know that I for one have not sent him many that I have removed, because I thought the naked-eye appearance was conclusive that the tumour was innocent, an error now rectified.

Findings of Other Investigators.

H. Wade, of Edinburgh, in 1914 found that in a series of 134 specimens of enlarged prostates, 14 were carcinomatous. Of these 14 cases, 10 were removed by operation and were similar to the cases I have described—namely, that they were removed under the assumption that they were benign tumours and only found to be carcinomatous on subsequent microscopic examination. He states that, in these cases, the carcinoma commenced in the centre of an area of chronic lobular prostatitis (by which term he describes the common adenomatous enlargement), remarking that by this fortunate circumstance enucleation is at first easy. I would remark that in three out of four of my cases the malignant disease appeared to commence in the periphery of the gland and in only one in the centre. Wade further emphasises the necessity of obtaining complete sections of the whole gland before an opinion can be expressed upon the existence of early carcinoma. He is of the opinion that the malignant change occurs in a gland that has already undergone enlargement by innocent "hypertrophy."

Wilson and McGrath in 1911 noted that carcinoma may be found in a prostate removed by operation for apparent benign enlargement, and remark that the malignant focus appears to commence in an area of prostatic enlargement. At the meeting of the International Urological Congress, held in London in 1911, a long discussion took place on the ultimate results of prostatectomy. In the report of the various papers there submitted I am unable to find any definite record of the finding of carcinoma in the apparently benign enlargement. Hugh Young, in a series of 450 cases operated upon by him, gives no record of any found to be malignant, but quotes some cases in which, as the result of operation, the urinary obstruction was not completely removed or partially returned. Most of these cases improved after second operations, but some may have been unsuspected carcinoma. Proust, Zuckerkandl, Thomson Walker, and Cuthbert Wallace in the same discussion make no reference to malignant disease. Fullerton, of Belfast, mentions two cases in which the firmness of the gland on rectal palpation gave rise to a suspicion of malignant disease, and in both the microscopic examination proved this to be present, but neither could be called unsuspected. Marion, Casper, and Pasteau also do not refer to it.

A serious note of the condition was brought out by Sir John Thomson Walker in an address on Some Problems of Prostatectomy, delivered before the Harveian Society in November, 1922,[2] where, in discussing the advisability of operation in early cases, he gave as a reason for this that malignant changes may occur in a prostate the seat of simple benign enlargement. He states that it may occur at the periphery of one lobe as a localised firm, inelastic area, which at operation strips with difficulty, or that it may occur in the centre of a lobe that has shelled out readily at the operation. In a series of 100 consecutive cases of prostatectomy for apparent simple enlargement by Sir John Thomson Walker, no less than 16 were found by the pathologist to show areas of carcinomatous change. In 11 of these 16 cases there was nothing in the clinical examination to suggest malignancy in any form; in four there was a small firm area on one side and in one the prostate was somewhat firm in consistence. These figures are of the utmost importance; if the combined figures reported by Wade, by Thomson Walker, and those reported above by me be added together it gives a total of 34 cases of unsuspected carcinoma out of 262 cases in prostates removed by operation for apparent benign enlargement in three series of consecutive cases without selection, or a percentage rate of nearly 13—a sufficiently large proportion to carry in one's mind when discussing with a patient the necessity of early operation and in outlining the prognosis after operation in these cases (Table II.).

Pathological Considerations.

In putting these remarks before you, I have tried to refrain from any discussion on the true pathology of the enlarged prostate, and only do so at this stage to draw a certain analogy with the types of carcinoma seen in other organs of the body. The senile enlargement of the prostate has been termed by different pathologists adenoma, cystic adenoma, simple hyperplasia, chronic lobular prostatitis, and interstitial prostatitis, and as far as I can gather they have not yet made up their minds as to which class it is to be labelled. Pathologists are not the only people in doubt about the prostate, for surgeons still seem to be divided in their opinion as to whether the operation of prostatectomy is to be regarded as a complete enucleation of the whole gland or as the removal of adenomatous masses from a false capsule formed of compressed prostatic tissue. Without venturing upon any decided opinion on these vexed questions, which might in these days of prostatic surgery change the forcible opinions expressed in the earlier days, my motive this evening is to direct your attention to the comparative frequency with which carcinoma may exist as a small undetected focus in a prostate which is the seat of senile enlargement. The analogy which I wish to make is that between these cases and those of carcinoma in other glandular structures in the body. In the breast, in the tongue, the stomach, and the intestine, as well as in other organs, the opinion has been expressed that carcinoma may occur in areas which have been the seat of simple chronic inflammation or of ulceration. May not the same sequence occur in the prostate, and thus carcinoma commence as a focus in a gland already the seat of the benign enlargement?

I wish to take this opportunity of thanking Dr. Eastes and Dr. Fletcher for the trouble they have taken in obtaining the figures relating to pathological examinations carried out at the Laboratories of Pathology and Public Health.

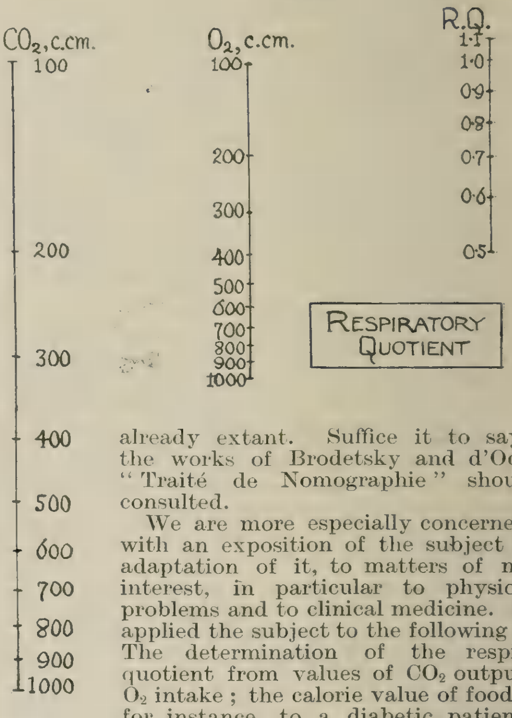
DONATIONS AND BEQUESTS.—The late Mr. J. Bright James, of Hartley, near Plymouth, left by will £1000 to the South Devon and East Cornwall Hospital; £1000 to the Royal Albert Hospital, Devonport; £1000 to the Blind Institution at Plymouth, and £1000 to the Blind Institution at Devonport.—By the will of the late Mr. William Tozer, of Tapton Edge, Sheffield, the testator left £500 to the Royal Infirmary, Sheffield; £500 to the Royal Hospital, Sheffield; £500 to the Jessop Hospital for Women, and £500 to the Children's Hospital, Sheffield.—Under the will of the late Mr. Joseph Taylor, of Balls-road, Birkenhead, Cheshire, the Birkenhead Borough Hospital will receive £250 and the Birkenhead and Wirrall Children's Hospital £200.

APPLICATIONS OF NOMOGRAPHY TO MEDICINE.

BY W. A. M. SMART, M.B., B.S., B.SC. LOND.,
DEMONSTRATOR IN PHYSIOLOGY AND PHARMACOLOGY, LONDON HOSPITAL.

NOMOGRAPHY is now so well established that few words of introduction are necessary. There are many formulæ in physics, engineering, and aeronautics in which three or more variables, or powers of variables, occur. In the ordinary way, space of three or more dimensions would be required for their representation, and this in many cases would be inconvenient or even impossible. Nomography is a geometrical device whereby the relation between any number of such variables may be represented graphically on a plane surface such as a sheet of paper. There is no division into squares, but merely a set of lines, which may be straight or curved, parallel or not, as the case may be. The lines are suitably graduated, each according to one of the variables, and the relation between these variables is such that a straight line can always be drawn through corresponding quantities. It is not proposed to enter here into an account of the method of determining the graduations, the position of the zeros of the scales, or their relative distances apart. This must be sought in the books and literature already extant. Suffice it to say that the works of Brodetsky and d'Ocagne's "Traité de Nomographie" should be consulted.

FIG. 1.



We are more especially concerned here with an exposition of the subject in my adaptation of it, to matters of medical interest, in particular to physiological problems and to clinical medicine. I have applied the subject to the following cases: The determination of the respiratory quotient from values of CO$_2$ output, and O$_2$ intake; the calorie value of food given, for instance, to a diabetic patient, and consisting of various weighed amounts of protein, fat, and carbohydrate; the calorie value per kilo body-weight; and the determination of pH value from a knowledge of the hydrogen-ion concentration. The Du Bois formula connecting surface area, body-weight, and height has already been nomographically demonstrated by Feldman and Umanski.[1]

The Respiratory Quotient.

The vertical line on the left (Fig. 1) is graduated logarithmically from above downwards to represent c.cm. of CO$_2$ exhaled, while the centre line, likewise graduated downwards, is only half the scale of the former and represents the number of c.cm. of oxygen taken in. The line on the right-hand side gives the value of the R.Q. All one has to do is to take a straight ruler or thread, place one end over the number of c.cm. of CO_2 exhaled by the patient, join it to the c.cm. of O_2 inspired, and produce the line thus formed to the right-hand scale. The point of intersection with it immediately gives the required value of the R.Q. It will thus be seen that the matter is quite simple, once the scales have been accurately drawn. The chart may be conveniently pasted on cardboard, varnished, and hung up in the ward ready for instant use.

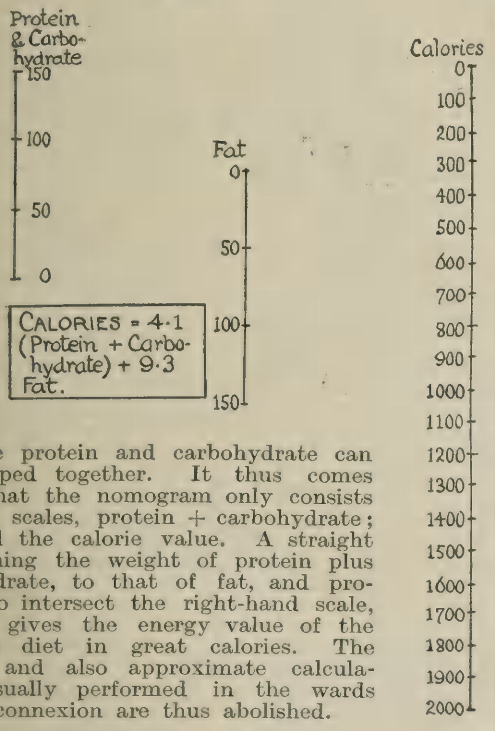
---

[1] THE LANCET, 1922, i., 273.

The Calorie Value of a Diet.

This is a rather more ambitious nomogram (Fig. 2), more factors being included, but it will be seen that if the scales are suitably drawn and adjusted, the matter is as simple as before. In theory we require a nomogram of the form $Q = aX + bY + cZ$. It is better adapted to our purpose to write $Q = pP + cC + fF$, where Q is the number of calories produced, P the weight in grammes of protein, C that of carbohydrate, and F that of fat. Each weight has now to be multiplied by the appropriate heat factor, $p = 4{\cdot}1$ for proteins, $c = 4{\cdot}1$ for carbohydrates, and $f = 9{\cdot}3$ for fats. Now this nomogram can be considerably simplified by the following considerations. The scales for the different food constituents can be each enlarged by 4·1 times, or 9·3 times the unit, as the case may be.

FIG. 2.



Also the protein and carbohydrate can be grouped together. It thus comes about that the nomogram only consists of three scales, protein + carbohydrate; fat; and the calorie value. A straight line joining the weight of protein plus carbohydrate, to that of fat, and produced to intersect the right-hand scale, at once gives the energy value of the patient's diet in great calories. The tedious and also approximate calculations usually performed in the wards in this connexion are thus abolished.

Calorie Value per Kilogramme.

In clinical work with diabetic patients it is necessary to know the calorie value of their diet per kg. of body-weight. For this purpose another nomogram has been designed (Fig. 3). The left-hand scale is total calorie value, the middle scale is body-weight, which may be in stones or in kg., and the right-hand scale gives the required calories per kg. It would be neater, perhaps, if this nomogram were combined with that of the calorie value of diets. There is no difficulty in so doing and a very comprehensive nomogram results. This means that, having determined by the ruler the total calorie value corresponding to the diet, we must look on the new scale for the same number denoting the value of the total calories. We then start a fresh line from this point, through the value of the body-weight of the patient, and produce it to cut the calorie-per-kg. line, thus giving the result required. As the weight of the patient is often measured in stones, it is convenient to graduate the weight scale in stones and in kg.

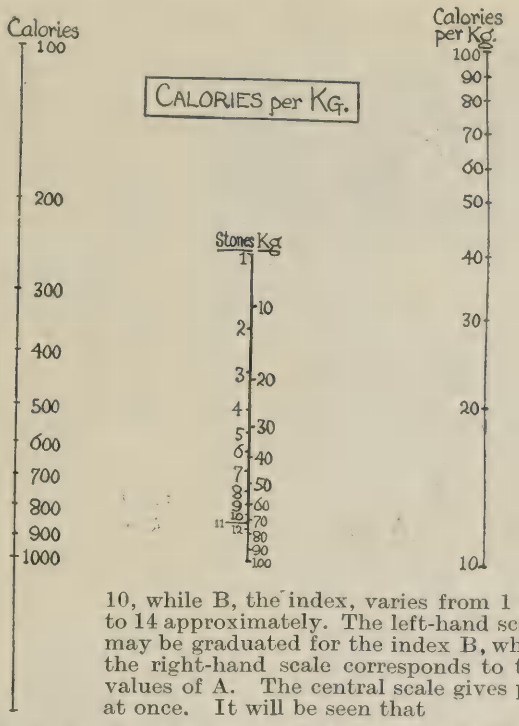
Hydrogen-Ion Concentration Values.

The formula for any hydrogen-ion concentration may be written $C_H = A\,10^{-B}$, where C_H is the concentration mentioned, A is a numeral between 0 and 10, while B, the index, varies from 1 up to 14 approximately. The left-hand scale may be graduated for the index B, while the right-hand scale corresponds to the values of A. The central scale gives pH at once. It will be seen that

$$pH = -\log C_H = -(\log A - B \log 10) = B - \log A.$$

Hence the nomogram is of the type $y = z - x$, showing that it can be plotted in the ordinary way—i.e., y as ordinate (giving pH), with x (i.e., log A) as abscissa, and z perpendicular to both. It is, of course, a plane. It is also clear that one might have put $y = 10^{-x}$ using semi-logarithm paper.[2] The above merely shows that it is just as readily adaptable to nomographic representation.

FIG. 3.



Percentages.

These may be easily determined nomographically. Such values are so often required in calculating statistics, and modifications can be made to suit any particular case.

What I have written probably suffices to show to what various cases the modern idea of nomographic representation may be put in the direction of physiological and medical science. There is no limit to the matter, beyond the fact that the quantities to be represented must be related to each other by some definite mathematical law. The great majority of such applications are fairly simple, the only difficulty being the setting out of scales, their distance apart, and their method of graduation. But such scales having once been made can be set up in block and reproduced indefinitely. The only real requisite is a straight ruler. The R.Q. chart, the total calorie value, and the calorie value per kg. charts are in constant use in the diabetic wards of the London Hospital. Copies of these nomograms may be obtained from Messrs. J. J. Griffin and Sons, Ltd., Kemble-street, Kingsway, London, W.C.

Clinical and Laboratory Notes.

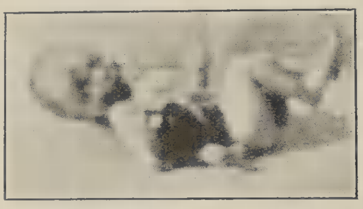
A CASE OF EXOMPHALOS.

By Frank Blake, M.R.C.S. Eng.

The following case of exomphalos is recorded as being of interest:—

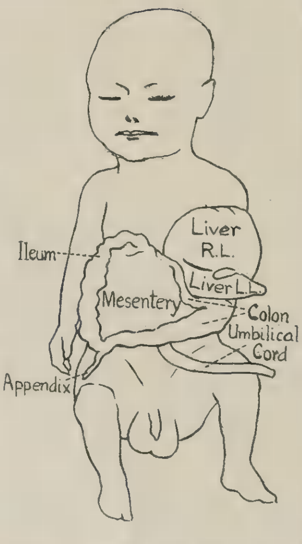
On June 24th, 1923, I was called to attend a primipara aged 31. I found that the membranes had ruptured prematurely, and that there was practically no dilatation of the os. The head was very high up, but able to pass the brim of the pelvis. By abdominal palpation I had already diagnosed a first vertex presentation. I left the case until the next morning, when I found that almost no progress had been made, and that the pains were very badly borne. I administered small doses of morphine and hyoscine subcutaneously, and waited. Late in the evening I saw the patient again and found that progress towards dilatation was very slight. The temperature had risen to 100·2° F. and the pulse-rate to 104.

Fig. 1.



Much against my principles, I decided to dilate the cervix manually and apply forceps. The fœtal heart was heard. I administered chloroform and proceeded. After traction (with Nevill's axis-traction handle on forceps) for about one and a half hours I delivered a full-term, plump but dead child with exomphalos, an abnormality I have never seen before. There was a defect in the middle line of the body from the umbilicus to the sternum, and the liver, gall-bladder, jejunum, ileum, ascending and transverse colons were outside the body cavity and merely covered with amnion.

Fig. 2.



The mother made an uneventful recovery without running any temperature after the day of delivery. The placenta was normal and quickly followed the child. The accompanying snapshot (Fig. 1) gives some idea of the condition. The dark object on the infant's right is the liver. Fig. 2 is a diagrammatic representation.

I find in Tweedy and Wrench, and also in the "Ten Teachers," only a few lines on this condition.

East Harling, Attleborough, Norfolk.

A CASE OF
OSTEO-ARTHRITIS IN CHILDHOOD.[1]

By Philip Weatherbe, M.B., Ch.B. Edin.,
Surgeon, Halifax Children's Hospital, Nova Scotia.

Osteo-arthritis in childhood is of interest on account of its rarity and doubtful pathology. Deformity may be prevented by timely splinting of the affected joints in their most useful position, and the cause should be sought early and removed if possible. Such cases, if left to continue without treatment, become very grave.

A well-nourished girl, aged 4, was admitted to hospital with a chronic crippling deformity of the joints, having been bedridden since the deformity began at 18 months of age.

History.—The condition began gradually at 18 months of age by left elbow becoming tender and painful and the child restless and fretful. After the condition persisted for three weeks a physician saw the child for the first time and he thought an injury had occurred to the elbow, but after an X ray examination the diagnosis still remained doubtful. Shortly after this the knee-joints became swollen and painful, followed by the other joints of the limbs. There were exacerbations of pain and swelling in the joints from time to time flitting from one joint to the other. The knees were always the most markedly affected and the most painful. The pain was severe enough to waken the child nightly, causing it to cry. The pain at night was present to some extent on admission. This child is the youngest of a healthy family of 11, who was first breast-fed and then bottle-fed until 13 months of age. The parents are healthy farmers, free from tuberculous or specific disease.

Condition on Admission.—Absolute ankylosis of left elbow-joint. Left wrist-joint swollen and stiff and impossible to dorsiflex, but easily flexed with no tenderness or pain in these two joints. Both knees flexed beyond a right angle and ankylosed in this position with swelling and slight tenderness. Both ankle-joints swollen and stiff with very limited movement. Other joints normal. General health good except for a chronic constipation.

The child had always been constipated, taking a mixture of Epsom salts and soda for months before admission, and cascara and liquid paraffin after admission to hospital. The diet has been liberal and nutritious, and there was no other history of disease.

General examination was conducted with the object of trying to find some focus of infection. A blood culture was negative. The blood was normal, so were the urine and fæces. The chest and abdomen revealed nothing by physical examination. Constipation was marked and the tonsils were under suspicion. X ray examinations of the joints revealed nothing definitely abnormal.

Treatment.—Treatment was based upon the possibility of infection from the tonsils and auto-intoxication from the bowel. The tonsils were removed, and a buried abscess found in one. The constipation was overcome with medicine—cascara 1 drm., liquid paraffin 1 drm.—night and morning. The pain was relieved by sodium salicylate ionisation. The joints were limbered up with sodium chloride ionisation, radiant heat, and massage, and the deformity corrected by forcibly breaking down adhesions under general anæsthesia and fixing the knee-joints in the corrected position by means of plaster of Paris. This operation was repeated on three different occasions with intervals between for massage and passive movement. After six months' treatment the child was able to walk with straight limbs partially movable, and with the full use of the left arm. The cause in this case is considered a combined one, an infection from abscess in tonsil and auto-intoxication from the bowel.

The result in this case up to the present has been satisfactory, but, as in other deforming diseases treatment should be maintained for months or years to prevent recrudescence, especially regarding deformity.

Venereal Disease in Western Australia.—In his report for the two years ending Dec. 31st, 1922, Dr. R. C. Everitt Atkinson, Commissioner of Public Health in Western Australia, states that the total number of new cases of venereal disease notified during the year 1921 was 1115, an increase of 132 upon the previous year. This increased incidence appears in the case of both sexes, 73 being males and 59 females; but whilst in the case of the former it represents an increase of only 8·4 per cent., in the case of the latter an increase of 50·8 per cent. is shown. The proportion of males to females affected was 5·3 to 1, as against 7·5 to 1 last year. It is probable, he points out, that this discrepancy represents, not an actual increase in the prevalence of venereal disease amongst the female population, but a greater willingness on the part of women to seek medical attention and an increasing knowledge of the subject and of the benefits to be derived from early recognition of the disease and early treatment of it. It is possible, he says, that the increase in tertiary cases is due directly to the more sensitive ice-box method of performing the Wassermann test having brought to light cases previously not diagnosed as syphilitic. Legal proceedings were taken against 24 persons consistently refusing to resume venereal treatment, 23 being males and one female. In ten cases a conviction was recorded. During 1922 the total number of new cases of venereal disease notified to the department was 727, which shows a reduction of 384 on the previous year. This reduction was evident in the case of both gonorrhœa and syphilis and in both sexes, and, provided it actually represents a diminished incidence, is extremely encouraging, justifying as it does the measures that have been adopted to cope with the problem of these diseases.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

INAUGURATION OF THE SECTION OF COMPARATIVE MEDICINE.

AT the first meeting of the new Section of Comparative Medicine on Oct. 24th Sir **CLIFFORD ALLBUTT**, President of the section, delivered the introductory address on the

INTEGRATION OF MEDICINE.

He said: If for years slowly and almost silently our work makes its way we must be content; our experience of the world teaches us to be content; but happily, now and then, after long hewing in the dark forest, we break into the light; we find ourselves almost suddenly upon a peak, our way open and bright before us, and our cause justified before man. Such a festival is our meeting to-day.

The barriers of convention, which ought to be slender and occasional, are of all the most inveterate and impregnable. Of such have been the barriers devised by mediæval perversities which, to its grievous injury, have split up medicine into fractions. As physic was divorced from surgery and mind from body, so the diseases of animals and plants were separated from those of mankind. The folly of the division of the medicine of the hand from the medicine of the bottle has now become so glaring that our next festival may be on the blowing up of this rampart; indeed, the gynæcologists have exploded their end of it already. But it is a big business to transform a mediæval castle, with its baileys, barbican, and keep, into a modern domain.

Let us rejoice then together that by the liberality, foresight, and generosity of the Royal Society of Medicine we are enabled to-day to celebrate the unity of medicine as a biological study. That you have made me your president on this memorable occasion, for in the history of medicine this day will take a memorable place, is a privilege for which I am deeply grateful to you. We have the mind of James Paget with us, and that of Sir John Bland-Sutton, happily still in the body, with us also. By him I have felt that this chair ought to have been occupied; for, while I have been talking about comparative pathology, he has been working in the field; but he has been called to a higher place, a distinction on which we all cordially congratulate him. For personal help in our campaign I should also like especially and gratefully to mention General Sir Frederick Smith, Prof. F. T. G. Hobday, Mr. W. M. Scott, of Bridgwater, and Prof. T. B. Wood, of Cambridge.

A Preliminary Survey.

I think you will agree with me that we must not swarm upon our new estate and try to do too much at first. If we do we may tire ourselves, overrun our work, and tread down our crops. Let us survey our ground carefully and make good by degrees. Many of our supporters are very busy men, and may be discouraged by too long papers or too many meetings; the secretaries will, I am sure, do their best to see that the papers laid before you are concise, relevant, and not too abundant.

Prof. W. H. Welch, of Baltimore, has written to me in these words: "Your first thoughts will be those of comparison"; to shed cross lights reciprocally from the pathology of one kind of living thing upon another, watching the variations of function in various biological systems. Consider, indeed, for a moment what, without the comparative method, would have now been the state of those other sciences which have worked by this method for many years past. Without the comparative method what of anatomy, or of anthropology, or of embryology; or what again of philology, of history, or even of theology? Without the method they would never have attained to the master conceptions which have lifted those studies from the plane of hobbies, or of literary amenities, or of mere erudition, to the rank of scientific ideas. Incidentally it is true that pathologists have already done much by their experimental researches—as into the properties of the cell, in the study of infections, and so forth—to gather in some comparative pathology, by parcels; but this is a straggling collection of knowledge; it gives us no general view of the whole, nor coördination of its parts.

Pathological Biology.

A certain portion of the time of this section will be devoted to the utilitarian side of our subject; to the study of the diseases common to man and animals—many of which may be carried by animals to man and conversely; to the ravages of disease in our herds and our crops; and, on the other hand, to the respective immunities and defences of plants and animals, as, for example, the immunity of the ox tribe to glanders, mentioned by Prof. Hobday at the Glasgow meeting of the British Medical Association, or again to our experience of anthrax serum; effective in man, in animals ineffectual, and again to the maintenance of the balances of species in the economy of nature. But, as I wrote in the *Times* in 1906 (June 5th), while not neglecting these instant needs we shall not permit our attention to be distracted from the pursuit of the larger and more disinterested researches; from a pathological biology which hereafter shall give us not only a control of several diseases, but an insight into large and fertile principles, foresights and controls over wide fields of nosology, interpretations of the various comings and goings of the manifold kinds of disease in all living things—plants and animals—of specific kinships underlying superficial differences, and of disorders of the more complex animals by the light of elementary changes in the simplest animals and in plants, in which the plasticity, I had almost said the pregnancy, of protoplasm shows us in manifold ways its marvellous endowments. We must have a keen eye to practice, whence, indeed, many of our most fertile problems arise, but we must aim also at the building up of the great principles upon which depends the practice of the future. I may recall the following reflection of the Agricultural Correspondent of the *Times* of 1906 (presumably Dr. Fream): "From a pathological point of view they (diseases of sheep) are a perfect mine of wealth, for they are fraught with scientific problems of the highest interest and importance, and are most suggestive of what may turn out to be a new light on the pathology of many of the contagious and infectious diseases of man and the lower animals." At this moment there appears in the Proceedings of the Royal Society (Ser. B, vol. xcv., p. 228, Sept. 1st, 1923) a very interesting study of that strange monstrosity achondroplasia. Few human achondroplastics manage to get born; of the few were a certain Egyptian god—who perhaps did not need a uterine phase—Æsop and Quilp. They are dwarfs with big heads and bodies, short arms and legs, and fin-like hands. Now Mr. Crew has illustrated the pathology of these monsters by certain monstrous calves of the Dexter breed, and postulates a perversion of the pituitary gland as the cause of the monstrosity. Moreover, he points out that this deformity may even shed some light upon the species problem.

I ought not to close an address, even so informal as this, without at least an allusion to the name of Pasteur, who threw open vast fields of comparative pathology; to mention the name of that great master is sufficient to turn your hearts silently to the centenary commemoration of that great man. I will conclude these remarks with the following quotation from another master of medicine, John Hunter: "In the course of a variety of experiments on animals and vegetables I have frequently observed that the results of experiments in the one have explained the economy of the other, and pointed out some principle common to both."

I now ask you to join me in wishing long life and prosperity to our new section. In Benjamin Franklin's now proverbial phrase, "Hard work is still the road to prosperity, and there is no other."

Cryptorchidism in Animals.

Prof. F. **Hobday** said he had chosen the subject of cryptorchidism partly because it was at least as common in domesticated animals as in man, and partly on account of his 30 years of experience in operating for this condition in animals. Human and veterinary surgeons, however, regarded this abnormality from different angles; the operative aim of the veterinary surgeon was to remove the hidden testicle in order to render the animal more docile and to do away with unpleasant characteristics of the uncastrated male. In animals the tendency to cryptorchidism was undoubtedly hereditary. This was well recognised by breeders as well as by veterinarians; the fault might even be transmitted to the second generation through a female. In addition to cryptorchidism, genuine cases of anorchidism and of monorchidism occurred in animals. Failure of the testis to descend might be due to abnormally short or abnormally long peritoneal attachments, to the unusual size of the testis or epididymis, which prevented its passage through the inguinal canal, or the canal itself might be narrower than normal. Finally, the gubernaculum testis might be paralysed or the skin of the scrotum so tight that when the testis had descended through the inguinal canal the organ was forced into an abnormal position under the skin of the prepuce, the abdomen, or the thigh.

In veterinary practice it was well established that when both testes were retained within the abdomen the animal was sterile, although spermatozoa were occasionally seen on microscopical examination. Sir John Bland-Sutton stated that after careful observations for many years of abdominal retention of the testes in man, he had only once found spermatozoa. In the horse in particular it was always advisable to convert the cryptorchid into a gelding on account of the treacherous disposition of these animals. Prof. Hobday gave an illustrated description of the actual procedure adopted which varied according to whether the testis lay in the inguinal canal or within the abdomen. In the latter case the abdomen itself was opened, the testis found and withdrawn by the hand. As the epididymis might be separated from the body of the testis by some distance, it was important to see that the former was not mistaken for the whole organ. In animals, and in the horse in particular, there was a wide range of abnormalities of the retained testis, ranging in size from that of a Rugby football to that of a walnut, and containing worms, cartilage, bones, and teeth and various kinds of tumour tissue. One case had been recorded in which the testis weighed 100 lb. A number of photographs of such abnormalities was exhibited by the epidiascope, illustrating the types commonly found in the horse, "dentigerous" and dermoid cysts containing hair being the most common. Very large cysts had to be ruptured before the testicle could be withdrawn from the abdomen. Other kinds of tumour tissue found were sarcoma, embryoma, fibroma, and lipoma; the latter was unknown in human testicular tumours, and the first of the kind reported. A specimen was also shown of a cyst of the testicle containing a worm (the *Strongylus edentatus*); a corresponding condition in man was the occurrence of living acari, *Histiogaster spermatagus*, in a cyst of the testicle. In other domesticated animals, except perhaps the dog, cryptorchidism was uncommon. A specimen of torsion of the retained testicle of the dog was exhibited. Prof. Hobday concluded by drawing attention to the fact that while testicular tumours and particularly dermoids were common in colts, he had never seen a dermoid cyst of the mare's ovary, and by emphasising the hereditary nature of cryptorchidism in animals. In both these respects animals differed from man.

Cryptorchidism in Man.

Mr. W. **McAdam Eccles**, who discussed abdominal retention of the testis in man, dealt first with the ætiology of the condition, and suggested that the failure of both testes to migrate from the abdomen might be due to some error in the endocrine system following from the imperfection of the testes themselves. When only one testis had failed to migrate the problem was difficult and he could offer no solution. In man there was little evidence of any hereditary predisposition; he had carefully inquired in all cases and only 2 per cent. of cases gave a history of a similar condition in grandfather, father, or brothers. As regards function, it was questionable whether an imperfectly descended testis was ever fully developed (it was incorrect to describe it as atrophied). In man there was a greater likelihood of spermatogenesis in the abdominal testis than in the testicle retained in the inguinal canal; instances of procreation by men with double abdominal testes were fairly common, but it was rare to find parentage permitted to men with double inguinal arrest. The internal secretion of the abdominal testis appeared to be preserved in some degree, although perhaps not fully.

A testis within the abdomen of man was liable to the same diseases as was the fully migrated organ. Gonorrhœal epididymitis might occur and be easily mistaken for appendicitis. Cysts of the testis proper were rare; simple cysts of the epididymis had been described. It was doubtful whether testicular tumours, almost always highly malignant, such as malignant teratoma, carcinoma, sarcoma, and chorion-epithelioma, were any commoner in the retained testis. As regards treatment, the only condition which called for interference was inflammation of an abdominal testis, when the organ should be promptly removed. To replace an abdominal testicle in the scrotum was impossible, and its removal involved a loss of the internal secretion.

Sir **John Bland-Sutton** referred to the attention that had been devoted to this subject both in man and animals since the days of Hunter, who first traced the gubernaculum by dissection and suggested that malposition of the testis was due to imperfection of the gubernaculum. The frequency of unilateral retention of the testis disposed at once of the hormone theory. He suggested that cryptorchidism might be in some way associated with an imperfection of the curious readjustment of the peritoneum which occurred during later fœtal life. The dermoid tumours of the testis so common in the horse arose, as Verneuil had pointed out, not from true testicular substance but from the paradidymis. It was strange that they should be so common in the retained testis of the horse, while in man but 13 dermoids of the testis were recorded in the literature and only one of these was in a retained testis. He suggested that the tissue lying between the testis proper and the epididymis of the fœtal horse might form a fruitful field for further investigation.

In answer to questions, Prof. **Hobday** re-stated his belief in the hereditary nature of cryptorchidism in the horse. In one particular district where a "rigg" had been used at stud, he was called upon to operate on 10 or 12 horses every year for cryptorchidism.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Exhibition of Cases and Specimens.

The annual meeting of this section was held on Oct. 26th, with Mr. **Anglin Whitelocke**, the President, in the chair.

Mr. P. **Lockhart-Mummery** showed a case of hemi-hypertrophy traced for 18½ years. The patient was first exhibited before the section in January, 1906.[1] It was shown in collaboration with the late George

---

[1] Proceedings, 1906, vi., 153.

Carpenter. The child was then 2½ years old, and the left side of his body and head was growing faster than the right side. He was originally brought to hospital because he was walking lame. There was nothing else wrong with the child; the mental condition was normal, and no abnormalities were detectable in the nervous system. The difference in length of the lower limbs was half an inch. The child was again exhibited at the Society in January, 1908. He was now very lame, and there was 3½ in. difference between the length of the legs. X ray photographs showed the epiphysis to be more advanced on the left side than on the right side. The child appeared to be two years older on the left side than on the right side, and the left side of the tongue, the left eye and ear were all larger than the right. The patient was now shown at the age of 21. There was now only half an inch of difference between the two sides, and it was obvious that the small side was now catching up with the big side. Except on close observation no difference between the two sides of the face or tongue could be detected. As far as the speaker was aware this was the only case that had been traced to adult life.

Dr. F. J. POYNTON showed two cases—one of unilateral and one of bilateral congenital dilatation of the ureters. In the former the diagnosis was confirmed by a post-mortem examination. The diagnosis was made in life by the aid of a cystoscopic examination and by the X rays after injecting 20 per cent. sodium bromide into the bladder and ureters. In both cases there was a gross infection of the urinary tract. The question of the causation of the dilatation was discussed and the majority of those present seemed to favour the presence of a spasm of the urethra.—Dr. DINGWALL FORDYCE suggested the possibility of this spasm being analogous to that of pyloric stenosis. He thought it doubly interesting because the elder of the two children and the one in which the condition was bilateral was a girl.—Mr. MAX PAGE suggested that if this condition was analogous to pyloric stenosis, it might be treated upon the same lines by section of the sphincter.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

A MEETING of this Society was held in Manchester on Oct. 19th, the President, Prof. BLAIR BELL, being in the chair.

Dr. D. DOUGAL (Manchester) read a paper on the

Operative Treatment of Incontinence of Urine in Nulliparæ.

He said that the degree of control has been expressed by Taylor and Watt as (1) normal; (2) fair, which is normal except on special occasions, as, for example, over-distension of the bladder, temporary vesical irritability, or times of mental or physical fatigue; (3) poor, which allows the urine to escape on any special abdominal strain, such as may be caused, for example, by coughing or active exercise, such patients being wet most of the time; (4) lost, when urine continually dribbles from the patient and very little is retained in the bladder. Taking the "poor" and "lost" groups only, the figures showed that about 8 per cent. nulliparous women suffer from disagreeable amount of urinary incontinence (Taylor and Watt). In this paper Dr. Dougal proposed to deal only with those cases of active incontinence of urine which are due to weakness of the vesical sphincter. He said that the sphincter apparatus of the bladder consisted of three parts: (i.) Intrinsic sphincter, which is merely a specialised portion of the middle stratum of bladder musculature. Its presence is even denied by some authorities. (ii.) Extrinsic or urethral sphincter composed of fibres of compressor urethræ forms a complete ring round the upper part of the urethra. All authorities are agreed that this is the most important factor in sphincter apparatus. (iii.) The supporting fibromuscular tissues lying between base of bladder and the anterior vaginal wall. It is made up of paravesical vascular sheaths and their connexions, and is strongly developed towards each side, where it is closely related in front to the anterior layers of the levator ani and behind to the parametric tissue. He considered that the sphincters are the most important factors and, in support of this contention, he cited the fact that incontinence of urine is not commonly met with in cases of prolapse, even when the anterior vaginal wall, and presumably the supporting structures of the bladder, are much weakened and displaced. He described the more important operations for the cure of this condition illustrated by lantern slides. The operation he performed on his successful cases was as follows:—

The perineum was first incised to allow of easier access to the parts. A triangular area of the anterior vaginal wall was then removed, exposing the urethra and bladder. A mushroom catheter was then passed into the bladder, and using this as a guide two mattress sutures of catgut were inserted into the tissues on each side of the bladder neck (after Kelly). Deep sutures were then inserted through the para-urethral tissues to narrow the canal throughout its length, and the anterior colporrhaphy then completed in two layers. Finally the perineal incision was sutured.

He added notes on two cases.

1. This patient was an unmarried woman, aged 26 years. Menstrual history normal, thin, poorly nourished, very little energy, and very depressed and miserable. Had suffered from urinary incontinence practically since birth, worse at night. All sorts of medical treatment tried. The external genitals were normal and of virginal type. The vaginal orifice admitted one finger with difficulty, but the upper part of the anterior vaginal wall appeared somewhat lax, although there was no actual prolapse. The uterus was normal in size and acutely anteflexed. After the operation, as above, she needed catheterisation for a week. Her bed was wet once before discharge from hospital. She had been well ever since—for two and a half years—and was now cheerful and healthy.

2. This patient was also unmarried, aged 21 years. Menstrual history normal, rather thin and miserable, and not very bright mentally. She was perfectly normal till an acute illness ten years ago, but since then had been incontinent, chiefly at night, but also during the day. For the last six years had not had a holiday owing to bed-wetting. External genitals normal, vaginal orifice virginal, and again a considerable laxity of upper part of the anterior vaginal wall was found. The uterus was normal in size and acutely anteflexed. It was over six months now since the operation and she had wetted her bed twice, but she had now been away for a holiday and was much better in every way.

The great majority of these cases of incontinence could be cured or, at any rate, much relieved by operative treatment. There was no doubt that many young single women are allowed to go on suffering from this distressing ailment because no obvious lesion could be made out, and the disability was attributed to neurosis. There is a neurotic element, no doubt, in some cases, but the real underlying cause would be found in a weakness of the sphincter mechanism, which could often be dealt with successfully by surgical methods.

Discussion.

In the discussion which followed, Dr. MILES PHILLIPS said he thought that incontinence of urine was a common feature of partial vaginal prolapse in multiparæ.—The PRESIDENT expressed surprise at the high figure (8 per cent.) of incontinence in nulliparæ. He did not believe that incontinence was due to neurosis. There was not a single structure in the apparatus which could be said to constitute a true sphincter.—Prof. W. E. FOTHERGILL said he had done Pawlik's operation a few times with success. He questioned that incontinence of urine was common in cases of vaginal prolapse in multiparæ. He thought that the operative measures taken were a suggestive treatment.—Dr. H. LEITH MURRAY said that the fact that the incontinence was worse at night pointed to a neurotic element rather than to the dislocation theory.

Specimens were exhibited by Dr. J. H. WILLETT, Dr. LEITH MURRAY, and Dr. J. E. GEMMELL.

Reviews and Notices of Books.

The Blood-Sugar in Man.

Investigations on the Blood-Sugar in Man. Conditions of Oscillation, Rise, and Distribution. By Karen Marie Hansen. Copenhagen: Nielsen and Lydiche (Axel Simmelkiaer). Obtainable from H. K. Lewis and Co., Ltd., London. 1923. Pp. 224. 10*s*.

This monograph was written for the degree of Doctor of Medicine in the University of Copenhagen, and gives the results of an enormous amount of research work which was done in the clinic of Prof. Kund Faber. Whereas most workers are content to estimate the blood-sugar every 15 or 30 minutes after a dose of sugar, Dr. Hansen has estimated it as often as she could find time to collect a sample of blood—i.e., every two to three minutes—and the results are plotted in the form of a curve. An elaborate series of controls was made, and the author believes that the Hagedorn and Jensen method for estimating the blood-sugar is accurate to 0·005 g. per cent.

It was found that the blood-sugar of a fasting healthy person was not constant but might vary from 0·085 per cent to 0·105 per cent. in a series of irregular oscillations. These oscillations were not present when the blood-sugar was increasing after a dose of sugar, but appeared if a plateau was formed. They disappeared when the blood-sugar was falling, to reappear as soon as it had fallen to somewhere near its original level. These results were obtained as a control for similar but more pronounced oscillations which occurred among the numerous diabetic patients who were examined. The curve showing the gradual fall of the blood-sugar of a diabetic patient during a fast is very striking. Elaborate curves were obtained from healthy persons showing the effect of increasing doses of sugar. A series of diabetic patients was also examined after doses of sugar before and after treatment. An attempt was made to see whether the sugar tolerance of the patient had changed as the outcome of treatment. The results seem to show that although the fasting value of the blood-sugar might fall to normal under treatment, there was but little evidence of a recovery of tolerance. It must be pointed out, however, that the amount of carbohydrate in the patient's diet would hardly give the patient much chance of a recovery of sugar tolerance. The partition of sugar between the plasma and corpuscles was also investigated. In health it was found that the sugar was almost equally shared between them. In patients with severe diabetes, however, the plasma contained more sugar than the corpuscles. Under treatment there was an approach to the normal condition.

The monograph is written in fair English. For all workers on sugar tolerance it will be of great assistance, both for the references to other work and for the numerous experiments described.

Surgery of the Spine and Extremities.

By R. Tunstall Taylor, M.D., Professor of Orthopædic Surgery, University of Maryland, and College of Physicians and Surgeons. London: Stanley Phillips; Philadelphia: P. Blakiston, Son and Co. 1923. With 604 illustrations. Pp. 550 + x. $7.50.

Dr. Tunstall Taylor is well-known as an orthopædic surgeon, and we welcome this expression of his matured experience in the treatment of deformity. Although the term is not included in the title, the opening chapter begins with an attempt, in which the author is not more successful than his predecessors, to define orthopædic surgery. In this connexion we would remark that the genitive of *παῖς* is not *παιδὶς*, and that we find no such word as "fenestrum" in our Latin dictionary. But we note that Dr. Taylor has abandoned the usual American "orthopedic" for the more correct spelling. The historical notes are of some interest and well illustrated, but scant justice is done in them to the part taken by English surgeons in the development of orthopædic surgery. It is, moreover, strange that the only name mentioned in connexion with the Balkan Frame is that of an American who did not serve in the Balkans and had consequently nothing to do with the original invention, however successfully he may have applied it in France. The descriptions of apparatus and of the technique of its preparation and application are likely to prove useful, as also is the chapter on surgical mensuration, although we think that elaborate instruments are out of place where the data—i.e., the bony points and axes—are so ill-defined as they must necessarily be in the living body. In the chapter on tuberculous diseases of the spine, treatment by means of the Taylor brace and other methods are adequately described, but heliotherapy and open-air treatment are only alluded to. Scoliosis is adequately dealt with. The chapters on diseases of the joints of the limbs, and of congenital dislocation of the hip present a good account of the usual American practice in the treatment of these conditions, but call for no particular notice. Infantile paralysis is discussed less fully than one expects in a text-book coming from America, where epidemics of that malady have been so extensive. The chapter on the deformities of the foot is disappointing. For instance, in the section concerning talipes calcaneus no clear distinction is drawn between the relative prognostic importance of the congenital and paralytic cases of this deformity, and operations for the relief of the latter are most inadequately described. The chapter on reconstructive surgery of the hand and the details given of the technique of tenoplasty are likely to be very useful. The illustrations are many and good and the work may be recommended as a text-book of the subjects included under its title.

Treatment by Artificial Pneumothorax.

La pratique du pneumothorax thérapeutique. Second edition. By F. Dumarest and P. Brette. Paris: Masson et Cie. 1923. Pp. 356.

Since the first edition of this work was published, certain important advances have been made in our knowledge of treatment by artificial pneumothorax, and the graduation of the intrapleural pressure to suit the needs of the individual case has of late received much more attention than it did. The general tendency is to use lower pressures. Another recent advance, to which these two authors have contributed not a little, is the distinction between the various kinds of pleural effusion, from the simple traumatic effusion at the one extreme, to the virulent tuberculous effusion at the other. With an experience of 15 years and between 200 and 300 cases, the authors are in a position to speak with authority, and it is interesting to note that in their selection of cases for this treatment they have learnt to be guided rather by the clinical course of a case than by the structural changes indicated by a physical examination. Such an examination may show but slight changes in the lungs. Yet the disease may be of a rapidly progressive character, and the patient acutely in need of that immobilisation which only lung collapse treatment can effect.

The authors refer in their introduction to the fact that in France, at any rate, opposition to this treatment has practically died down, its many permanent successes having given the lie to the objection that it was only palliative, scoring successes of a merely temporary character. The authors have obtained favourable results in 52 per cent., and after an observation period of more than ten years they were still able to claim favourable results in 23 per cent. They refer among other matters to the treatment, during and after pregnancy, of tuberculous women by a pneumothorax. While in Germany it is usual to induce abortion early in pregnancy when a woman is suffering from active tuberculosis, this procedure has found little favour in France where the more conservative measure of inducing a pneumothorax has frequently enabled the patient to go to term, giving birth to a healthy infant without suffering from an exacerbation of the disease. In their account of the technique of the operation, the authors reproduce numerous illustrations of the various pumps and needles in use. There seem to be almost as many different pumps and needles as there are physicians practising this treatment, but a close scrutiny of all this apparatus arouses the suspicion that the differences begin and end with the physicians' names. There is, however, a remarkably ingenious portable apparatus, associated with the name of A. Jousset, which looks as if the whole bag of tricks could be accommodated in a poacher's pocket. With regard to the old controversy as to sudden deaths being caused by gas embolism or pleural reflex, the authors are inclined to hold each of these causes responsible for a certain proportion of the tragedies of this treatment. But when they suggest that the accidents traced to pleural reflex are comparable with those of serotherapy, they fail to make their reasoning quite plain.

This book does not profess to be an exhaustive treatise on the subject, but embodying as it does the personal experiences of two physicians with a long and intimate knowledge of this treatment and of the recent literature, the book is of considerable value.

Psychotherapy.

Revised edition. By JAMES J. WALSH, M.D., Ph.D., Sc.D., Extension Professor, Fordham University. London and New York: D. Appleton and Co. 1923. Pp. 846. 30*s*.

Dr. Walsh opens with an interesting study of the history of mental healing and then passes to consider the body and mind in a manner which can be illustrated by the statement that "The will fails to reach the proper insulating plug of a neuroglia cell, which, if acted upon, would put a cell or group of cells in communication with others" (p. 128). Over 300 pages are given to the study of common ailments met with in general practice; here are considered digestive disturbances, cardiac disabilities both organic and functional, respiratory diseases (concerning which the neglected relation between asthma and pathological fears is demonstrated), the "rheumatisms," genito-urinary diseases, skin diseases, diabetes and exophthalmic goitre, and organic nervous disease. The general indications for psychotherapy are useful, but the author's ideas of therapy are disappointing. Suggestion, whether by newspapers, medical men, or relatives, is the beginning and end of his psychopathology; and his therapeutic directions are tedious in their repetitions. The need for reassurance, absence of worry, occupation of mind, neutralisation of unfavourable suggestions, self discipline and control of the mental attitude and of the nervous system are insisted on, and abundant platitudes leave the reader where he began.

It is in regard to purely mental troubles that we realise the emptiness of a therapy that takes no count of unconscious processes. Dr. Walsh quotes the case of an author suffering from claustrophobia: "He was returning from a vacation and was in the best of health and spirits, yet suddenly the feeling of inordinate dread that he was shut in came over him and he could scarcely control himself or keep from plunging out of the window in order to get into the open. . . . Unable to control himself any longer he got up and told me hoarsely that he was going to jump out of the train. . . . Happily the railway station was soon reached, when he rushed from the train and into the fields" (p. 617). The practitioner faced with the problem of treating such patients will gain little help from the advice that "Gradually, quietly, persistently, they must resist the dreads that come over them, must deliberately, without excitement, do the opposite to that suggested by their apprehension, until habits are formed that enable them to accomplish without discomfort what was before a source of serious ill-feeling" (p. 620). Keep your head above water and you will never drown. The handling of the defective child has no difficulties for our author. "The defective child must be made to realise that certain actions will surely be followed by painful punishment" (p. 742), and he demonstrates that the "subrational" needs more punishment than the rational. He seems to regret the decay of the practice of whipping hysterical patients (p. 805), and notes that the French military authorities revived this therapeutic measure in *torpillage* or the application of strong faradic currents. He concludes that "*Torpillage* . . . . is by its success the open sesame to proper understanding of the nature and therapeutics of hysteria." Dr. Walsh's book is not to be regarded as an exposition of modern American methods of psychotherapy.

Moral Problems in Hospital Practice.

By the Rev. PATRICK A. FINNEY, C.M., University of Dallas. London and St. Louis, Mo.: B. Herder Book Co. 1922. Pp. 208. 6*s*.

THIS is a work upon pastoral medicine written from a definitely Roman Catholic standpoint; that is to say, that the rules laid down for the conduct of medical men under certain conditions are those prescribed by Roman Catholic theologians. It is no part of our duty to comment upon such rules, and we refrain from so doing all the more in that we see that upon one matter at least—namely, the production of abortion in an incarcerated pregnant uterus—the Rev. Patrick Finney (p. 63) is in direct conflict with Dr. Capellmann, who lays it down in his work, "Medicina Pastoralis," p. 15,[1] that such procedure is indirect abortion and therefore lawful. But for those who feel bound by the regulations laid down by the Roman Catholic Church in such matters as abortion, sterilisation, craniotomy, ectopic gestation and the like, the book will be found valuable. It is clearly written under the form of questions and answers, which are given baldly in Part I., while in Part II. the questions and answers are repeated with a discussion and statement of the principles and reasons upon which the answers are based. Further, the book has a satisfactory index, glossary, and bibliography.

Manual and Atlas of Otology.

Lehrbuch und Atlas der Ohrenheilkunde. Fourth edition. By Prof. Dr. GUSTAV BRÜHL. Lehmann's Medical Hand-Atlases, Vol. XXIV. Munich: J. F. Lehmann. 1923. Pp. 487. 14*s*.

THIS bulky volume is printed in small type and, suffering somewhat from over-condensation, makes heavy reading. Condensation was, however, necessary if the book was to be kept within a reasonable compass, and perusal is well worth the effort it demands, for the book contains a very thorough and complete description of modern otological knowledge. The work begins with a full account of the anatomy of the ear, macroscopical and microscopical, and is provided with abundant illustrations; the physiology is treated comparatively shortly, Helmholtz's theory of audition is accepted in its entirety, and neither Gray's modification nor Wrightson's alternative theory is mentioned. The next section deals with methods of examination, and here the testing of the labyrinthine functions are well described. A chapter on general symptomatology and therapeutics is followed by a systematic discussion of the pathology and treatment of diseases of the ear under the headings of outer and middle and internal ears. Malformations, injuries, and tumours are described subsequently in separate chapters, instead of among the diseases of the several parts of the ear; this arrangement leads to some confusion and overlapping, and it is not easy to see why it was adopted. There are also chapters on deaf-mutism and neuroses, and finally discussions of the social aspects of ear disease, in its bearings on military service, life insurance, and workmen's compensation. A very complete table of contents compensates partially for an inadequate index. The illustrations are excellent, more particularly those in colour, which are a prominent feature of the book.

---

[1] C. Capellmann: Medicina Pastoralis. Aquisgrani, MDCCCXC.

THE DIAGNOSIS AND TREATMENT OF HEART DISEASE.

Fifth edition. By E. M. BROCKBANK, M.D. Manch., F.R.C.P., Hon. Physician, Royal Infirmary, Manchester; Lecturer in Clinical Medicine, University of Manchester. London: H. K. Lewis and Co., Ltd. 1923. Pp. 232. 6*s.* 6*d.*

IN this, the fifth, edition of Dr. Brockbank's well-known handbook the chapters on clinical examination have been rearranged and extended. Several chapters have been added on the treatment of the common forms of illness in which the heart is affected. A chapter containing hints on the way to examine proposers for life insurance and on the interpretation of certain abnormalities in the circulatory system will be found especially useful in view of the author's long experience. We note that in Dr. Brockbank's opinion a stethoscope made of light wood, such as sycamore wood, gives the most delicate results in ausculation, but he admits that the binaural variety is often more convenient. The section of the volume dealing with heart sounds and murmurs is especially clear. For the rest, the popularity of previous editions of this little book among students and practitioners is likely to be maintained.

WHAT TO EAT IN HEALTH AND DISEASE.

By BENJAMIN HARROW, Ph.D., Associate in Physiological Chemistry, College of Physicians and Surgeons, Columbia University. London: George Routledge and Sons. 1923. Pp. 203. 8*s.* 6*d.*

FEW branches of physiological knowledge have such an attraction for the layman as the subject of diet. Until quite recently, however, few if any reliable books have come forward to supply this demand for knowledge, and the subject of diet became a happy hunting ground for all varieties of cranks and quacks. It is different to-day, for now there is an almost bewildering profusion of popular books in which the layman can put complete confidence. The volume before us fulfils the necessary requirements of being simply written, accurate, and interesting. The placing of the chapter on the physiology of digestion at the end, instead of at the beginning of the book is an arrangement the desirability of which might reasonably be questioned, but the author draws attention to this by suggesting that some readers may prefer to read the last chapter first.

The book is intended as a guide for those who wish to know what to eat and why to eat it. But it is not merely this—it is also a reasonably complete account of the subject from the standpoint of the most recent work, including the experience gained by the study of war and post-war food conditions in Europe. Thus, the Pirquet system in which the nutritional value of the diet is measured in the new unit, the "nem" (1 c.cm. of milk = 1 nem), is discussed. The author has apparently a very decided leaning towards a reduction of the amount of meat in the diet, if not to frank vegetarianism.

DENTAL SURGERY AND PATHOLOGY.

Fifth edition. By J. F. COLYER, K.B.E., F.R.C.S., L.D.S., Consulting Dental Surgeon to Charing Cross Hospital. London: Longmans, Green and Co. 1923. Pp. 931. 32*s.*

THIS well-known text-book has held an almost unchallenged position in dental literature for many years. Numerous generations of students have been nurtured on it and to an unusual degree the views of its author are reflected in the teaching and practice of dentistry in this country. There are many excellent reasons for its vogue. It is clearly and concisely written, and the illustrations are ample and instructive. There is throughout a sound insistence on pathology. It embodies a great deal of original work. The teaching is dogmatic, yet there is a recognition that dogma is not always adequate, and that there may be another side to the matter under discussion. Perhaps the greatest merit of the book is the constant insistence that dentistry is a branch of general medicine and cannot be considered as a matter of teeth alone.

The general arrangement of the book follows that of previous editions. There are, however, certain changes. The description of operative procedure has been considerably curtailed. This is an undoubted improvement. Dentistry has grown so rapidly that one book is no longer adequate to cover fully the whole of dental surgery. The section on orthodontic technique is hardly a sufficient account of modern orthodontic methods. The chapters on malocclusion and their ætiology represent much original work and thought, though in many respects they run counter to current teaching.

The chapter on dental caries is a little disappointing. It is so good that we feel it ought to be still better. Reading it the student would gain the view that the ætiology and pathology of dental caries form practically a closed book. Perhaps the author thinks thus, but there are many observers who consider that there are yet chapters waiting to be written, and that we have much to learn about the pathology of dental caries. In the chapter on tumours of the jaw, a distinction is drawn between the myeloid epulis and the myeloma. According to M. J. Stewart,[1] there is no real difference between the two tumours which are equally examples of the myeloid sarcoma. There is a useful chapter on Local Anæsthesia by F. J. Steadman, and an instructive account of radiographic changes in chronic infection of the jaws by Stanley Colyer.

The popularity of this well-known book will be assured by the new edition.

THE ACTION OF ALCOHOL IN MAN.

By E. H. STARLING. With Essays by R. HUTCHISON, Sir FREDERICK W. MOTT, and RAYMOND PEARL. London: Longmans, Green and Co. 1923. Pp. 291. 12*s.* 6*d.*

Prof. Starling believes that if the abolition of all alcoholic beverages were enforced in this country against the wishes and convictions of a large proportion of the members of the community it would be little short of a calamity. Not only would it "not result in the long run in the improvement of national health and efficiency," but it would also "diminish that respect for the law, and that identification of self with the law which are essential for the stability and welfare of a democracy." Alcohol, an invention which he regards as probably synchronous with the birth of civilisation, has, in Prof. Starling's opinion, its chief value in "promoting repose and in affording a respite from the continual effort at adaptation to environment, and from the perpetual necessity of reconciling our personal advantage with the requirements of the society in which we live."

The book consists of 13 chapters by himself, in which he deals, in language addressed largely to the layman, with the fate of alcohol in the body, its action as a food, and its influence upon fatigue, digestion, circulation, respiration, and regulation of body temperature; with its action upon human behaviour and its influence on the community; with the effects of its "immoderate use," and with his conclusions drawn from the numerous experiments quoted. He is unable to find any evidence for the view so often expressed that the moderate use of alcoholic beverages is, in itself, harmful, and leads in the long run to the deterioration of health and of morality, but admits that its excessive use is the cause of a large amount of disease, crime, misery, and inefficiency. The worker will find that 12 c.cm. of alcohol contained in a glass of beer or a wine-glass of claret taken with lunch "will not interfere with the carrying out of his afternoon's work." The 35 c.cm. of absolute alcohol contained in half a bottle of light wine (claret or hock), in a pint and a half of ale, in 3 oz. of whisky (30 under proof), or in a quarter of a bottle of port, will undergo complete oxidation in the body within three and a half to five hours, so that if this amount is taken with the evening meal the alcohol will have disappeared from the blood and body tissues many hours before it is necessary to get up in the morning and begin the day's work. These quantities, consumed daily, will, in Prof. Starling's opinion, not interfere throughout adult life with bodily health and efficiency, whilst sufficing to produce the benefits and the increased pleasure in life which are the objects of the enjoyment of alcoholic beverages.

---

[1] THE LANCET, Nov. 25th, 1922.

Dr. Robert Hutchison deals with alcohol as a medicine, in its aspects of a food in disease, an aid to digestion (e.g., in atonic dyspepsia), a tonic for "run-down" patients, a drug in disorders of the circulation and heart, and a sedative and hypnotic. Sir Frederick Mott treats of alcohol and its relations to problems in mental disorders, and characterises as misleading the statement, made by an extreme section of the temperance party, that 20 per cent. of admissions to asylums are directly or indirectly due to alcohol. Prof. Raymond Pearl's contribution relates to alcohol and mortality. He draws from a profusion of statistics the following conclusion:—The weight of evidence indicates that the consumption of alcoholic beverages "up to an amount and frequency which in common parlance is called moderate (the precise measure of this amount and frequency probably varying to some extent with each individual) does not sensibly shorten the mean duration of life or increase the rate of mortality, as compared with that enjoyed by total abstainers from alcohol."

Nowhere in the book is there any attempt to balance the cheerfulness and sociability engendered by the week's beer against the desirability of, say, the repair of a child's boots.

SCIENCE AND CIVILISATION.

Essays arranged and edited by F. S. MARVIN. The Unity Series, Vol. VI. Oxford University Press. 1923. Pp. 350. 12*s.* 6*d.*

"SUMMER schools" are of comparatively recent growth. Mr. Marvin started the first of these "Unity History Schools" in 1915, in the congenial atmosphere of the Friends' Settlement at Woodbrooke, when papers and discussions centred round the unity of western civilisation. The seventh, dealing with art and civilisation, was held this year in Vienna. The present volume is a record of the more permanent parts of the sixth conference, and contains a dozen essays grouped round the central theme. As might be expected from anything arranged by the author of "The Living Past," the note through the whole series is the continuousness of human experience and progress. The past is not an archæological curiosity but an integral part of the present, because the present is its derivative. And through this volume, as through its predecessors, runs another character which has commended them to so many diverse readers—the note of cheerful hopefulness for the future. If, for example, Greek mathematics have done so much for us in the past 2000 years, may not their products reasonably be expected to do as much again for us in the future? The argument throughout is that the past is alive, and may be presumed to be going to propagate itself in the future. It is impossible to deal with the essays individually. Those on "Ancient Medicine," by Dr. Charles Singer, and on "Science and Health," by Dr. F. G. Crookshank, are of more immediate professional interest, and it is a sign of the times that the grandson of Thomas Henry Huxley contributes one on "Science and Religion." Dr. Crookshank's discourse is particularly worth attention, and medical men would do well to respond to his invitation to think seriously as to what they really mean by a "disease." But the volume should be read as a whole. It will prove a most useful purge to those who see in "science and civilisation" nothing but the progress of our materialistic control over nature.

JOURNALS.

JOURNAL OF THE ROYAL NAVAL MEDICAL SERVICE. In the last issue Surg.-Commander J. H. Fergusson states that sulfarsenol, introduced by Surg.-Commander Laurence Kilroy[1] to the Mediterranean Station, has been there under trial for two years, and is strongly approved because it can be given, with ease and safety and painlessly, by subcutaneous injection, therefore anywhere and immediately, so that treatment can be commenced the moment the sore is seen, before the infection is generalised, and the Wassermann becomes positive. Besides, it produces results at least as good as any other drug. Hundreds of cases have been treated with it without complications (only one case of jaundice and one of dermatitis are quoted). It causes so little trouble that it can be given to all cases of chancroid, and thus even the unsuspected cases of syphilis—there are some—are aborted at once. And if doubtful cases can be cured thus easily and without fail, why wait?—Surg.-Commander G. B. Scott, the genito-urinary specialist of the same fleet, recommends that a chancroid with 12 days' incubation be given sulfarsenol, and 4 (not 2) g., and two full courses, not one, for the man who has had a positive Wassermann. He discourages the use of mercury: "Why fiddle about with bad tools when better are available?"—Surg.-Commander H. E. R. Stephens reports a case of fracture of the erected penis. The patient during intercourse heard and felt the penis snap. Erection was at once lost, and the penis began to swell up. When he complained it was found there was a rounded swelling in the left corpus cavernosum, the whole of the penis and scrotum were black, the distal part of the penis was turgid and stiff, the proximal supple; only the glans was not swollen and still pink. After 12 days the general effusion was completely absorbed, but the lump persisted, and there was loss of function of the organ. An incision was made over the swelling and the clot was turned out; one artery required ligature, and the tunica albuginea was sutured. Recovery was rapid and full functional activity was regained.—Surg.-Commander W. H. Edgar tells us that he has had considerable experience of the trying complaint "tennis elbow," which he ascribes to a localised myositis of the extensors of the forearm and wrist, at their origin from the external condyle, and from the thin bony ridge which runs upward therefrom; on the myositis a periostitis supervenes. The trouble is due to the prolonged strain of the extensors of the wrist in the act of grasping the racquet. It also occurs in men who do not play tennis but have to hold small-handled tools, as in cutting off rivets with a small hand-hammer, or, the same muscular action, in wood-sawing. Other games than tennis make no such prolonged call on the grip of the right hand. When the patient complains it will be found that the pain is at once located in the external condyle if he be asked to clench his hand. To avoid this condition, play with a light racquet, and one with a thin handle, massage the extensors after each day's play, and avoid "rubber grips." In treatment, diathermy is very beneficial, also the galvanic current, with or without ionisation.—Dental fitness being very important, teeth are not to be extracted if they can be preserved, and dental officers are to give monthly lectures on oral hygiene, to be illustrated by lantern slides. These lectures to be optional to men generally, except to new entries, who will be required to attend.—A gold medal is now given annually to that member of the sick berth staff who has most distinguished himself by the exhibition of zeal and efficiency in the discharge of his duties during the preceding year. This year it was won by Sick Berth Petty Officer J. T. Forest.

THE WORK OF THE TUBERCULIN DISPENSARY LEAGUE.

We publish below the report to the Tuberculin Committee of the Medical Research Council on the work of the Tuberculin Dispensary League, Chelsea, with some introductory remarks from the Council, whose sanction, as well as that of the Ministry of Health, has been obtained for the publication.

Introductory Remarks from the Medical Research Council.

In July, 1919, members of the committee of the Tuberculin Dispensary League, Chelsea, addressed a letter to the Right Hon. Christopher Addison, M.P., M.D., then Minister of Health, requesting that he would cause an inquiry to be made into the work done at the Tuberculin Dispensary, Chelsea, with a view to increasing the number of tuberculin dispensaries and to making known the use of tuberculin as practised by Dr. Camac Wilkinson. It was urged by the committee that the economy and efficiency of the methods at this dispensary called for their adoption generally, and that the number of cases cured at Chelsea warranted the demand of the committee for an inquiry. This request was referred by the Minister of Health to the Medical Research Council, on whose behalf a committee was already engaged in research work upon tuberculin and in the study of its uses for diagnosis or treatment.

The Medical Research Council thereupon invited the committee of the League to state the nature of the evidence which the committee had at their disposal for judging the results of the methods of tuberculin treatment upon which they had addressed Dr. Addison. At various subsequent dates the committee of the League submitted (*a*) testimonials to the value of Dr. Camac Wilkinson's treatment from a number of patients and their friends or medical attendants; (*b*) reports on seven cases by the dispensary nurse; and (*c*) a short summary of the results of treatment of 71 cases in 1910–1912. Of these 71 cases 13 had been lost sight of, and of the remaining 58 cases 24 per cent. were dead, 26 per cent. were unimproved, and 50 per cent., of whom many had had other forms of treatment in sanatoria or elsewhere, were said to be improved.

The Medical Research Council in March, 1920, wrote to say that in their opinion the evidence submitted did not appear to justify the demand of the dispensary committee for a special inquiry into the work done there by Dr. Camac Wilkinson. They expressed the opinion that only the careful and unbiased collection of accurate records can serve to establish the merits of a given treatment, and that no public or private advocacy of a course of treatment is justified unless it be based on that foundation. Mr. Randall Davies, treasurer of the League, thereupon explained that the data submitted to the Council were only "samples and summaries somewhat hurriedly collected," and said that full and accurate records had been kept of every case treated. He expressed his personal regret for the misunderstanding and for the time spent upon the data now withdrawn. The Council replied that they were still willing to arrange for an unbiased study of the methods and results shown in the system of records now mentioned, if these were substituted for the imperfect records previously submitted.

After the lapse of three months the Council were informed (August, 1920) that the records were ready for examination. They were then able to invite the Tuberculin Committee of the Council to undertake the inquiry. The committee delegated the details of the investigation to three of its members—namely, Dr. G. T. Western, physician-in-charge of the Inoculation Department of the London Hospital; Dr. L. S. T. Burrell, physician to the Brompton Hospital for Consumption and Diseases of the Chest; and Dr. A. S. MacNalty, a medical officer of the Ministry of Health. From December, 1920, these investigators devoted much time to the inquiry and the drafting of a report. Their work was entirely unremunerated and was undertaken for the Tuberculin Committee solely in the interests of scientific truth. It was understood from the outset that Dr. Camac Wilkinson himself desired to be dissociated personally from the inquiry. To avoid any further misunderstandings the report was submitted to the treasurer of the League for discussion with Dr. Wilkinson before its final adoption by the Council and transmission to the Ministry of Health. As a result, some modifications were made by agreement in details of the report. The report was adopted by the Medical Research Council, who, on July 20th, 1921, transmitted copies to the League and to the Ministry of Health.

The chief conclusion drawn by the sub-committee and by the Council was "that the method of tuberculin administration advocated by the Tuberculin Dispensary League does not appear to have claims over other methods of treating tuberculosis, either with or without tuberculin, which would justify its general adoption." The report was not published, and in the absence of any expressed desire by the Tuberculin Dispensary League for its publication it was regarded as a confidential document. Neither the committee of the League nor Dr. Camac Wilkinson had up to that time expressed any opinion unfavourable to the capacity or experience of those who undertook the inquiry or to the painstaking fairness with which it was conducted. Dr. Wilkinson, however, has recently published a brochure entitled "The Tuberculin Dispensary for the Poor,"[1] in which he complains of the perfunctory character of the inquiry as conducted by the Medical Research Council. Mr. Randall Davies in a preface to the pamphlet gives an incomplete selection from his correspondence with the Council.

It may be noted here that it was not until after the report had been completed that the investigators were informed that they could have had the opportunity of examining all the available living patients included in the medical records submitted to them. In the course of the inquiry they were told that Dr. Wilkinson, as a concession, would permit the members of the sub-committee to visit the tuberculin dispensary and to see the actual work in progress, but that he did not desire to enter into any discussion with them in regard to the objects of their inquiry. They availed themselves of this permission and saw a series of cases which Dr. Cooke, an assistant medical officer of the dispensary, had assembled for their inspection. They naturally, however, rigidly observed the conditions upon which they were allowed this privileged visit to the dispensary.

In view of the publication of Dr. Wilkinson's pamphlet, the Council have now consented to the publication of their report in The Lancet. They publish it not because they or the members of the Tuberculin Committee are willing to enter into further discussion with the League or Dr. Wilkinson on the subject-matter of the report, but only to allow correction of the erroneous impressions conveyed in the pamphlet.

Report to the Tuberculin Committee of the Medical Research Council on an Examination of the Data Submitted by the Tuberculin Dispensary League, Chelsea, in Relation to the Treatment of Tuberculosis by Tuberculin.

The following document has been received, in answer to our request and with the sanction to publish of the Ministry of Health, from the Medical Research Council:—

At a meeting of the Tuberculin Committee of the Medical Research Council held on Dec. 7th, 1920, three members of the subcommittee, Dr. G. T. Western, Dr. L. S. T. Burrell, and Dr. A. S. MacNalty were appointed to investigate the data submitted by the Tuberculin Dispensary League and to report thereon to the Committee. We entered upon the nvestigation on Dec. 21st, 1920, and now submit our report. At the outset we desire to express our thanks for the assistance afforded to us in our investigation by Dr. Camac Wilkinson, Dr. Cooke, and Mr. Randall Davies, hon. treasurer of the Tuberculin Dispensary League.

---

[1] London: Nisbet and Co., Ltd. 1923. Pp. 67. 1s.

1. *Method of Investigation.*

We have examined the case-records and temperature charts of 147 cases treated under the auspices of the Tuberculin Dispensary League; 40 cases were, however, eliminated from detailed consideration as they were records of patients who for one cause or another discontinued treatment at the dispensary and did not undergo full courses of treatment. We conferred with Dr. Cooke, assistant medical officer at the Tuberculin Dispensary, Chelsea, in regard to the method and duration of tuberculin administration and the notes made in the case-records, and on Monday, Feb. 7th, 1921, we visited the Tuberculin Dispensary at Chelsea and saw the method of treatment in progress. We have also read the works "Tuberculin in the Diagnosis and Treatment of Tuberculosis," by Dr. W. Camac Wilkinson, and "Studies in Pulmonary Tuberculosis," by Dr. F. G. Griffiths, both of which deal with the special method of tuberculin treatment now under consideration.

2. *Description of the Method.*

The tuberculous patient is treated with tuberculin as an out-patient. He attends at the Tuberculin Dispensary which is open twice a week. The patient is given a clinical thermometer and instructed how to take his own temperature at four-hourly intervals in a day of 16 hours. At his first attendance he is clinically examined. In doubtful cases or in cases in which no evidence of tuberculosis has been previously obtained the patient is given an injection of old tuberculin (0·001 c.cm. up to 0·01 c.cm.) for purposes of diagnosis. If the temperature transiently rises to 100°, 101°, or even 105°, he is considered a positive case of tuberculosis. If there is no reaction the patient is considered non-tuberculous. It should be emphasised, however, that all the cases submitted to our inquiry were stated to have had tubercle bacilli present in the sputum at one time or another during the period of treatment, although in a certain number of cases the tuberculin test had been applied for purpose of diagnosis before the result of the bacteriological test was known. It does not therefore come within the scope of our inquiry to express any opinion as to the accuracy of the tuberculin test in the diagnosis of cases of tuberculosis. If the patient's temperature initially exceeds 99·6° F., he is told to take his temperature regularly for a week in order to see if he is a suitable subject for treatment. Practically, however, the only contra-indications recognised appear to be the presence of acute or chronic renal disease.

The tuberculins employed in treatment have been P.T.O., P.T., O.T., and T.A.F., and in certain cases B.E. (Meister, Lucius, and Brüning) latterly, owing to difficulty in obtaining these tuberculins P.T.O. (Burroughs, Wellcome) and P.T. (Meister, Lucius, and Brüning) have been employed. The treatment begins with P.T.O., then proceeds to P.T., and finally old tuberculin is used. Dr. Camac Wilkinson describes the technique as follows: "If one begins with 0·001 c.cm. or 0·0001 c.cm. and proceeds to a final dose of 1 c.cm. to 2 c.cm. of O.T. the final dose is literally a quarter of a million to two million times as potent as the first dose. To reach this large dose one proceeds by gradual increases, avoiding, as far as possible, reactions much above 100°. To measure the small doses one requires a 1 c.cm. syringe, a pipette of fine calibre on which one can measure off 1/10th c.cm. and the ordinary diluting fluid (normal saline, containing ½ pint per cent. carbolic acid). After marking with ink the point of the pipette, which measures 1/10th c.cm., one passes the ink-mark through the flame to fix it. By my plan it is usually necessary only to make one dilution, that of P.T.O. in the strength of 1 in 10. This dilution of 1 in 10 is made by putting one part of P.T.O. in a sterilised watch glass and adding to it nine times the quantity of the diluting fluid (normal saline with ½ per cent. carbolic acid). Then, in order to measure 1/1000th c.cm. of P.T.O., one merely takes in the pipette a column of this diluted fluid equal to 1/10th part of the column, which represents 1/10th c.cm. If one wishes to measure 1/10,000th c.cm. (·0001 c.cm.) one must make a first dilution of 1 in 100 instead of 1 in 10" ("Tuberculin in the Diagnosis and Treatment of Tuberculosis," W. Camac Wilkinson, London, 1912, p. 429). The dose of tuberculin is given by a Koch's syringe graduated in 1/10th and 1/20th c.cm. and is usually injected into the upper arm on the outer side. Dr. Camac Wilkinson lays stress upon the fact that due aseptic precautions should be observed in giving the injection and informed us that no local septic complications had ever occurred in his experience. A square of sterilised court plaster is placed upon the site of injection. The technique as described above appears to us to be unsuitable for general adoption as it is somewhat crude and cumbersome.[2]

After the course has been completed, that is, when the dosage of tuberculin has reached 1 c.cm. or 2 c.cm., treatment is stopped and the patient is advised to attend the dispensary from time to time for re-examination. If the patient subsequently has a relapse as evinced by sputum and pyrexia he goes through another rapid course of tuberculin. Such a course might commence with 0·01 c.cm. O.T. up to 0·5 c.cm. O.T.; then proceeding to 0·015 c.cm. B.E. terminating with 0·5 or 0·6 c.cm. B.E. The aim is to produce "so big a general reaction that the patient cannot bear any more tuberculin" (statement of Dr. Cooke). The doses of tuberculin are given every third day or twice a week.

The course of tuberculin treatment usually occupies a period of six months to nine months; in some instances the course takes 9 to 12 months. The actual cost of tuberculin is about £2 2*s*. a course.

* If "a general reaction" occurs in the course of treatment, by which Dr. Camac Wilkinson means a rise of temperature up to 99·4° F., the same dose is repeated on the next occasion.

* If the rise of temperature, however, exceeds 99·4° F. a week is allowed to elapse and the last dose is repeated. As a rule, no "reaction" follows on the repetition of the dose. It is held that doses have to be given frequently and in increasing amounts in order to obviate anaphylaxis. In Dr. Cooke's experience Dr. Camac Wilkinson has not had more than four or five cases of anaphylaxis.

* Dr. Cooke mentioned that occasionally cases of extreme "hypersensitiveness" to tuberculin occurred in which a rise of temperature (a reaction) occurred after each repetition of the dose of tuberculin. In these cases the dose is reduced; small doses are given every day and then the course of treatment is continued.

It is not clear in what way such cases of "hypersensitiveness" to tuberculin differ from those of anaphylaxis.

3. *Cases Suitable for the Tuberculin Treatment.*

Practically every form of tuberculosis has been treated by Dr. Camac Wilkinson's method. He states that cases of lupus do not do well with tuberculin, and that mixed infections are not susceptible to treatment by tuberculin; rather their presence contra-indicates its use. In the practice of the dispensary, however, cases of pulmonary tuberculosis apparently in an advanced stage of the disease and with the high or intermittent type of pyrexia which Dr. Camac Wilkinson regards as characteristic of mixed infections have been treated with tuberculin, and in certain of these cases the condition appears to have been ameliorated. Dr. Wilkinson estimates that adopting the Turban-Gerhardt classification of cases of pulmonary tuberculosis treated by tuberculin on his method 80 per cent. of cases in Stage I. and Stages I.–II. are improved by the treatment, and 60 per cent. of cases in Stage II. derived benefit from it. This estimation apparently takes into consideration a number of cases classed as tuberculous on the results of the tuberculin diagnostic test. The above figures do not appear to be in advance of those which may be obtained by other methods of treatment either with or without tuberculin.

4. *Description of the Case-Records.*

The case-records submitted for our inspection consist of brief notes of the clinical examinations made on a case-sheet and temperature charts made from temperature records kept by the patients themselves; upon the charts the doses of tuberculin and the kind of tuberculin administered are noted by the medical officer of the dispensary. A record of the weight of the patient is also kept. It is stated in every case that tubercle bacilli have been found in the patient's sputum in the early stages of treatment by tuberculin. In a certain number of cases the report had not been received at the initiation of the treatment or no sputum was available at the time. In such cases the treatment was commenced on the positive results of the diagnostic test of tuberculin, the presence of tubercle bacilli in the sputum being subsequently ascertained. The examinations for tubercle bacilli in the sputum are not made at the dispensary, but the specimens of patients' sputa are sent to the medical officer of health of the local authority in whose area the patients reside, who examines and reports upon the specimens. We observed that in the majority of cases the actual report made by the medical officer of health was not annexed to the case-papers, but the circumstance that tubercle bacilli were present was recorded on the clinical case-sheet.[3]

---

[2] Dr. Wilkinson states that the technique as described was used by him in Australia 12 years ago, but that it has long since been superseded by an improved technique. According to the information furnished to us by Dr. Cooke the technique conducted at the tuberculin dispensary is as described in our report.

* Dr. Wilkinson states that the paragraphs marked with an asterisk are inaccurate and misleading. The statements therein were furnished to us in reply to our questions to Dr. Cooke. We were given to understand that Dr. Cooke was fully acquainted with the methods of Dr. Wilkinson and had had several years' acquaintance with his practice.

In only a limited number of cases are the results of subsequent examination made for tubercle bacilli recorded, and we should have preferred to see reports on the sputum made more frequently and a statement as to the presence or absence of tubercle bacilli in the sputum made at the termination of each course of treatment. This latter statement is only furnished in a minority of cases. The clinical details supplied in connexion with the cases are meagre. We append a specimen of the clinical case-sheet which is in use at the Tuberculin Dispensary. This case-sheet is not used for all the cases submitted to us. In lieu thereof a brief note as to the condition of the patient on initial examination is given. Patients attending the dispensary have the history of their illness recorded and a note is made as to the physical condition, state of the disease, and signs present at the initial examination. Each patient

---

[3] This statement is made for the purposes of accuracy, and we have not desired in any way to imply that we doubted the fact that tubercle bacilli were present in every case submitted to us in the investigation.

TABLE I.—*Detailed Analysis of Cases in Stage I. of Pulmonary Tuberculosis.*

No.	Name of patient.	Age.	Duration of treatment.	Initial dose in c.cm.	Final dose in c.cm.	Initial weight.	Final weight.	Stage of disease.	Remarks.
1	F. B.	18	9/6/1912–8/3/1913	0·005 P.T.O.	0·65 O.T.	10 st. 2½ lb.	9 st. 12½ lb.	I.	Medically examined twice. Went to Australia.
2	E. B.	22	13/12/1912–22/2/1915	0·005 P.T.O.	1·0 O.T.	7 st. 1 lb.	7 st. 4½ lb.	I.	Examined three times.*
3	J. B.	57	26/5/1911–23/12/1912	0·005 P.T.O.	0·1 O.T.	11 st. 11½ lb.	13 st. 5 lb.	I.	Given 0·001 c.cm. old T. and then 0·005 c.cm. for diagnosis, –7 reaction 100° F. Slight p.s. one apex.
4	F. By.	43	30/1/1913–15/6/1913	0·005 P.T.O.	1·0 O.T.	7 st. 7½ lb.	7 st. 9 lb.	I.	Examined once at onset, O.T. test. No note of details of final examination, but said to be apparently quite well.
5	Mrs. C.	22	6/6/1910–19/2/1915	0·005 P.T.O.	0·03 O.T.	8 st. 2 lb.	9 st.	I.	Three examinations. Disease extended. "Very well, September, 1920."
6	S. J.	23	18/10/1912–7/4/1913	0·005 P.T.O.	1·0 O.T.	7 st. 6 lb.	7 st. 6¾ lb.	I.	Brompton Hosp. T.B. became absent. Died Nov. 16th, 1916, kidney disease and pneum. (?).
7	Mrs. J.	33	5/6/1910–25/7/1911	0·005 P.T.O.	0·425 O.T.	7 st. 10 lb.	7 st. 11⅞ lb.	I.	No details of second examination July, 1920.
8	A. L.	30	12/9/1912–27/10/1913	0·005 P.T.O.	1·0 O.T.	10 st. 11 lb.	11 st. 6½ lb.	I.	Details of second examination, "keeping well"; July, 1920, second course of tuberculin; no details in 1913.
9	W. M.	39	9/1/1913–10/10/1914	0·005 P.T.O.	0·2 O.T.	13 st.	12 st. 7 lb.	I.	Increase in p.s.; hæmoptysis June, 1920. "Keeping well."
10	R. P.	14	30/4/1912–21/8/1919	0·005 P.T.O.	3·0 O.T.	5 st. 13 lb.	9 st. 1¾ lb.	I.	Well and at work 1920.
11	M. R.	25	20/5/1912–7/11/1912	0·005 P.T.O.	1·0 O.T.	8 st. 13½ lb.	9 st.	I.	O.T. test. Went abroad and lost sight of; no record of second examination; hæmoptysis.
12	M. S.	26	5/7/1912–12/5/1915	0·005 P.T.O.	1·0 O.T.	6 st. 3 lb. 12 oz.	6 st. 4½ lb.	I.	Several courses. August 4th, 1920, still stage I.; both lungs. Further short course, O.T. test.
13	J. S.	15	29/11/1912–10/2/1913	0·005 P.T.O.	0·575 P.T.O.	6 st. 8½ lb.	7 st. 7 lb.	I.	No details of subsequent examination; hæmoptysis; O.T. test.
14	K. W.	21	8/8/1912–10/3/1914	0·005 P.T.O.	1·0 O.T.	7 st. 10¾ lb.	8 st. 2 lb.	I.	T.B. absent in course of treatment. Lost sight of.
15	G. W.	?	12/5/1911–23/2/1912	0·075 P.T.O.	1·6 T.A.F.	9 st. 13 lb. ¾ oz.	9 st. 7 lb.	I.	Previous treatment at Knightwick Sanatorium. No record of physical examination.
16	J. Y.	21	20/1/1913–8/9/1913	0·005 P.T.O.	1·0 O.T.	11 st. 1¾ lb.	11 st. 11¾ lb.	I.	No details of subsequent physical examination. Went to Sydney, "well," 1917.

* In the draft report we stated we judged from the notes of this case that the disease from early infiltration progressed to cavities in both upper lobes, and that the patient was therefore in stage III. of tuberculosis at the end of treatment. Dr. Wilkinson maintained, however, that the patient was still in stage I. and that we had mistaken the rough delineation of the affected area for cavities. As mentioned in the text of the report, the cases considered have been classed according to the stage of disease in which they are in at the beginning of the course of tuberculin treatment. This stage is not necessarily the one in which the patient should be grouped at the termination of treatment and, from the evidence of the notes, it was apparently not so in this particular case. In deference, however, to Dr. Wilkinson's protest we eliminate the comment from the published report.

TABLE II.—*Classification of 107 Patients who have Undergone the Complete Course of Tuberculin Treatment, According to the Stage of Pulmonary Tuberculosis at Onset of Treatment and the Year in which they Commenced Treatment: Their Subsequent Fate Being Recorded in Ensuing Years up to 1920.**

on an average appears to be only once or twice clinically examined during the course of treatment. It may be that the patient has beer more frequently examined, but if so the results of such examination have not been recorded on the case-papers. We should have preferred to have seen a careful and complete record of the physical condition present in each patient at the termination of the course of tuberculin treatment. In a number of cases there is no record of the patient having undergone such an examination. Instead the statements are made that "the patient is keeping well," or "is apparently quite well," or "is well and at work" at the termination of a course of treatment.

With regard to the temperature records, the temperatures have been taken and recorded by the patients themselves four-hourly. This procedure, inevitable, however, for the dispensary method of treatment, is not free from the criticism that the patient may make an erroneous record or that his anxiety to appear to be doing well may lead him to record a lower temperature than that given by his thermometer. In certain of the charts also there are gaps, the patient forgetting to take his temperature or being away, and not recording his temperature for a number of days. The doses of tuberculin given are clearly shown on the charts, but in a number of cases the patient has had several successive courses of treatment, and we have experienced some difficulty occasionally in differentiating between a second rapid course of tuberculin and a prolonged single course of tuberculin treatment. The absence of full and concurrent clinical notes on the progress of the case has further hampered us in the detailed examination of the temperature charts.

We cannot refrain from the criticism that on the grounds stated above the evidence furnished by the case-records is not so full and complete as is desirable to satisfy a scientific tribunal, and that in the majority of the cases submitted to us the claim that the patient has improved or is "well" as the result of treatment depends upon the statement to this effect of the medical officer in charge of the case and is unsupported by detailed clinical evidence. Many of the temperature charts exhibit high reactions after the injection of the dose of tuberculin and in certain cases, notably those of C. (Stage II.–III.) and B. (Stage III.) the injections of tuberculin appear to have led to the disease becoming extremely active with a rapidly fatal issue.

Clinical Examination of Patients.

Dr. Camac Wilkinson kindly arranged for us to see several cases of tuberculosis which were undergoing or had undergone treatment with tuberculin at the Tuberculin Dispensary. We saw and examined 12 cases suffering from either pulmonary tuberculosis, laryngeal tuberculosis, or tuberculous glands. In three of the cases the disease appeared to be quiescent; these cases were of the chronic fibrosed type such as may be seen in any out-patient department for tuberculosis. In others the disease appeared to be still active. Although this activity was indicated by the progress and character of the pulmonary signs, dyspnœa, increased pulse-rate, and other constitutional symptoms, yet these patients appeared to have been educated by increasing doses to tolerate large doses of tuberculin without manifesting a reaction in temperature. In such cases, therefore, the patient appeared to be immunised against the effects of large doses of tuberculin rather than against the effects of his tuberculous lesion.

5. *Analysis of the Records.*

(Number of cases, 107.)

The cases have been grouped according to the Turban-Gerhardt system of classification into three stages; the patient is classed, according to the stage of disease which he is in at the beginning of the course of tuberculin treatment. As already observed, the clinical notes are not copious enough to determine the patient's stage of disease at the end of the period of treatment in every case. In all the cases tubercle bacilli were stated to be present in the sputum.

Number of Patients Treated in Each Stage of the Disease (total, 107).

Stage I.	16	Stages II.–III. ..	27
Stage II.	34	Stage III.	30

Longevity of Cases.

The 107 patients reviewed by us commenced treatment in the years 1910, 1911, 1912, and 1913; 4 patients commenced treatment in 1910, 37 patients in 1911, 64 patients in 1912, and 2 patients in 1913. The majority of the patients therefore commenced treatment in the years 1911 and 1912. In Table II. (Appendix) 107 patients commencing tuberculin treatment in the period 1910–13 have been classified according to the stage of disease and the years in which they commenced treatment, their subsequent fate, whether alive or dead, being recorded in ensuing years up to 1920.

The table may be summarised thus with regard to the fate of these 107 cases as ascertained by the year 1920. Of 16 cases in Stage I., treated in 1910–13, in 1920, 8 were known to be alive, 1 to be dead,[4] and 7 were lost sight of. Of 34 cases in Stage II. treated in 1911–12, in 1920, 15 were known to be alive, 13 to be dead, and 6 were lost sight of. Of 27 cases in Stages II.–III. treated in 1910–12, in 1920, 4 were known to be alive, 16 to be dead, and 7 were lost sight of. Of 30 cases in Stage III. treated in 1910–12, in 1920, 1 was known to be alive, 19 were dead, and 10 were lost sight of. Of 107 cases in all stages of the disease treated during the period 1910–13, in 1920, 28 were known to be alive, 48 were dead, and 31 were lost sight of.

These figures cannot be said to demonstrate any striking influence of tuberculin upon longevity. The cases that live longest are those in which the disease is recognised earliest, which corresponds with the usual figures of longevity in tuberculosis, quite apart from any special method of treatment. In 100 of the patients figures are available as to age and sex. There were 63 males and 37 females. Of known survivors in 1920, 18 are males and 10 females, 10 males being over 35 years of age at the initiation of treatment and 5 females over 35 years of age. This mature age of the majority of the survivors suggests a chronic fibrosed type of case which, in ordinary circumstances, usually survives for a considerable length of time, and this suggestion appears to be supported, so far as the records indicate, by the clinical description of the cases. From this aspect, again, we fail to find any preponderating influence played by tuberculin treatment in prolonging the life of patients. Analysis of the figures therefore furnishes little justification for the claim that by this tuberculin method of treatment the lives of patients are prolonged to a far greater extent than by other methods of tuberculosis treatment.

It is within the experience of all of us that patients suffering from pulmonary tuberculosis with tubercle bacilli in their sputum or patients suffering from genito-urinary tuberculosis with tubercle bacilli persisting in the urine may live with other forms of treatment for a considerable period of years.

Conclusions.

1. The evidence submitted by the Tuberculin Dispensary League as to the results of the treatment of tuberculosis by tuberculin is not so full and satisfactory as is desirable in an investigation of this character. The cases are limited in number and the clinical evidence supplied in relation to them is meagre.

2. There is no doubt that this method of tuberculin administration succeeds in immunising patients to large doses of tuberculin, but there is no evidence that it also immunises them to tuberculosis. Indeed, there is distinct evidence to the contrary, for the majority of patients after an initial course of tuberculin treatment have manifested signs of active tuberculosis and have had to undergo subsequent courses of tuberculin treatment. Also, certain patients in the intermediate stage of tuberculosis have died with signs of active disease, although they had recently tolerated large doses of tuberculin.

---

[4] This patient is stated to have died four years after treatment of nephritis and pneumonia.

3. The most favourable results relate to the 16 cases in Stage I. (Turban-Gerhardt), of whom only one is known to be dead, while eight were stated to be alive and well in 1920 (Table II.). In stating this we cannot assume that the patients were treated solely by tuberculin and underwent no other special method of treatment, for one patient is specifically stated to have undergone treatment at Knightwick Sanatorium and another was an in-patient at Brompton Hospital. There is reason to believe also that a certain number of patients who attended the Tuberculin Dispensary have at one time or another been under treatment at various institutions where they have learned the various forms of hygienic treatment of their disease. In the intermediate and advanced stages of the disease the results of tuberculin treatment are less favourable and therefore the recognition of tuberculosis in the early stage and the placing of the patient under hygienic conditions of life probably rank as equal with, or more important factors than, tuberculin treatment alone in the arrest of the disease. Also, the number of cases in the first stage (16) is too few to enable a general conclusion to be drawn as to the efficacy of tuberculin treatment for cases in this stage.

4. The longevity of cases treated by this tuberculin method is equally seen in cases untreated by tuberculin, and the mature age of many of the survivors is indicative of a chronic type of pulmonary tuberculosis which in ordinary circumstances, apart from any special form of treatment, usually allows survival in the individual for a considerable length of time.

5. Occasionally, there would seem to be individual cases of pulmonary tuberculosis which derive distinct benefit from tuberculin treatment. There is, however, always the risk that large doses of tuberculin may light up latent foci of tuberculous disease, and we deprecate the continued administration of tuberculin after the temperature reactions and constitutional disturbance have indicated renewed activity of the disease. In such cases there is undoubtedly risk that continuance of tuberculin administration may accelerate a fatal termination.

6. For the reasons given above, we are of opinion that the method of tuberculin administration advocated by the Tuberculin Dispensary League does not appear to have claims over other methods of treating tuberculosis, either with or without tuberculin, which would justify its general adoption.

BRITISH MEDICAL ASSOCIATION:

THE COUNCIL DINNER.

THE second annual Council dinner of the British Medical Association was held at the Hotel Victoria, London, on Oct. 24th, Prof. R. A. Bolam, chairman of Council, presiding. The dinner was made the occasion for special congratulation to Sir Dawson Williams, the editor of the *British Medical Journal*, who has just completed 25 years in the editorial chair. Among the guests present were—

Sir William Joynson-Hicks, the Minister of Health; Lord Justice Atkin; Sir Humphry Rolleston, President of the Royal College of Physicians of London; Sir John Bland-Sutton, President of the Royal College of Surgeons of England; Sir Charters Symonds; Sir William Hale-White, President of the Royal Society of Medicine; Sir Dawson Williams; Lord Dawson; Sir John Collie, M.P.; Sir S. Squire Sprigge; Dr. T. Watts, M.P.; Dr. A. Bostock Hill, President, Association of County Medical Officers of Health; Major-General J. B. Smith, President, India Office Medical Board; Sir Henry Craik, M.P.; Surg. Rear Admiral J. Chambers, R.N., Director-General Royal Navy Medical Service; Sir Arthur Robinson, First Secretary, Ministry of Health; Lieut.-General Sir W. B. Leishman, Director-General, Army Medical Service; Sir George Newman, Chief Medical Officer, Ministry of Health; Air Commodore D. Munro, Director, R.A.F. Medical Service; Dr. T. W. Naylor Barlow, President, Society of Medical Officers of Health; Sir Sydney Russell-Wells, M.P.; Sir George Makins; Sir Jenner Verrall; Dr. Molloy, M.P.; Sir John Atkins; Sir James Dundas-Grant; Sir Edwin Lutyens, R.A.; Sir William Macpherson; Sir Alfred Rice-Oxley; and Sir Leonard Rogers.

The toast of "The Common Health" was proposed by Mr. C. P. Childe, the President of the Association, and was replied to by Sir W. Joynson-Hicks and Sir William Hale-White. Mr. Childe showed by the striking figures which he adduced how vast had been the improvements in common health during the last century, but he urged the medical profession to come more prominently into public life, and to secure better representation in Parliament and upon the boards of municipal and county authorities. The Minister of Health, in an eloquent reply, proved by a still more striking series of figures what a huge economic loss to the country was implied in time wasted through ill-health. But the State and the medical practitioner, he said, must coöperate against the fell diseases and foul conditions which still obtained, causing agony in the home. Sir William Hale-White, who also replied, pointed out that he was responding to a toast whose cordial acceptance would be unchallenged. Men differed on matters of creeds, political ideals, and national boundaries, but were unanimous in their desire for health.

The toast of the evening, "Our Editor," was proposed by Sir John Bland-Sutton, who sketched Sir Dawson Williams's career as pathologist and clinician and later as editor, being able to do so at each step on personal knowledge extending over 40 years. Sir Dawson Williams, who was received with acclamation, said that he seemed to have been enjoying the privilege of hearing his own obituary notice. He referred to Bland-Sutton as one of the founders of comparative pathology, who might have been pure man of science or physician but who elected for surgery. The distinction between medicine and surgery, said Sir Dawson Williams, had recently been defined for him by a lady in the following words: "The physican gives you something to take in, while the surgeon takes something out of you." Alluding to his earlier work at the *British Medical Journal*, he said that he was associated with Ernest Hart, "the quickest-witted man he ever knew," who had been trained under Thomas Wakley "who sowed wild oats with both hands" when starting THE LANCET, whose centenary they had just had the pleasure of celebrating. After a brief description of the development of the British Medical Association during his long connexion with it, Sir Dawson Williams concluded his speech by quoting the words used by Prof. Starling in the last Harveian oration, in which the belief was affirmed that the physician of to-day is seeing not a renaissance, but a new birth of man's power over his environment. In reference to the impending change of headquarters from the Strand to a beautiful building in Bloomsbury, the speaker said that in their new home they would be able to hold dinners and receive guests, and that plate would be necessary, towards which he begged to contribute a snuff-box.

The toast of "The Guests" was proposed from the chair and replied to by the Lord Justice Atkin and Sir Humphry Rolleston. Dr. Wallace Henry, giving the toast of the chairman, said that Prof. Bolam's work in bringing about a linkage between the Association and the Society of Medical Officers of Health, and in securing Sir Edwin Lutyens's beautiful building as their new headquarters had earned the gratitude of all.

LADIES' MEDICAL GOLFING SOCIETY.—The autumn meeting was held at Denham Golf Club on Oct. 25th. The results of the various competitions were as follows: Scratch prize: Mrs. Granger Harrison, 89. Captain's prize for best net score in either division: Mrs. Jennings, 97 – 22 = 75. Second prize (juniors), Dr. Joan Ross, 101 – 21 = 80. First and second senior handicap prizes: Lady Goadby, 96 – 14 = 82; Mrs. Cavendish Fuller, 94 – 10 = 84 respectively. Prize for best 16 holes: Mrs. Nicholson, 68. Foursomes v. bogey: Miss Smyth and Lady Goadby, 1 down.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 3, 1923.

THE HEALTH OF THE SCHOOL CHILD.

SIR GEORGE NEWMAN'S report [1] on the school medical service for the past year is reassuring. While it deplores the fact that the need for financial restriction should have arrested certain developments almost at their birth, assurance is given that this is but a temporary phase and that the machinery so laboriously built up by local education authorities in previous years, though for the moment denied further expansion, has not been seriously damaged nor, taking the country as a whole, appreciably slowed down. "It remains intact," Sir G. NEWMAN writes, "and ready for increased output directly circumstances permit." The extraordinarily rapid growth of medical work among school-children, its detailed comprehensiveness, its ramifications which have now insinuated their way into every phase of educational life are a tribute to the persevering energy of the Board of Education and to the efficient administration of its medical service. Ten years ago the only statutory obligations on local education authorities in connexion with medical services were to provide medical inspection for children in elementary schools and to secure appropriate education for the blind and deaf; special provision for mental defectives, and medical treatment of the elementary school child were then entirely optional. It was in 1914 that the obligation was placed on authorities to provide for mentally defective children, and in 1918 this obligation was extended to physically defective children. Every authority is now obliged to make provision for medical treatment, and the school medical officer has found his way into secondary schools and other places of higher education. Out of an average of well over five million children attending elementary schools in England and Wales 46 per cent. were medically inspected during the school year; we are told that about 40 per cent. of the children were found suffering from a greater or less degree of physical defect, quite apart from disability due to infectious disease. About 2 per cent. of our elementary school population suffer from definite malnutrition, heart disease, anæmia, or deformities; in the country as a whole this means 100,000 victims of each of these four conditions. Among the infectious diseases prevalent during 1921 the highest mortality was attributable to diphtheria, whooping-cough, measles in descending order, while in the past year whooping-cough came first, measles second, and diphtheria third. Measles and scarlet fever, however, are still the greatest enemies of child life on account of their remote results.

Considerable progress has been achieved in dealing with cripple children. The science and art of orthopædics made great strides during the war. Crippling is obvious to the eye, and the growth of public interest in this type of defect has been stimulated energetically all over the country with the result that its treatment, thanks to the help of enthusiastic voluntary agencies, is going steadily ahead. Sir G. NEWMAN points out, however, that to deal satisfactorily with the problem of the cripple child early ascertainment of defect is essential. The incidence is largely prior to school life and occurs at any time up to 5 years from infantile paralysis, rickets, or non-pulmonary tuberculosis. He regards the physical condition of the pre-school child as still one of the most urgent problems of public hygiene, and devotes considerable space to the subject in the report. The first 12 or perhaps 18 months of the child's post-natal existence are passed under the watchful eye of the local health authority. The child attends the infant welfare centre periodically or is seen at home by the health visitor, but from this age until he enters school at 5 years, beyond a sporadic visit or two to the welfare centre, there is no further supervision of health. The age-period of 2 to 5 has been aptly described by one school medical officer as No-Man's Land. "The fact is," Sir G. NEWMAN writes, "that after the first year of life the young child has to bear a heavy burden of environmental neglect associated with bad housing, poverty, and absence of hygienic supervision. As a result the school medical service is faced with the hard issue that out of an infant population born healthy 35 to 40 per cent. of the children who are admitted to school at 5 years of age bear with them physical defects which could have been either prevented or cured . . . Here we have the most serious and wasteful defect in our national health service." This is surely a grave indictment of our present public health system and steps should be taken at once to remedy an acknowledged ill. Recent observations have shown that the earliest period of physical growth is the most important, for seeds of disease sown when resistance is slight may establish themselves beyond hope of removal. Over 12 years ago Dr. C. J. THOMAS, a medical officer to the L.C.C., demonstrated from carefully-sorted data that growth and capacity go hand in hand, and that the earlier the child contracts disease the greater the total effect produced. In this report we have the medical officer of the Board of Education emphasising the importance of these findings in a table comparing the heights and weights of London school-children in 1905 and 1923. It is found that the 8-year-old child in the selected area is three and three-quarters of a pound heavier and half an inch taller to-day than the child of the same age in the same area 15 years ago. Here is proof of the amazing cumulative effect of education and social effort.

Sir G. NEWMAN calls for more coördination between the medical officer of health and the school medical service. Here by joining hands a quite unnecessary gap may be bridged. The two to five-year-old period requires careful individual study; it cannot be tackled by the methods of the infant welfare centre. The child is now a separate entity from the mother; another baby has probably taken its place, and being less dependent it is left more to its own devices. It is going through a period when mental development is following closely in the wake of physical development; without the physical there can be little mental development, and physical arrest implies restricted mental growth. Here is a stage where doctors and educationists must work together, each pulling his own weight, the educationist directing the child's development by skilfully-planned coördination of muscular and mental activities, the doctor keeping a watchful eye on the child's general health and hygiene. The nursery school which has evolved out of the old-fashioned day nursery is the only place to-day where this work is being done in unison, and the number of nursery schools—24 for the whole of England and Wales, accommodating little over 1000 children altogether—is lamentably small. It is to be hoped that the Board will relax the financial stringency under which proposed schemes for dealing with this problem are languishing to-day. A scheme should be devised which, in Sir G. NEWMAN'S words, "shall be elastic enough to comprise all children of pre-school age in need of assistance." Another problem urgently awaiting administrative solution is that of the dull and backward child. All schemes to deal with established defects cost money; all are relatively expensive. To tackle the problem of the pre-school age is to diminish the number of cripples, and is sound financial policy. In 40 per cent. of the dull and backward children in the schools the unfortunate condition, according to the report, is accounted for by extraneous or non-mental factors, and it must be apparent that the earlier these conditions are investigated and courageously taken in hand the greater the saving in future expenditure. The report ends on an optimistic note. There is evidence throughout its pages of serious efforts being made to coördinate and consolidate social effort. It is the most constructive and encouraging document which has yet emerged from the medical department of the Board of Education.

THE NEXT STEP IN THE PANEL CRISIS.

THE situation in regard to the future of the insurance medical service has altered essentially during the past week as the result of correspondence between the Minister of Health and the Medical Secretary of the British Medical Association, set out on another page. The Minister has expressed his willingness to submit to the Cabinet a proposal to appoint a Royal Commission to consider the whole subject at an early date, and to remit to this Commission the question of remuneration. This offer will give the medical profession the desired opportunity of putting their views fully before the public in an orderly manner, while the Minister's willingness to accept such an inquiry indicates that the economic side of contract medical practice as at present administered is in need of full and intimate investigation. "I am not enamoured of the panel system," writes the present Minister, expressing a personal view other than that of some of his predecessors, who regarded this system as a basis on which an efficient medical service could be built up for the mass of the people. A new and specious point has been raised from the actuarial side, for the Minister contends that he cannot draw upon the reserves of insurance money, however great, because they have been built up by payments from the young and healthy people, who will claim the money in their later years when sickness is heavy. It needs the atmosphere of public comment, consequent on the findings of a Royal Commission, to deal with points like these freely.

The offer of a Royal Commission by the Minister does not immediately ease the present situation. As an impartial review of the methods and results of administering all the benefits provided by the Insurance Acts during 10 years' working it will certainly be welcomed by the doctors. Such a review could not fail to stimulate the Ministry to develop and complete the medical service in order to give to the community a real return for the money expended. The panel system at present, it must be admitted, is only half a service, and we are in sympathy with the remarks of the chairman of the Marylebone division, reported on p. 1004, in which he contends that the national health insurance must remain incomplete until the hospitals with their great resources form a part of it. It will be a great day for the hospitals, he says, when their special services are so required. This is also the view of the British Hospitals Association. Reference to a Royal Commission could hardly fail to result in the extension of the medical service in many directions in which it is now incomplete, and to which we have pointed so many times. Means of diagnosis, consultant and specialist services, practitioner clinics, are some of these needs yet unsupplied. But the settlement of the immediate difficulty of the position lies very largely in the hands of the Minister himself. An emphatic declaration from him to the effect that insurance funds as a whole are administered by the department, and that the sickness benefit fund controlled by approved societies is distinct from the medical benefit fund administered by insurance committees, would in itself go far to ease the situation. The Minister has been reported on one occasion as saying that there are only two ways of paying the doctors more than 8*s*. 6*d*.—either the money comes out of the taxpayers' pockets or out of that of the insured persons. "The doctors must remember that when I have made an agreement with them I have still to make an arrangement with the approved societies." And on another that the money belongs to the State, "and, as I am the representative of the State, it is my money." It all seems very disquieting, and the position is clearly a legacy of the arrangement made in 1922 when the Treasury grant was abolished and a portion of the present capitation fee taken out of surplus funds revealed by the first valuation of the societies.

The professional position in the dispute is quite clear. The doctors believe that the insurance fund is in a position to honour the claims made upon it, and that the medical benefit portion of that fund should be adjusted so as to provide the fee which after (not before) negotiation is considered adequate to ensure an efficient service. The position of the approved societies is equally clear. They declare that they have no further interest in the dispute if they can be assured that their sickness benefit funds are not to suffer as the result of any award to the doctors. The position of the Minister is not so clear. "Control" may be difficult to define, but the fear of control of their service by the approved societies has been sufficient to unite, not panel practitioners alone, but all sections of the medical profession, in a common act of refusal. We set out in another column the steps by which this insidious process may arise, a process which, like an early cancer, gave rise to little pain or discomfort in its initiatory stages, but which, if not dealt with, is likely in its course to sap the strength of the whole organism. It is easy to assert or contradict the presence of a malignant growth in the early stage. The mere hint of outside control has at any rate been sufficient to cause alarm among those who regard the doctor's responsibility to his patients and to the State as an asset of paramount importance. A pledge from the responsible Minister that this fear is ill-founded is the one thing needed. No one would wish to operate on a neoplasm whose existence had been categorically denied by a trusty and competent pathologist. We can only hope that, in the course of further negotiations, the position may be made so clear and certain that the profession will feel secure in rendering service to the Ministry and through the Ministry to the community at large. The result of the pourparlers now taking place will possibly be known to our readers before this reaches them.

THE EXPERT WITNESS.

In a popular statement of the degrees of untruthfulness the superlative is reserved for the expert witness. When scientific evidence adduced by plaintiff and defendant seems to be mutually contradictory, the layman is puzzled and grows sceptical of scientific values. Indeed, when in some big criminal trial the case for the Crown is supported by an overpowering weight of technical authority, he is inclined to assume that an equal volume of authority would be forthcoming for the defence if the defence were organised on the same scale and with the same resources. It might help to preserve the dignity of science amid the rough-and-tumble of the law-courts f a system of scientific referees were developed on the ines of the nautical assessors in Admiralty cases, as recently suggested by Mr. C. AINSWORTH MITCHELL n his interesting little book "The Expert Witness."[1] But already the County Court, the High Court, and the Court of Appeal possess wide general powers of summoning the aid of qualified assessors in all sorts of matters, apart from the special powers given by he Employers Liability Act and the Patents Act. Judges have shown less inclination to use these powers than might have been expected. It is perhaps natural that courts should be slow to delegate their udicial functions; often, too, the scientific issues in a case are but a part of what requires to be viewed as a whole.

Approaching from another side the task of saving scientific witnesses from undignified situations, the British Medical Association at its Portsmouth meeting last July passed a motion recommending hat medical men called as witnesses in legal cases especially under the Workmen's Compensation Act) hould consult with each other before the case is heard, so that they may, if possible, agree upon facts. The kind of incident which inspired this motion is llustrated by a street accident claim at Birmingham Assizes, where the plaintiff's medical witness deposed hat the photographs showed a fracture of the skull, whereas another witness, the radiographer, presently tated, on the contrary, that the lines relied upon in he photograph represented blood-vessels and not the ines of a fracture. Discrepancies of this nature, in o far as they can be foreseen before the trial actually begins, could presumably be cured by closer preiminary attention to points likely to be controversial nd by obtaining further photographic negatives to emove doubts or obscurities. Desirable as it may be n the abstract, we are not sanguine of the prospects f the procedure recommended. By all means let ll the cards be placed on the table. The public, however, and its legal advisers have yet to be educated p to perfect altruism in litigation; the parties to n action will, we fear, be suspicious of anything which can possibly be misconstrued as fraternising with the enemy in the trenches opposite. If a medical eport about a plaintiff's physical condition is to be ommon property, the doctor who has to set pen to aper may find himself exposed to all kinds of subtle ressure as to the limits of what he is going to say. One can even imagine the suggestion that the doctor's eport had better be settled in counsel's chambers. t is clearly desirable that the general value of rofessional testimony should not be impeached by ncidents which mislead laymen into the cynical iew that plaintiff and defendant can always find medical experts who will support their respective ases at all costs.

But even if all the material facts in a case can be agreed beforehand, there will still be discrepancies as to the opinions to be based upon those facts. When in a street accident case the full tale of the plaintiff's broken bones and bruises is told, we cannot expect the expert witnesses on both sides to agree upon the degree or duration of traumatic neurasthenia, except by some form of compromise which more properly belongs to the mental processes of a jury. The elimination of controversy between professional witnesses in such a case—whether attained by preliminary agreement or by the employment of scientific assessor or referee—would have obvious advantage. The value of the combination of legal and medical qualifications in the person constituting the judicial tribunal is often recognised when coroners are appointed. No doubt the doctrine of judicial ignorance prevents other judicial officers from acquiring for themselves and applying in the public interest a suitable measure of scientific knowledge. Perhaps a future generation will insist that, for the purposes of Workmen's Compensation, every county court judge should be a fully qualified medical practitioner, as well as, for the purposes of the Rent Restriction Acts, a fully qualified architect and surveyor. Some day we may even see an official medical representative appointed to the County Court Rules Committee. Meanwhile medical witnesses can play their own part in upholding the reputation of scientific evidence. They can give their evidence both in criminal and in civil cases with restraint and caution and with as much impartiality as the lawyers on both sides permit. The calm of the judge is a better model than the heat of the advocate.

◆

THE CENTENARY DINNER OF "THE LANCET."

A DINNER in celebration of the centenary of THE LANCET will be held in London on the evening of Thursday, Nov. 29th, at the Hotel Victoria, Northumberland-avenue, London, W.C., at 7.30 for 8 P.M. Sir Donald MacAlister, President of the General Medical Council, will take the chair, and will be supported by the Presidents of the Royal Society, the Royal Colleges of Physicians of London, Edinburgh, and Dublin, the Royal Colleges of Surgeons of England, Scotland, and in Ireland, the Chief Medical Officer of the Ministry of Health, the President of the British Medical Association, and the Presidents of the Royal Society of Medicine and of the Medical Society of London. The Minister of Health has signified his intention of being present, and it is hoped that a gathering representative of all the interests associated with the medical profession will meet on this occasion. Those who desire to be present should communicate before Nov. 15th with Mr. H. D. Gillies or Dr. J. H. W. Laing (hon. secs.) at 7, Portland-place, London, W. 1.

The charge for the dinner has been fixed at 15*s.*, exclusive of wines, and if notice be given in advance endeavour will be made to arrange that friends who so desire shall sit together.

ROYAL EAST SUSSEX HOSPITAL.—On Oct. 23rd Princess Alice opened the new building erected in Cambridge-road, Hastings, overlooking the sea. The institution at White Rock, founded some 83 years ago, had outgrown the demands made upon it, but when the new site was presented to the hospital by a committee in memory of King Edward VII. it was not expected that such a long interval would elapse before the new hospital was opened. The foundation-stone was laid on July 15th, 1914, but the war put a stop to the building operations. It was eventually decided to include the new hospital in the war memorial fund, and as a result the total cost of the new hospital for 105 beds—namely, £120,000—has been covered. The hospital is now to be known as the Royal East Sussex Hospital.

Annotations.

"Ne quid nimis."

THE DIRECTOR OF THE NEW SCHOOL OF HYGIENE.

The selection of Dr. Andrew Balfour for the post of first director of the School of Hygiene endowed by the Rockefeller Foundation will cause no surprise, since his unique qualifications for the post are sufficiently obvious. We expressed a belief last month when recording his resignation from the Wellcome Bureau of Scientific Research, which he has directed for ten years, that his period of unemployment would be short, and indeed it has proved so. Dr. Balfour has had a brilliant academic career at Edinburgh and Cambridge, where he was a prominent member and afterwards captain of the football team, He also gained his Scottish international colours. He served in the South African War as civil surgeon and was director of the Wellcome Tropical Research Laboratories in Khartoum from 1902–1913. During the Great War Dr. Balfour acted as sanitary adviser to Headquarters in Egypt, Salonika, Mesopotamia. India, and Africa. His reports on the health conditions of that period are of first-rate importance. In 1918 he undertook the investigation of the organisation of the public health services for the Egyptian Government and his report on the health problems of Mauritius followed on a visit to the island in 1921. At the Wellcome Bureau and elsewhere Dr. Balfour has himself undertaken much valuable research, notably on the spirochætosis of relapsing fever, blood conditions, and bacteriological problems connected with sanitation. He is joint editor of Lewis and Balfour's "Public Health and Preventive Medicine" and has published a number of monographs in connexion with sanitation in the tropics. The choice of a director of an institute established for teaching and research is analogous in some respects to that of a Prime Minister, for on the wisdom shown in this initial appointment depends the formation and later the cohesion of the team of associate workers. Honesty of purpose, skill in administration, knowledge of men—all these are indispensable in the head of a State or of a research intitute, but the latter must also possess considerable scientific standing if he is to attract fine colleagues. We congratulate the committee on having chosen a man under whose general direction distinguished specialists will be proud to work.

THE STRUCTURE OF THE THYROID GLAND.

The appearance of diagrammatic simplicity which ordinary sections of the thyroid present has encouraged a belief that its essential structure is obvious and well understood. In the current number of the *Journal of Pathology and Bacteriology* (vol. xxvi., p. 459), however, Dr. G. Scott Williamson and Dr. I. H. Pearse bring forward a novel interpretation of its morphology. The familiar vesicle lined with cubical or columnar epithelium and filled with colloid is not, according to these authors, the unit of structure, but a mobile and transitory phase of functional activity. The fundamental unit is a lymphatic space or sinusoid in which long convoluted columns of syncytial epithelium float, richly covered with a plexus of capillaries and not continuous with one another. In their resting stage these epithelial columns are familiar as the interalveolar masses of undifferentiated epithelium lying between the colloid-filled vesicles. Activity takes place along two distinct lines. In the first, droplets of colloid appear at various places in a column and increase in size until its continuity is broken up by a series of tense vesicles of varying sizes round which the epithelium is rearranged; this process of "vesiculation" gives rise to the conventional typical appearance of the thyroid, but, in the view of the authors, it does not represent the real secretory activity of the gland. This is exhibited in the second process described as "lacunation" in which the epithelium swells, becomes granular and vacuolated, and then partly dissolves, the resultant fluid mass accumulating in relatively lax irregular spaces in the centre of the epithelial columns. At the same time the lymphatic space becomes more or less distended with liquid, and lymphocytes appear in the intralobular lymph channels. This secretory activity is present in very small amount in the average normal thyroid. Judging from the authors' description and figures it is represented more largely in Graves's disease, and we shall await with interest the extension of these new ideas to the interpretation of pathological changes.

FIFTH CONGRESS OF THE FAR EASTERN ASSOCIATION OF TROPICAL MEDICINE.

From Sept. 3rd to 8th the Fifth Congress of the Far Eastern Association of Tropical Medicine met at Singapore, under the presidency of the Hon. Dr. A. L. Hoops, principal civil medical officer of the Straits Settlements, and member of the Legislative Council. In his presidential address Dr. Hoops referred to the formless growth of cities, with the consequent overcrowding and dissemination of preventable diseases such as tuberculosis. Town planning, zoning, the building of houses, the provision of cheap transport, and of modern sanitary arrangements, must precede the destruction of insanitary tenements. Dr. Hoops continued:—

> Starvation is not common in the tropics. More malnutrition results from the use of improper food, and badly prepared food, than from lack of food. The three great deficiency diseases, beri-beri, scurvy, and rickets, are all preventable by proper diet, plus sunlight in the case of rickets. . . . The prevention of dental decay will avert the majority of digestive troubles to which flesh is heir. . . . In Malaya the rural population, amongst whom under-milled rice is the staple food, and breast feeding is almost universal, have good teeth. Amongst city dwellers, many of whom eat overmilled rice, or overmilled wheaten bread, and whose babies are often bottle fed, a sound head of teeth is the exception. Medical inspection of schools here during the past two years discloses that nearly two-thirds of school-children in Singapore city are suffering from serious dental decay, while the proportion in our rural schools in Province Wellesley is under 5 per cent Our large Eastern cities need pre-natal clinics, maternity hospitals, training centres for midwives, post-natal clinics child welfare activities—dispensaries and sanatoria for the tuberculous—venereal clinics, school and dental clinics But what will these avail, unless we remove the sources o evil—overcrowding and bad feeding? Good housing is a powerful agency in the suppression of that scourge of mankind—plague. In Assam the moving of inhabitants from infected houses to new quarters has greatly aided the diminution of kala-azar.

Dr. Hoops went on to deal specifically with malaria ankylostomiasis, beri-beri, and other diseases, all o which were the subjects of many papers and discussions during the Congress. Three hundred medical men representing 15 countries, were present, the Congress being the largest and most representative yet held A painful interest attached to the acceptance by the Association of the invitation to hold its sixth congress at the Tokio Imperial University, for many of the members of the strong Japanese delegation which delivered the invitation had left their families in Tokio and could hear no news of how they had fared during the earthquake. Among the social functions o the Congress was the laying of the foundation-stone o the Singapore Medical School, by Sir Laurence Guillemard, Governor of the Straits Settlements. A the final meeting of the Congress the following resolutions were adopted concerning uniform port quarantine procedure in the Far East:—

> 1. The regulations of the International Convention o Paris, 1912, are not suitable for the proper carrying out o quarantine measures in the Far East.
>
> 2. The division so far proposed by l'Office International d'Hygiène and the Office of Hygiene of the League of Nations do not alter this unsuitability.
>
> 3. That circumstances in the Far East demand a quit different quarantine procedure from that in Europe. It i

therefore desirable that a separate agreement should be drawn up to govern quarantine regulations in the Far East to allow of the necessary coöperation between the different Far Eastern countries. It is also agreed that a copy of this resolution be sent to all Governments of the Far East and the Office of the Health Committee of the League of Nations at Geneva, and l'Office Internationale d'Hygiène at Paris.

In regard to these proposals the Hon. Mr. E. A. Gilmore, head of the Health Service in the Philippines, had previously expressed the hope that the handling of the matter by the League of Nations Committee would not make it difficult for America to participate, and had suggested that a conference of the countries interested would be helpful. The Congress was felt to have been a great success, and the following week was spent by a number of the overseas members in touring the Federated Malay States and Penang.

PAINLESS MAXILLARY SINUSITIS SIMULATING PULMONARY TUBERCLE.

THE early diagnosis of pulmonary tuberculosis is of such fundamental importance that any febrile condition associated with cough and wasting must of necessity excite suspicion. It is a familiar fact to most physicians and laryngologists that pulmonary tuberculosis is often simulated both as to symptoms and physical signs by inflammatory conditions of the upper air passages, but it is open to question whether this fact is sufficiently generally recognised. An interesting paper by Dr. A. Lowndes Yates, which we publish in this issue of THE LANCET, should serve to draw attention to a special form of this problem—viz., maxillary sinusitis—especially in cases without empyema of the antrum and not associated with pain. Dr. Yates gives a brief résumé of the literature on the subject, and shows that since 1916 considerable attention has been paid to this question. He suggests that when the nasal protective mechanism fails and infective organisms reach the nose, in some patients the infection may stop short of producing empyema of the antrum and yet lead to reactive changes owing to the flow of pus into the pharynx and laryngopharynx. The delay in the removal of the infected mucus allows of toxic absorption, resulting in some cases in wasting and evening rise of temperature and night sweats. He describes in some detail the signs produced by such a condition. Apparently anterior rhinoscopy shows little or nothing, whereas posterior rhinoscopy may show very definite changes and more or less characteristic appearances may be seen in the pharynx and larynx. Dr. Yates finds that this condition may coexist with pulmonary tuberculosis, and in this combination the appearances are different. A point of interest and importance is that a patient with the painless form of maxillary sinusitis may be quite unaware of its existence, and may refer all his symptoms to his chest. Dr. Yates's observations would suggest that in any case in which cough exists with obscure signs in the chest, and in which repeated investigation of the sputum is negative, a careful examination of the nose and throat for maxillary sinusitis should be made. He gives such a clear description of the appearances found in this condition that his observations should be capable of easy confirmation or criticism. The subject is of special importance, as it may afford a means of excluding pulmonary tuberculosis without loss of time in some obscure cases, and lead to a more rapid restoration to health and comfort.

THE INCOME AND EXPENDITURE OF THE LONDON HOSPITALS.

THE annual statistical report for the year 1922 on the income and expenditure of 113 London hospitals, issued under the auspices of King Edward's Hospital Fund for London, has just been published.[1] The report is divided into five sections, each of which respectively gives in tabular form: (*a*) General particulars of the work done and the accommodation provided; an analysis of (*b*) the income, and (*c*) the expenditure; (*d*) the cost of working; and (*e*) group comparisons of the different hospitals. In this last section the hospitals are classified as (1) larger general hospitals, with and without medical schools; (2) smaller general hospitals; (3) consumption hospitals; (4) hospitals for women and children; (5) ophthalmic hospitals; (6) hospitals for epilepsy and paralysis; (7) cottage hospitals, and (8) lying-in hospitals. It is encouraging to note that in 1922 the total average number of available beds (12,421) in the 113 hospitals under review shows a net increase of 995 over the figures for 1913, although there has been a slight decrease since 1920. In-patients in 1922 numbered 162,149, a net increase of 17,511 over 1913. While the new out-patients in 1922 show a decrease of 48,000 as compared with 1913, the out-patient attendances have increased by 1,225,000. The average attendances of each out-patient were, in 1913, 3·5; in 1920, 4·3; in 1921, 4·2; and in 1922, 4·5. The income of these 113 hospitals (apart from special distributions) increased from £1,470,000 in 1913 to £2,401,000 in 1920 and £2,566,000 in 1921. In 1922 it decreased slightly to £2,398,000. It must be remembered, however, that the special distributions which are omitted from these figures included in 1922 £243,000 from voluntary sources—viz., from the first and second instalments of the proceeds of the combined appeal. It was part of the scheme of this appeal that for an agreed period the coöperating hospitals should suspend all independent appeals. It was anticipated therefore that, other things being equal, the income from voluntary sources would be below the normal if the proceeds of the combined appeal were excluded, and above the normal if they were included. The difficulties of the hospitals, as compared with conditions before the war, were produced by increase of expenditure and not by decrease of income. That expenditure now shows a substantial decrease: after having risen from £1,192,000 in 1913 to £2,784,000 in 1920, it fell to £2,776,000 in 1921 and to £2,572,000 in 1922. It is reassuring to observe that the greater part of this fall in expenditure since 1920 is not due to decrease in work but to reduction in cost. The report is a valuable document for all concerned in hospital management.

THE OTOLITH APPARATUS AND FŒTAL ORIENTATION.

As is well known, the internal ear is divisible into three parts, which subserve three separate and distinct functions: the cochlea serves for the perception of sound; the semicircular canals serve for the perception of movements of the head in space, or, more exactly, for the perception of acceleration of such movements; and the otolith apparatus for apprehension of the relative position of the head to the perpendicular, and also for the regulation of the muscle-tonus of the limbs, trunk, neck, and eyes. Our knowledge of the function of the otolith apparatus has recently been considerably advanced by the experiments of Magnus and de Kleijn, and it has been shown that, through reflex action from the otoliths, the various positions of the head in space influence the tonus of different groups of muscles of the trunk and limbs, and therefore the position of the body; the so-called "neck-reflexes," whereby alterations of position of the neck affect the tonus of the body-muscles, complicate these reactions, and it is probable that a whole series of similar reflexes exists which assist the animal in maintaining or in rapidly altering its posture. Dr. Ant. Precechtel, dozent in the Czechoslovak Aural Clinic of Prague, in a paper recently read before the Society of Czechoslovak Physicians, makes the suggestion, interesting alike to obstetricians and otologists, that these otolith reflexes play the principal part in regulating the position of the fœtus in utero, whereby some 97 per cent. of births occur as a head-first presentation. Dr. Precechtel argues that gravity will not explain this position, for the specific gravity of the fœtal head is found to be little if at all higher than that of the breech, while fœtuses experimentally floated in an artificial amniotic fluid were found to lower the pelvic pole. He criticises the so-called "accommodation" theories, by which the fœtus adapts itself to the shape of the uterus, or, by pressure of the active lower limbs against the unyielding pelvis, tends to turn the caudal pole upwards, and quotes the observation of Warnekros, who studied by skiagraphy the position of twins in a case of hydramnios and found that they kept a head-downward position in all postures of the mother. He supports his thesis by the observation that the otolith reflexes were obtainable in a large proportion of new-born infants, and by the significant fact that the vestibular branch of the eighth nerve myelinizes at the end of the fourth month, and considerably earlier than the cochlear branch or than the other sensory nerves. He has tried in vain to find corroboration by questioning the parents of congenital deaf-mutes as to abnormal presentations, but explains the lack of such abnormality by the fact that congenital defects of the vestibule are far rarer than those of the cochlea. It is an interesting speculation, but one very difficult of complete proof.

SYMBIOSIS AMONG ORCHIDS.

A remarkable instance of symbiosis between flowering plants and fungi is afforded by the association between orchids and their micorrhizal fungus, and was dealt with by Mr. Somerville Hastings in his inaugural address at the recent sessional opening of the Middlesex Hospital. This important work, necessarily abridged in our own columns,[1] may now be read at length in the current issue of the *Middlesex Hospital Journal.* With one doubtful exception every orchid so far examined is known to be infested with at least one fungus. The importance of the fungus to the host plant is shown by the fact that orchid seeds removed from the pod under aseptic conditions and sown on sterilised soil are unable to germinate, and, at most, swell up and turn green and then die. If, however, the seed is planted upon soil in which the parent plant was growing, and which consequently contains the fungus, germination results and a normal seedling is produced. With the entry of a single filament of the fungus into an orchid seed rapid cell divison ensues, and the filament gradually advances into the seed passing from cell to cell; it is, however, not permitted to penetrate too far, the seedling being apparently able to exclude its entry into the stem and root. The young root thus enters the soil free from fungus, and only becomes infected subsequently by the penetration into it from the soil of a new filament. Throughout the life of the orchid the fungus is restricted to the region of the root, only one case being known, that of the Bird's Nest Orchid (*Neottia*), in which the fungal hyphæ are allowed to penetrate all through the plant. The orchids thus infested with micorrhiza derive nourishment therefrom, being able to digest the coils of fungus within their cells. The fungus was first isolated and cultivated outside the plant by Noel Bernard in France, and named by him *Rhizoctonia* from its close resemblance to *Rhizoctonia violacea*, which produces a form of potato disease. The Japanese orchid (*Gastrodia*) produces tubers buried under ground and resembling those of the potato; every year the tubers give off offsets, just as a potato does, without, however, producing leaves or flowers; in succeeding years these offsets become progressively smaller until finally they become incapable of further growth. If, however, the tubers come in contact with fungus threads of the well-known "stump tuft" toad-stool (*Armellaria mellea*) full grown offsets are produced, which next year develop flowers and presumably seeds. The beneficial effect of the infection of this orchid by the stump tuft fungus is the more remarkable since this fungus is known all the world over as a destructive parasite which often settles in large masses upon tree stumps; it would appear that in attacking the thickened underground root of this orchid it becomes worsted in the struggle, and is made to yield to the orchid some of the food stolen from the neighbouring trees. These observations appear to give the clue to the origin of micorrhiza, since it is suggested that the higher plants may have developed an immunity against fungi originally parasitic upon their roots, and that they have obtained control over them and actually derive benefit from them. According to Bernard the entry of a single filament into an orchid seed excludes all others, even though it be an attenuated form incapable of effecting germination; for this reason he concluded that the first infection immunises the seed and prevents further infection, a process which he compared with vaccination. The significance of these discoveries with regard to orchid micorrhiza have been fully appreciated by commercial orchid growers, and in this country more particularly the growing of orchid seedlings under aseptic conditions has been brought to a high state of perfection by Ramsbottom and Charlesworth.

INTRAPERITONEAL INJECTION OF ANTITOXIN IN DIPHTHERIA.

We recently drew attention to a method of administration of antitoxin in diphtheria recommended by MM. Benhamou, Camatte, and Flogny,[1] of Algiers, which consisted in its injection by the intraspinal route. Dr. E. S. Platou,[2] of the Willard Parker Hospital and Research Laboratory, New York City Department of Health, now advocates the intraperitoneal route which is commonly employed for the injection of saline solution in infants. The new method was chosen owing to the absorptive power of the peritoneum which had been demonstrated by many observers. The technique employed was as follows: The patient was placed in the recumbent position with the arms and legs confined by a restraining jacket. The most suitable site is the linea alba just below the umbilicus. The skin is prepared with iodine and alcohol, and the area may be rendered anæsthetic by ethyl chloride. The antitoxin in doses of 10–14,000 units, with 8–10 c.cm. of saline, is introduced by gravity from an infusion bottle. The skin and subcutaneous tissues are picked up between the thumb and index finger and the needle is inserted obliquely, pointing upwards. After the antitoxin has penetrated the peritoneum it is allowed to flow into the peritoneal cavity. Dr. Platou has used the intraperitoneal method in a group of 12 severe cases, aged from 5 months to 14 years, in whom it was impossible to administer antitoxin intravenously. Ten recovered without complications, and two who were almost moribund on admission died, death being due in one case to laryngeal diphtheria and extensive broncho-pneumonia, and in the other to septic diphtheria and hæmorrhagic myocarditis. In both the peritoneum was free from any pathological condition. In none of the 12 cases was there any evidence of local discomfort from the injection. One patient presented slight urticaria on the seventh day, but none had any constitutional symptoms. Estimation of the comparative absorption of antitoxin by the intramuscular and intraperitoneal methods showed that within an hour of intraperitoneal injection the blood was appreciably antitoxic, and up to seven hours the absorption was about five times that found after intramuscular injection. The peak of absorption for the intraperitoneal method was about 36 hours, whereas for the intramuscular method it was somewhere between 48 and 72 hours. Dr. Platou regards the method as particularly applicable in advanced cases where suitable veins are lacking for intravenous administration, and in moderately advanced cases in which intravenous injection is not considered necessary or advisable, but where more rapid absorption is desired than can be obtained by the intramuscular method. Further observations are required to confirm the value of the intraperitoneal method, but in the meantime it is obviously desirable in view of the possibility of infection of the peritoneum that the method should not be employed as a routine in all cases of diphtheria, but should be reserved for the worst cases, especially those in which the intravenous route cannot be employed.

THE PERIODICAL EXAMINATION OF LIFE POLICY-HOLDERS.

AT a largely attended conference convened by the Federation of Medical and Allied Services at 12, Stratford-place, Oxford-street, London, W., on Oct. 24th, an interesting discussion took place on the value of the periodical medical examination of the apparently healthy as a factor in preventive medicine. Sir Malcolm Morris presided, and representatives, both lay and medical, of the following societies were present, together with prominent members of the organisation of the Federation :—

Eagle Star and British Dominions Insurance Company, Standard Life Assurance Company, Prudential Assurance Company, Legal and General Assurance Society, Wesleyan and General Assurance Society, Australian Mutual Provident Society, National Provident Institution, Royal Exchange Assurance, Refuge Assurance Company, Atlas Assurance Company, London and Manchester Assurance Company, Sun Life Assurance Company of Canada, Royal London, Mutual Insurance Society, Royal Liver Friendly Society, Commercial Union Assurance Company, Medical Sickness Annuity and Life Assurance Society, Coöperative Insurance Society, Hearts of Oak Assurance Company, Assurance Medical Society, Guardian Assurance Company, Public Health Advisory Committee, Clinical Research Association, Medical Sickness Annuity and Life Assurance Society, and the Sydenham District Medical Society.

In opening the conference the chairman pointed out that the Federation was a union of the various social activities concerned with health, and that it exists to promote the interests of the community as distinct from the interests of any professional section. The object of the conference was to serve the interests of the individual citizen—the policy-holder—while extending among the people the wise practice of seeking periodical examination or overhaul, in order that the early signs of departure from the standard of normal health might be detected. Already, he said, most sensible people visit their dentists regularly for examination of the teeth ; why not of other bodily systems ? Major L. G. S. Molloy, M.P., submitted a resolution stating : "That this conference approves the principle of periodical medical examination of life assurance policy-holders," remarking that such a principle, if carried out, would tend to the prevention of disease and would be a great advantage to the policy-holder if he did not have to pay for the examination. The medical profession would also benefit, but he feared that the insurance companies would be involved in expenses which they would not consider advantageous to themselves. Dr. Neville Spriggs, who seconded, was of opinion that periodical medical examinations would be for the benefit of all concerned. A long discussion followed as to the advantages or disadvantages to the public generally, and to the insurance companies, of such a principle as that advocated in the resolution, and a letter was read by Mr. N. Howard Mummery, Medical Director of the Federation, from Sir William Schooling, suggesting that the most beneficial and economical arrangement for both the original examinations for life assurance and for periodical re-examinations, would be the establishment of insurance medical institutes in the principal towns throughout the country. Finally, on the motion of Dr. Charles Buttar, seconded by Mr. Eric B. Nathan, the following resolution was unanimously carried : "That this conference approves the principle of voluntary periodical medical examination of citizens, and presses upon life assurance offices the desirability of the adoption of this course with the policy-holders."

THE CAMBRIDGESHIRE TUBERCULOSIS COLONY.

THE report on the Papworth Colony for 1922 is a beautifully illustrated work, printed by the members of this community. The outstanding event of 1922 was the formal opening of 31 new cottages, two hostels, and a nurses' home by Sir Alfred Mond who, in his address, referred to Papworth as the most wonderful institution of its kind in the world. He hoped that Papworth would be a model which would be copied in other parts of the country. Every page of this report is full of the author's vigorous optimism, and it is certainly to be hoped that the maker of Papworth, if not Papworth itself, will be used as a model and pattern by many imitators. Dr. P. C. Varrier-Jones, who further elaborated his ideas on village settlements on p. 912 of our issue of Oct. 20th, believes that all the progress made during 1922 has pointed to the soundness of the settlement idea. Of its success, if we are to judge by this report, there can be no doubt. It is more difficult to form a correct opinion of the reasons for this success. Dr. Varrier-Jones would have us believe that the principles on which he has worked are in themselves sound enough to warrant success. If this is so, and the problems of the Tuberculosis Settlement have been long enough studied for a mass production of Papworths to be attempted, such a procedure might be considered justifiable, provided adequate means are available. But if, as some suspect, the success of the first Papworth depends largely, and even mainly, on the personality of its founder, we should do well to delay creating replicas of Papworth till we can be assured of an adequate supply of replicas of its founder. To return to the first Papworth, it is worth noting that it is no longer in its infancy ; 1922 was the seventh year of its existence and the fifth since the transfer to Papworth Hall. Cases of surgical as well as pulmonary tuberculosis are admitted, and no patient is refused admission, however advanced the disease, if accommodation allows. The account given of the various industries shows that the presiding genius of Papworth is blessed with a business instinct. He has come to the conclusion that chicken farming is an occupation suitable only for those with marked resistance to the disease. The notion that poultry farming consists of dispensing grains of corn at odd hours to hens pouring out a steady stream of eggs is not quite correct. Boot-making and repairing is a trade the profits of which are mulcted by the heavy charge of employing a canvasser for the collection and distribution of repairs. But portmanteau and other leather work has yielded an annual turnover of nearly £4000 at Papworth, and this industry seems to be established on a firm basis. The total number of inhabitants in the village is now 152.

PREGNANCY COMPLICATED BY HEART DISEASE.

Prof. W. Frey, of Kiel, has published in *Zentralblatt für Gynäkologie* for Oct. 6th a paper on the prognosis of heart disease complicated by pregnancy. His review of the literature of this subject shows only too plainly that though it has been discussed for many generations, anything but unanimity has been reached. He suggests that the observations of various authorities are contradictory, partly because the material on which their observations were based was not similar, and therefore not comparable. He also suggests that the material available in an out-patient department is more suitable for an investigation of this problem than the inmates of a hospital, and he has, accordingly, conducted examinations of the cardio-vascular system of 1000 consecutive cases coming to his gynæcological out-patient department in 1917–18. In 49 cases definite valvular disease was found, but only one of these 49 women died during pregnancy as the result of heart disease. Only 32 of these women were traced two or four years later, when it was found that five had died. But it was very doubtful if any of these deaths were due to pregnancy. Prof. Frey has found that the expectation of life for men and women suffering from heart disease is practically the same. For women the average duration of compensation was 12 years, and for men it was 13. Necropsies told the same tale. There were very few cases in which the cause of the death of patients suffering from heart disease could be traced to pregnancy. Prof. Frey does not subscribe to the opinion that aortic disease is more serious than mitral disease in pregnant women. The prognosis depends, in his opinion, mainly on the vitality of the muscles of the ventricles. It does not so much matter whether the mitral or the aortic valve is involved as whether the disease is severe and acute or not. Among 29 cases of valvular disease examined post mortem there were as many as 24 in which signs of acute disease were found. This observation suggests that death from valvular disease of the heart is usually due to an acute exacerbation of the infectious process rather than to the purely mechanical factors associated with endocarditis. With regard to treatment, Prof. Frey classifies his cases according as pregnancy is associated with (1) recent inflammatory disease of the heart; (2) heart disease inadequately compensated, but not showing signs of active inflammation; and (3) compensation of the heart disease. The correct procedure in the third class is obvious; pregnancy need not be interrupted. But in the first class Prof. Frey advocates interrupting pregnancy whatever stage it has reached, whether the patient be a primipara or multipara, and even when there is satisfactory compensation. As a guide to the detection of active endocarditis he recommends taking the temperature in the rectum, and noting whether or not the patient is subject to tachycardia even at rest. The choice of procedure to be adopted in his second class of case is a difficult matter, but he is in favour of pursuing a conservative course as long as possible, in the hope that rest of body and mind and the administration of such drugs as digitalis may restore compensation and enable the patient to go to term.

THE MORISON LECTURES.

To a Scottish doctor must the credit be given of first instituting in this country special lectures on the diseases of the mind, and that at an early date when the conception of mental disease had barely advanced from the definition: "true madness, what is't, but to be nothing else but mad?" In 1823 Dr. (later Sir) Alexander Morison gave the first lecture on mental disease in Edinburgh. Five years previously he had studied under Esquirol in Paris, together with two or three eminent compatriots, for owing to the "auld alliance" Scotsmen even at that time were regarded in France with a certain friendliness. So impressed was Morison with Esquirol's teaching that on his return he made a strong endeavour to have a lectureship or professorship on this subject instituted in Edinburgh. One of his proposals was that the visiting physicians at Morningside Asylum—which had recently been built to supersede the barbarous city Bedlam—should deliver the lectures. This proposal was not adopted, but so keenly did he realise the importance of his subject that by a grant of private property to the Royal College of Physicians of Edinburgh he founded a lectureship in perpetuity, and for the next 30 years he or his son lectured annually. This year the centennial course of the Morison lectures was delivered in the Royal College of Physicians of Edinburgh on Oct. 15th, 16th, and 17th by Dr. Alexander Blackhall-Morison, his grandson. The subject of the course was, fittingly, a review of the progress of neurology, psychology, and psychiatry during the century since the foundation of the lectureship. In sketching the progress of neurology, Dr. Blackhall-Morison made a preliminary reference to the previous work of Whytt on reflex actions, to Haller's on organic action, and to the influence of Bichat as an interpretive anatomist, followed by the epoch-making experiments of Charles Bell and Magendie on the differing functions of the nerve-roots. The work of John Abercrombie, philosophical and medical, was referred to, and Gaskell's morphological investigations were especially dwelt upon. He then outlined the rise and progress of embryology, and the work of von Baer, Kölliker, His, Balfour and others was referred to. The results of the experimental work of Flourens, Marshall Hall, the Webers, Claude Bernard, Brown-Sequard, Schiff, and Ludwig were given, and the localisation of cerebral function by Fritsch, Hitzig, and Ferrier discussed, together with the clinical anticipation of such by Hughlings Jackson. The clinical discoveries of Todd, Duchenne, Charcot, Romberg and others of the German school were assessed, and the lecture closed with a consideration of the modern neural surgery of such pioneers as Horsley, Macewen, and Cushing. The second lecture dealt with psychology as a biology, and the growth of mental philosophy in the Scottish school was sketched. Dr. Blackhall-Morison considered the work done on mental faculties by Gall, Combe, and other phrenologists in the localisation of mental faculties, described the localisation of the special senses, and discussed the origin of language. Mind, he contended, was a living organism not a neural habit, and the importance of the persistence of the ego in general, and of the human ego in particular, was dwelt upon. The claims of the new psychology were examined and the place of judicious psycho-analysis in practice indicated. In the third lecture, the history of psychiatry from the end of the eighteenth century was outlined and the work of Haslam, Pinel, and Esquirol especially mentioned. In dealing with the ætiology of mental disorder, the lecturer estimated the influence of bacteriology and endocrinology, and special reference was made to the work of Mott.

The supreme importance of the care of the mind is becoming widely recognised among physicians, and the importance of early and adequate treatment of mental disorder is at last receiving some measure of consideration. In this connexion a paper by Dr. J. C. Porter Phillips[1] on the early treatment of mental disorder deserves attention. Asylum reform is going hand in hand with advancing knowledge, and special lectures on mental disease now form part of the curriculum in every medical school.

Sir Humphry Davy Rolleston has been appointed Physician-in-Ordinary to the King in the room of Sir James Reid, deceased, and Dr. Edward Farquhar Buzzard has been appointed Physician Extraordinary to His Majesty.

THE Nobel prize for medicine for 1922 has been divided between Prof. Archibald V. Hill, University College, London, and Dr. Otto Meyerhof, professor of physiology at Kiel University. Prof. Hill has, since 1910, been engaged on research on the formation of lactic acid in muscle during exercise, and in particular, its removal on recovery from fatigue, a continuation of the work done by Sir Walter Fletcher and Prof. F. G. Hopkins in 1908. As a mathematician and a physicist, Prof. Hill introduced into his investigations a totally different physical technique to that employed hitherto. Prof. Meyerhof, a close personal friend of his co-medallist, has pursued a similar course of research. The prize for 1923 has been divided between Prof. J. J. R. Macleod, F.R.S., and Dr. F. G. Banting for their work on insulin.

---

[1] THE LANCET, Oct. 20th, 1923.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XLIII.—TREATMENT OF BLEPHARITIS AND STYES.

Blepharitis, by which is understood a chronic marginal inflammation of the eyelid, includes several diverse conditions which, although similar in cardinal signs (redness and thickening of the lid margins) and symptoms (burning and itching of the lids, sensitiveness of the eyes to light, heat, and dust), differ in their ætiology, pathology, clinical cause, and prognosis. Certain rules applicable in the treatment of blepharitis in general can, however, be formulated. It is important to remember that obstinate cases of chronic blepharitis are often associated with errors of refraction, especially hypermetropia and astigmatism. This is probably because congestion of the lid margins and a consequent lowered resistance to infection result from constant straining of the eyes. These errors must be corrected, great care being taken to include especially small astigmatic errors. Glasses worn constantly not only eliminate strain, but protect the eyes from irritating influences, which may cause or at least aggravate the disease. Ill-health, insufficient nourishment, unhygienic conditions, and neglect of personal cleanliness often constitute important factors in keeping up a chronic blepharitis; obstinate cases are common in hospital clinics, and comparatively rare among private patients. The occurrence of obstinate blepharitis as the result of a distant focal infection has been reported. Blepharitis accompanied by lesions of a similar nature affecting the eyebrows, face, and scalp must be regarded from a dermatological standpoint, the lid condition being part of the general skin affection.

Inflammation of the lid margins necessarily involves the marginal part, at least, of the conjunctival sac, and is thus invariably accompanied by a conjunctivitis. But in many cases a conjunctivitis is the direct cause of the blepharitis, an eczematous condition of the skin being induced by constant lacrymation and discharge of muco-pus. This is especially common in cases of chronic eczematous or phlyctenular conjunctivitis in children, or in catarrhal conjunctivitis caused by the Morax-Axenfeld diplobacillus. Treatment must here be directed towards removal of the conjunctival disease and of conditions likely to cause it—e.g., stenosis of the lacrymal passages, eversion of the punctum, &c.

Massage of the lid margins is often a useful adjunct to treatment, especially in chronic cases, ensuring the emptying of the infected secretions of the follicles and glands. It is carried out by means of a round-ended glass rod, which is gently rubbed along the inner conjunctival surface of the edge of the lid, support being given to the latter by the thumb, held against the outer skin surface. This is apt to be a painful proceeding, and must be done with gentleness.

A *bacteriological examination* of secretions from the eyelids and conjunctiva by direct film and culture, affords valuable information in many cases. For example, presence of the Morax-Axenfeld diplobacillus indicates the use of zinc solution or ointment.

The *onset* of blepharitis usually occurs in childhood, when early and persistent treatment is of the highest importance. In untreated cases the lid margins may become permanently altered, owing to destruction of some or all of the eyelashes and the formation of scar-tissue, making a complete cure impossible. Eyelashes which escape destruction may become stunted and distorted and rub against the cornea, causing intense pain and photophobia, and giving rise to ulceration of the cornea and interference with vision. The lid margins may become thickened and rounded and ectropion may result.

Differential diagnosis from uncomplicated conjunctivitis in cases with dried crusts or scales in the neighbourhood of the eyelashes is made after removal of the crusts, the lid margins being normal in the last-named condition and always red, often thickened and sometimes ulcerated, in the presence of blepharitis.

Local Treatment of the Lid Margins.

In general the essential measures are: (1) A careful cleansing with a detergent solution to remove all secretion and crusts, with removal of loose lashes, followed by (2) the application of antiseptic ointments with gentle friction. Sod. bicarb. in warm 3 per cent. solution is the most generally serviceable cleansing solution. It has little or no germicidal power, but is non-irritating and softens the hard crusts of dried secretion. Ointments should be used twice daily; in the morning the greater part is wiped off again, but overnight a thick layer should remain on the lid margin. Antiseptic ointments are useful, both because of their antiseptic properties and of the protection afforded to the inflamed part by the greasy excipient. It is useless to apply ointment until all crusts have been removed. Antiseptics with highly irritating properties must never be prescribed, as they tend merely to aggravate the trouble instead of effecting a cure. Yellow oxide of mercury, so widely used in ointment form, is a striking and common example of this mistake; owing to its irritating action it often fails to effect a cure. Ammoniated mercury (1 per cent. in vaseline) is preferable and is one of the most generally useful drugs.

(3) Silver salts in solution are of sovereign use, especially in ulcerative blepharitis. Silver nitrate, in 1 per cent. to 2 per cent. solution, or some of the proteid compounds of silver (e.g., protargol 10 per cent., argyrol 20 per cent.) may be employed. Most forms of the disease are extremely obstinate, and the length of time during which treatment must be continued, as well as the chances of a permanent cure, are usually inversely proportional to the duration of the disease. In the treatment of milder cases vaccines are rarely used, but are undoubtedly beneficial in certain obstinate cases, especially those of staphylococcal origin. In my experience those cases which benefit by this treatment require its continuation. Directly the injections are discontinued the lid inflammation exacerbates only to improve under a fresh course of injections.

Common Clinical Varieties.

The common clinical varieties of blepharitis, in all of which correction of refractive errors is a necessary preliminary to any form of treatment, are:—

(1) *Simple chronic hyperæmia* of the lid margins without appreciable thickening, usually affecting both eyes and associated with sensitiveness of the eyes to dust, glare, tobacco-smoke, and strain. Treatment: Appropriate glasses must be prescribed, slightly tinted if necessary.

(2) *Squamous blepharitis* usually affects both eyes. The lid margins are hyperæmic, and slightly but evenly thickened, and the skin surrounding the eyelashes is covered with fine whitish scales consisting of dried sebaceous secretion. There is no ulceration. The condition is a seborrhœic one, and is often extremely resistant to treatment. Treatment: Careful removal of the scales and loose lashes, twice daily, with sod. bicarb. solution. Massage of the eyelids, with expression of the contents of the meibomian glands, and subsequent application of an ointment. In the diplobacillary cases the following is most effective: Ichthyol ammoniate, 0·2 part; zinc oxide, 5 parts; vaseline, 15 parts; and the conjunctival sac should be irrigated with a solution of zinc sulphate (½ to 1 per cent.). For the staphylococcal cases ammoniated mercury ointment is the most useful; other ointments (e.g., salicylic acid, 1 per cent.; resorcin, 1 per cent.; ichthyol, 1 per cent., and simple boric ointment) may be tried. Squamous blepharitis does not give rise to deformity of the lid margin.

(3) *Ulcerative blepharitis* may affect one or both eyes. The lid margin is red and unevenly thickened. Hard crusts of dried secretion surmount the lumpy

thickenings and cling tenaciously to the eyelashes; on their removal ulcerated surfaces, which bleed readily, are exposed, and small abscesses may also be present; usually *Staphylococcus aureus* may be found. This, the severest form of blepharitis, is most common in children, and is a frequent sequela of measles. If allowed to persist, destruction and scar formation result. Treatment consists of thorough removal of all crusts twice daily with sod. bicarb. solution, and of loose eyelashes with epilation forceps; application of 2 per cent. silver nitrate solution once a day to the ulcerated surfaces with a cotton-wool wrapped probe, or in less severe cases repeated friction of the edges of the lids with a camel's-hair brush dipped in 10 per cent. protargol solution; subsequent application, twice a day, of ammoniated mercury ointment. Attention must be paid to the general health.

(4) *Eczematous blepharitis*, in conjunction with and secondary to a conjunctivitis. The skin of the lid margins is reddened and excoriated. Treatment: In addition to that appropriate to the conjunctival condition, the edges of the lids should be kept greased with ointment as a protection against conjunctival discharges. Boric ointment, ammoniated mercury, or ichthyol and zinc in the diplobacillary cases, may be used.

(5) In a true *sycosis* of the eyelashes the lid margins are swollen, and show numerous small abscesses in the hair follicles, an eyelash appearing in the centre of each point of pus. The eyebrows are usually affected as well. This condition is very intractable, and must be treated by daily epilation of the lashes, evacuation of the abscesses, and the application of mercury or other ointments.

Styes.

Styes are of two kinds, external (the common variety) and internal. The former is an acute pyogenic infection of an eyelash and its sebaceous glands, the latter a similar infection of a meibomian gland. Both kinds are accompanied by œdema, often intense, of the eyelids. The external stye, which appears as a painful swelling on the anterior border of the lid, may sometimes be aborted by extraction of the eyelash and application of a pointed match dipped in pure carbolic, followed by frequent bathing with very hot boric lotion. This is best done with a sponge stick made by tying a piece of lint round the handle of a wooden spoon. "Blind" styes should be treated in this way. If the stye points it should be opened under local anæsthesia, produced by subcutaneous injection of novocaine solution round the base of (not into) the swollen area and fomentations applied. Recurring styes often disappear when errors of refraction are corrected. Sometimes they indicate lowered resistance to staphylococcal infection, when vaccine treatment may prove beneficial. The lids should be cleansed nightly for several weeks with sod. bicarb. solution, followed by application of ammoniated mercury ointment, in order to check the formation of fresh styes.

Internal styes are comparatively rare—they point on the conjunctival surface, and must be opened there, and fomentations and hot bathings applied. Occasionally the acute stage passes off without discharge of pus, a chronic meibomian cyst resulting, which can be got rid of in the usual way by incision from the conjunctival surface, and scraping with a sharp spoon.

POINTS FOR CONSIDERATION IN MOTOR-CAR SELECTION.

(BY OUR MEDICAL MOTORING CORRESPONDENT.)

AT the International Motor Exhibition now being held (Nov. 2nd to 10th) by the Society of Motor Manufacturers and Traders at Olympia, Kensington, some 522 stands have been allocated to exhibitors and about 140 makes of cars are on view. The would-be purchaser will have plenty from which to choose. To extract the grain from the chaff will be the difficulty.

As user of cars for professional purposes the medical man's chief concern is reliability combined with simplicity. Most of us do not buy cars to replace them 12 months hence. We usually purchase "for keeps" and do not propose considering a new car for anyway three or four years. Thus the car's family history becomes a deciding factor. Some of the latest manufacturers may not weather what, with the present severe competition, may prove a stormy season. This may mean difficulty in procuring replacements if the makers are not in existence next year. Thus the advantage in selecting old-established firms. Another guiding point is the second-hand value of the car in view; a high second-hand value is a good test of a car's quality.

The coach-work is, of course, a matter for individual choice. For protection from wet and cold and quick conversion into an open car, the all-weather body will appeal to many. Instead of glass windows the type with curtains fitted to and opening with the doors, as originally brought out by the Standard Motor Company, is now justly popular and can be supplied with most cars.

The Engine and Transmission Design.

The important point is the engine and transmission design. What constructional factors should influence selection? For the larger cars four cylinders are almost universal and are certainly desirable; more is a luxury. For the doctor's purpose 12 h.p. is ample, even in hilly districts. It has, too, the advantage of economy in tyres and a moderate tax. The question of the type of engine valve is debatable. The overhead, operated by push rods and rockers, or an overhead cam-shaft has many advocates. It is rather more complicated and means more trouble when dismantling for decarbonisation is needed. With correct feeders the occasional needed adjustment is simple enough, yet many owner-drivers ignore this need and suffer accordingly. Side-by-side valves are easier to get at and have the advantage of simplicity. They probably do not conduce to as much power in a high-speed engine. Their retention in such excellent cars as the Fiat and Unic is an argument in their favour. The taxi-driver usually knows what he talks about. Like ourselves, he is out for simplicity and reliability. He says he gets it on the side-by-side valved Unics and Fiats.

Personally, I do not mind giving my mount a little attention, perhaps that accounts for my partiality for the overhead kind. With a good maker whatever form is fitted as standard can, I think, be accepted with confidence. With modern practice, the old axiom, "For each throw a crankshaft bearing" is obsolete. With three bearings as now designed, whip does not occur. Even two bearings on small 4-cylinder engines are found to be quite satisfactory. Connecting rods are now often lined with anti-friction metal direct. Many engines run for 40,000 miles before the big ends need attention; when they do, then the advantage of removable lined brass or gun-metal bearings is discovered. Their absence means more trouble and expense. The lighter high-speed small engines usually develop a knock under considerably less than the distance just mentioned, so anyway for these the brass-lined bearings are preferable. War aeroplane experience introduced the aluminium alloy pistons. They lighten the reciprocating parts and thus ensure smooth running. Use on car engines has certainly proved the value of this innovation. On the larger engines the provision of four piston rings is an advantage. It means better compression, and what is as important, less passage of oil into the combustion chamber. If much gets into that compartment preignition is bound to occur, and that means the trouble of decarbonisation.

A slipping as well as a fierce clutch is a misery. Either the cone or single plate lined with Ferodo or leather is satisfactory. In addition this type is simple to adjust or can be. I say this feelingly as on some cars clutches are introduced in such a way that their removal to re-line may cost as many sovereigns as the shillings expended on the lining. Ease is also essential to increase the tension of the clutch spring or springs. The arrangement on the Overland in this respect struck me as ideal. A good many clutches are covered in; it is well to protect them thus. It is, however, abominable to try and take out split pins and increase the tension of a clutch-spring by tightening nuts, through a trap-door, say, three by two inches, to get at which, in addition, calls for acrobatic contortions. Many gear-boxes are bolted directly on to the engine. The advantage of this unit construction is perfect alignment, and the elimination of a universal joint between the gear-box and engine. Still on many this causes the complications I have just mentioned—difficulty in dismembering the clutch. Everything in this world, including the automobile, is a compromise.

Forward Gears.—Fabric Universal Joints.

The matter of three or four forward gears is unimportant, except that four means an increase in production cost, and therefore purchase price. A geared-up fourth speed permits of faster running on the level, otherwise there is little advantage. Regarding the position of the change-speed lever, use soon makes either the side or the central seem preferable; the former means more room for the front passenger, the latter permits of a door and thus a means of exit on the driver's right.

Fabric universal joints for the transmission shaft, as used on the Standard and Waverley cars, are becoming popular. They have the advantage of neither needing lubrication nor of becoming noisy. For the final drive spiral gear has much in its favour, though on some cars the worm is still used. A few cars, such as the small Talbot and the Rhode, are constructed without a differential. It does not seem to cause any difficulty in driving or turning, though it is suggested that the skidding, which must result, may cause excessive tyre wear. During the war, in France, there was at one time a shortage of spider pinions for the differential of the Rover and Sunbeam cars used at the front. They were urgently required, so the differential was temporarily done away wth. The result, as might be expected, in cars of that size (they were ambulances) was not satisfactory. Most modern carburetters give satisfaction. The Zenith, S U, Solex, and Claudel certainly deserve mention, especially the latest type of the first-named. The points to make sure of are accessibility to the strainer and jet or jets. I have seen a car, on which the shield had to be dropped to get under the carburetter to remove the jet, or if this was not done, the exhaust manifold had to be disconnected to get the carburetter off. For simplicity the gravity petrol tank under the bonnet is impossible to beat. For convenience of space a pressure-worked rear tank is often employed. It is efficient, but I must confess to a preference, as already mentioned, for the gravity one under the bonnet. The Autovac, as used on the "tanks," is reliable, provided the owner does not neglect to keep it clean, otherwise trouble not only may but is bound to occur. For ignition the results are equal with either coil or magneto. The former, now that generators are fitted and keep the accumulators fully charged, is quite good. The objection is that it is not much use charging accumulators if the acid level is not maintained. Those who neglect to do so rather unjustly condemn the coil. I believe this is the reason the Talbot-Darracq have changed back to the magneto. The Wolseley favour the coil. A self-starter is now a sine qua non. It should be fitted so that if the pinion jams it can be removed without too many awkward postures.

On the cheaper cars thermo-syphon cooling is popular. Provided the water pipes are of sufficient size, it is satisfactory, but I must say I prefer a pump-propelled circulation, and one too with (on the larger cars anyway) a thermostat attachment, which maintains a constant water temperature. As to air-cooled engines, some are satisfactory, though my feelings are in favour of the water-cooled. The engine lubrication is now excellent on nearly all cars; it is by pump with an indicator on the dash to show that the oil is circulating, and a rod to show the depth in the sump. For the chassis I should insist on lubricators fed by a grease gun; it saves much cleansing of hands and gloves.

Brakes, Springs, and Tyres.

Many brakes now both operate on the rear axle drums. This method seems preferable to having one on the cardan shaft and the other on the rear wheels. The transmission shaft brake, though efficient, is not healthy for the life of that part. Front wheel brakes, when adjusted and kept in adjustment, with all the moving parts lubricated, are ideal, as was pointed out in THE LANCET of Nov. 14th, 1908, when the Allen-Liversidge original type was tested. The Buick are now fitting them as standard, but as yet few of the well-known British manufacturers have done so, though some fit them to order. For ordinary use I question their need, anyway they are not a necessity.

The question of comfort in driving depends on the springing of the cars; cantilever, three-quarter, and half elliptic all have their advocates. I believe that the first two give the best results, provided that the springs are kept lubricated. Any type that as a result of wet and mud has become rusted into a solid piece is inefficient. Some protective covering, such as the Duco leaf-spring gaiter, does enable a spring to function, by allowing each component leaf to move on its neighbour and thus absorb road shocks before they reach the car. The Gabriel snubber is a satisfactory device to eliminate rebounding. It is fitted as a standard on the Morris-Oxford car.

What looks like a promise of an increase of comfort is shown by Messrs. Michelin and Dunlop in the shape of larger tyres, which are constructed for use with a very low pressure, 16 to 20 lb. The cushion effect is said to be marvellous and with rebound snubbers may do away with all need for shock absorbers. The question to be solved is whether, by increase of road friction, they will lead to a larger petrol consumption. The point of retention in position has been met by the Dunlop firm, by an alteration in the method of attachment. They are, of course, still somewhat in the experimental stage.

Some Suitable Cars.

Among cars suitable for inspection can be named, among the light two-seaters at £160 to about £200, the Austin, Citroen, Gwyne 8 h.p., Hands, Humber, Morris-Cowley, Rhode, Standard, and Wolseley. For larger cars at from £400 to £500, the Angus-Sanderson, Armstrong-Siddeley (£360), Austin (£450), Calcott, Clement-Talbot, Crossley (a wonderful 15 h.p. at £420), Cubitt, which is a powerful mount at £340, Talbot-Darracq, De Dion, Fiat (now reduced to £420), Humber, Morris-Oxford, Renault, Standard, and Swift, while those who do not mind going to a little higher price should certainly look at the Sunbeams, Rovers, and larger-powered Wolseley; the 14 h.p. of the latter make seems very good value, as well as the Rover. For a really good American, which is now built in England, the Overland in the neighbourhood of £300 is a good proposition. Among other American cars the Dodge and Durant are worthy of attention, as well as the Maxwell at £330, the Buick at £375, and the six-cylinder Studebaker, made in Canada, at £385.

PRIVATE WARDS AND BEDS IN THE LONDON HOSPITALS.

IN view of the professional and public interest aroused by recent announcements of the institution of paying beds in some of the larger metropolitan hospitals, and of the difficulty sometimes experienced by practitioners in actually placing an individual patient in such beds, we have endeavoured to ascertain from the secretaries of various hospitals under what conditions paying patients are admitted. The answers received are summarised in the table given below, and show that at Guy's, St. Thomas's, and King's College Hospitals certain arrangements are made in this direction; as also at the Royal Northern, the Hampstead General, the three hospitals controlled by the Seamen's Society, the Bolingbroke, the Willesden General, and two or three others.

There are no private wards for paying patients of moderate means in the following hospitals: St. Bartholomew's Hospital, London Hospital, Middlesex Hospital, St. George's Hospital, St. Mary's Hospital, Royal Free Hospital, University College Hospital, Prince of Wales's General Hospital, Hôpital et Dispensaire Français. The West London Hospital and the Westminster Hospital are now making arrangements to provide accommodation for paying patients, and the Miller General Hospital hopes to do so in the new wing next spring. The Italian Hospital has the matter now under consideration, and at the Royal Free Hospital it is hoped in the future to provide such accommodation on an adjoining site.

Interesting Points.

Many interesting questions arise in connexion with private beds in general hospitals, especially in view of the contributions towards maintenance now asked from patients in general wards of many hospitals if they are judged able to afford them. Separate payment to members of the staff appears to be a fairly general feature, and concessions in the way of more visitors and extra or daintier food are allowed in certain hospitals. Of the undergraduate teaching hospitals Guy's, St. Thomas's, and King's College Hospital have private beds more or less attached to the hospital, and the Royal Free and Westminster hospitals hope to provide such beds in the future. At Guy's and St. Thomas's the private ward or block is a separate entity, with a salaried medical officer whose services are available free to the patients. Students from the medical school are excluded from these wards, and the food and cooking are on a different plan from that of the hospital. At King's College Hospital reference to the table given below will show that an attempt at grading is made, which may at

Name of hospital.	Private wards (p.w.).	Cubicles.	Private rooms (p.r.).	Total beds.	Fees in guineas per week.	Extra fees for staff, if any.	Visitors.	Remarks.
Guy's Hospital.	1	24		24	5	Salaried R.M.O. gives services free of charge. If necessary member of hon. staff is consulted and fee for treatment or operation arranged privately between him and patient. No proportion of maintenance fee is paid to staff.	Daily 9–12 and 2–5 instead of twice weekly.	Students in medical school are not admitted to this ward for teaching purposes. Separate kitchen and kitchen staff.
St. Thomas's Hospital (St. Thomas's Home).		40		40	5	R.M.O. attends free. Consultation paid for by patient.	Daily 3–5.	Food is better in home than in general hospital.
King's College Hospital.	3		13	44	p.r. 6 to 8, p.w. 4½ to 5.	Payment to be made to members of staff is arranged by house governor on admission of patient.	Daily instead of twice weekly.	Slight difference in evening meal provided for private patients. Patients in p.r. are not available for purposes of demonstration to students. In case of patients in p.w. the member of staff attending them may be accompanied by his students.
Royal Northern Hospital.	2	46	18	66	p.r. 4 to 6, p.w. 2 to 4.	Patients in p.r. pay moderate fees to consultants, who must be on staff of recognised hospital, but not necessarily the Royal Northern.	Sundays 1.30 to 3. p.r. 5–6 daily. p.w. 5–6 twice weekly.	Special wards primarily intended for residents in North London. Two beds for paying patients available at the Reckitt Convalescent Home, Clacton-on-Sea.
Hampstead General and N.W. London.	3		6	20	p.r. 5, p.w. 3.	Fees to staff by arrangement.		Patients in p.r. have evening meal, in place of cocoa, milk, or bread-and-butter.
Dreadnought Hospital.	4			8	From 3.	Any amount paid additional to cost of maintenance, approx. 3 gns.		Practically no difference in food served to paying and non-paying patients, but table-napkins, tray-cloths, bed-tables, &c., are afforded to the former.
Albert Dock Hospital.	2			3	,,	,, ,, ,,		,, ,, ,,
Hospital for Tropical Diseases, Endsleigh Gardens.				30	From 5.	Patients who can afford it pay staff a weekly fee.		,, ,, ,,
Willesden General Hospital.				15	From 3½ to 6.	By arrangement with doctor attending, who need not be attached to hospital staff.		
Bolingbroke Hospital (Wandsworth).	2		4	12	p.r. 5 to 6, p.w. 4.	R.M.O. attends free, but a fee is payable to members of hon. staff.	Daily.	Patients are given special consideration in the matter of food; late dinner is provided.
Queen Mary's Hospital for the East End.			4	4	5		No fixed times.	Food identical with that served in rest of hospital.
Hospital of St. John and Elizabeth.			10	10	From 8.	Paid direct to staff by patients.		Patients attended by their own medical men.
St. Andrew's Hospital (Dollis Hill).			9	45	p.r. 8, p.w. 2½ to 4.	Patients in p.r. arrange fees with med. staff. Patients in wards pay reduced fee to med. staff.		No patient is received except on the recommendation of his own doctor. Patients unable to pay 2½ gns. are received free as far as is possible.

ome time cause discontent either among the patients r in the medical school. Patients who pay 8 guineas week in private rooms (special treatment is extra, ıch as massage 10*s*. an hour, X ray treatment from guineas a week, barium meal 5 guineas) are immune om the attendance of students. Those in private ards may apparently give or refuse their consent r the member of the staff attending them to bring is students to their beds on a round. The wording f the rule on this point suggests that in any case ıese patients will not be available for examination y students except in the presence of their chief, but nly for demonstration purposes with their consent. nasmuch as the wards opened for private patients t King's College Hospital appear to be those which ere previously closed for lack of funds, no present ardship for students exists. However, admission of he principle that patients, who already pay maintenance fees, may by paying an additional guinea or two er week acquire the right to refuse examination by tudents has its dangers.

Another interesting point is that of telephonic ıquiries about patients, which are not answered at King's, nor, indeed, at most large hospitals. A atient who pays a fee of 8 guineas a week, which is ot in excess of that asked in many a nursing home, ıay dislike being deprived of this facility on his iends' behalf. Against this, however, is the feeling of curity which the nervous patient in a large hospital ell staffed by resident house surgeons and physicians ıust feel, compared with the anxiety often experinced in a nursing home without a resident doctor. Ve believe that, on the whole, patients of moderate ıeans will be glad to avail themselves of the opporunity to go to a hospital when they are ill, and that heir advent will do much to raise the standard of omfort in the general wards by calling attention to he therapeutic value of properly served, hot food, of ermission to smoke, and of other amenities which ıay increase slightly the cost of administration, but ill give quite disproportionate amount of satisfacion to patients.

SCOTLAND.

(From our own Correspondents.)

The Insurance Position in Glasgow.

About 250 medical men, including representatives rom Lanarkshire, Ayrshire, and Stirlingshire, attended meeting held on Oct. 23rd in Glasgow. The report f the local Medical and Panel Committee was conidered, and Dr. H. G. Dain, Birmingham, outlined he history of the dispute and its present position. A hort statement was then made by Dr. J. R. Drever, he Scottish secretary of the B.M.A. The meeting ınanimously decided: (1) To support the Insurance Acts Committee; (2) to put into force immediately the ollective bargaining scheme. By the 28th the resignaions of 86 per cent. of panel practitioners were in the ıands of Dr. J. G. McCutcheon, the secretary.

Anderson College of Medicine: Opening Address.

At the opening of the winter session of the Anderson 'ollege of Medicine a lecture was delivered by Sir Ronald Ross. The lecturer took as his subject the Management of Medical Research. He briefly recapituated the advances made during the past 20 years n the field with which his name is associated s pioneer; advances which rendered possible, by fficient hygiene, the construction of the Panama 'anal, and the successful campaign against malaria onducted by Malcolm Watson in the Federated Malay States. These triumphs were achieved by the iecing together of much painstaking investigation; nd that not only, as the lecturer insisted, in medicine lone, but also in the sister sciences of physics, hemistry, and zoology. Sir Ronald Ross went on to ay that the value of combined investigation of this ıature was for centuries unrecognised. The earlier undamental discoveries in the history of the world were made by what he called "private enthusiasts"—men whose living was often precarious, and not infrequently attained by the practice of a popular but remunerative offshoot from their life's work. Thus Kepler: "Mother astronomy would surely starve but for the earnings of her daughter astrology." Subsidised research began with the observatory of Tycho Brahe, which, although no new principle emanated from its walls, yet supplied the data from which the wider perspective of Kepler and Newton revolutionised the science. Research as a profession had come tardily and incompletely into its own during last century, with the founding of the Pasteur and Jenner Institutes, and at the present time not only medicine, but also both pure and industrial science supported skilled investigators over all the world. In this country the Government had accepted the principle with the founding of the Medical Research Council. Regarding the conduct of purely medical research, Sir Ronald Ross distinguished two schools of thought. One, "the Bulls," would have all available money spent upon the equipment and maintenance of bodies of skilled investigators, in the hope that the mere bulk of work done would yield here and there a fact of vital importance, although much of the work might be erroneous or incomplete. The other, "the Bears," replied that while it was easy to carry out the first plan, the genius behind an epoch-making discovery could not be bought. In support of the first school the lecturer pointed out that science required for its advance both the collection of facts and inductions based upon them. Thus Darwin consolidated the observations of Buffon and Linnæus in the "Theory of Evolution"; modern bacteriology presented in a new light age-old observations upon the characters and symptoms of human disease. Again, the elucidation of a given problem required observations by many workers, each skilled in his particular branch. Waste was inevitable, but justified by the end. On the other hand, many of the great discoveries in the history of medicine had been made by men who were neither subsidised nor equipped with an adequate laboratory —Harvey, Jenner, and Lister among them. Their laboratories, said the lecturer, were in their brains. Unfortunately the reputation of having a laboratory leaning was even to-day sometimes injurious to practice; so that the doctor was tempted, even on occasion obliged, to shun laboratory investigation. The private enthusiast could not be discovered until he had done his work, but Sir Ronald Ross thought that the least the State could do for him after discovery was to repay his expenses, and the most, to enable him to continue at work. The apathy of the great majority of human beings to the subsidy of medical research was amazing to the lecturer; their money was too often applied to futile projects, for they ignored the personal menace of disease. The lecturer concluded by exhorting his hearers first to practise the cure or prevention of sickness, and, if possible, in their leisure to try to solve some problem in science.

Aberdeen Medico-Chirurgical Society.

A meeting of the Society was held on Oct. 25th, when the President, Dr. Alexander Ogston, delivered his presidential address on Observations on Some Modern Methods of Anæsthesia. Dr. Ogston first gave a brief survey of the methods of anæsthesia in common use in Aberdeen within his own experience, pointing out that up to about 1917 the method in practically universal use was the administration of chloroform, or in rare cases ether given in a cone-shaped towel. As long ago as the early eighties of last century Dr. Blaikie Smith, however, had devised and used with a certain amount of success a special inhaler of leather and metal with flannel padding for the administration of open ether. About 1917 open ether came into more common use, having been brought to the notice of the anæsthetists by Sir Henry Gray after a visit to America. Dr. Ogston then discussed this method, indicating its difficulties, and describing the various methods in use and the types of apparatus, including his own special mask which prevented the diffusion of the ether vapour. The intra-tracheal and rectal methods were specially referred to. Nitrous oxide and oxygen as an anæsthetic was then discussed and apparatus shown; modern improvements were indicated, and the use of this anæsthetic with the addition of ether or of chloroform and ether described.

Nobel Prize Awarded to Prof. J. J. R. Macleod.

Dr. J. J. R. Macleod, professor of physiology in the University of Toronto, has been awarded the Nobel prize for medicine for 1923, along with Dr. Banting. He is a distinguished graduate of Aberdeen University, and a son of the Rev. Robert Macleod, Senior Minister of John Knox U.F. Church, Aberdeen. Prof. Macleod was educated at the Aberdeen Grammar School and at Aberdeen University, where he graduated M.B., Ch.B., with honours in 1898. Four years later he obtained the degree of D.P.H. at Cambridge University. After studying at Leipzig and Berlin, he became demonstrator of physiology at the London Hospital, later lecturer in chemical physiology and pathology in the Sir Andrew Clark Institute, London. During the following year he was appointed professor of physiology at the Western Reserve University, Cleveland, Ohio. In 1918 he took up his present post. In 1913 he published his paper on diabetes. The research work, which resulted in the discovery of insulin, was carried out in the Toronto laboratories under his supervision.

IRELAND.

(From our own Correspondent.)

Dublin University Biological Association.

At the opening meeting of the Dublin University Biological Association, held on Oct. 27th in Trinity College, Dr. George E. Nesbitt, President, gave an address on Modern Developments of Medicine. Having touched on various other topics, he devoted most of his time to the study of kidney disease and to the modern treatment of diabetes. He gave the results of his experience with insulin, and expressed the opinion that 75 per cent. of cases of diabetes could be controlled by dietetic measures without resort to insulin. Prof. Hugh MacLean, of London, was the principal speaker. He discussed the relations that should exist between bedside and clinical laboratory work, and defended the teaching of laboratory methods to medical students. He agreed with Dr. Nesbitt that much might be accomplished by dietetic measures for the treatment of diabetes, but his experience was that invariably the case at some time went out of control, even when the dieting was very careful. The patient that kept to the diet laid down might get on all right for a year or two or more, and in the end show sugar. He believed that modern dietetic work had done quite a lot to lengthen the life of a diabetic patient, say, from two or three years to six or seven years, but that was all that it had done. That was his experience in the hundreds of cases that he had treated.

Dr. Henry F. Moore, in seconding a vote of thanks, announced that the price of insulin was about to be reduced by half. Other speakers were Sir Thomas Myles and Prof. W. Caldwell.

The Local Government Board and Private Practice.

The Council of the Irish Medical Association had under its consideration last week the report of an inspector of the Local Government Department dealing with complaints made against the medical officer of the Birr Hospital. The complaints were found to be groundless, and the patient at any rate had no claim to attendance from the medical officer in question. The report, however, went on to say:—

> “The charges are obviously not of a serious nature, but they involve principles which must be clearly defined . . . Obviously a doctor, and more especially a medical officer in receipt of salary from the rates, when called upon to attend an accident case, is not justified in assuming from the statements of a lay person that his immediate attendance is unnecessary, and that the case can wait for the presence of another doctor whose particular duty it is to attend to it. . . .”

A copy of this report was forwarded to the local authority under whom the medical officer serves. The Council of the Irish Medical Association has registered a protest against the action of the department by passing the following resolution:—

> That the Council had under consideration the report of the Local Government Department Inspector in regard to charges brought against Dr. Fleury, of Birr, in which report a certain degree of blame is attributed to Dr. Fleury. The Council begs leave to point out that Dr. Fleury's services, for which he is paid by a public authority, are limited to attendance on patients admitted to the hospital of which he is medical officer. Dr. Fleury is under no obligation to attend accident or other cases outside the hospital, and such attendance would be merely an incident of private practice. The Council, further, is unable to concur in the assumption of the inspector that “a doctor and more especially a medical officer in receipt of salary from the rates,” is liable to censure or control by the department in regard to the conduct of his private practice.

A copy of the resolution was ordered to be sent to the press, as well as to the Ministry of Local Government.

Oct. 30th.

UNITED STATES OF AMERICA.

(From an Occasional Correspondent.)

An Employment Agency for Consumptives.

It is now several years since the United Hebrew Charities and some other Jewish organisations in New York launched the Altro shop—an industry in which only the tuberculous were to be employed. Both from the financial and the therapeutic points of view this shop has proved a very noteworthy success. The patients or workers are under constant medical supervision and are not permitted to do more work than the doctor prescribes. Care is taken that their wages shall never be insufficient to provide for themselves and their families; at the same time an ingenious arrangement of rewards prevents any inducement to practise “soldiering.” The shop is situated in the Bronx district and the workers therefore travel out to work and home from work in the opposite direction to the flow of heavy traffic during the rush hours. So impressed have been the officials of the National Tuberculosis Association with the success of this small enterprise, that they have now designated a member of their staff to make a special survey of the industry. At the same time there comes from the director of the New York Tuberculosis Association, Mr. J. Byron Deacon, a very important announcement concerning an experimental labour bureau which they are about to furnish for the benefit of tuberculous citizens of New York. The purposes of this bureau were announced to a recent meeting of the New York City Conference of Charities and Correction as follows:—

1. To study industries and analyse the jobs therein, in order to discover suitable occupations for persons with tuberculosis in quiescent or arrested stages.
2. To give vocational counsel to and find employment for persons in arrested or quiescent stages of tuberculosis, making the initial contact in the sanatoria where possible, coördinating the work with the medical and social services of tuberculosis clinics, sanatoria, and family welfare agencies.
3. To precede placement with thorough medical examination and to follow placement with intensive medical and social service supervision.
4. To broaden the opportunities for suitable employment for the tuberculous by a campaign of education of employers.
5. To develop, in connexion with the existing training schools for the handicapped, and with selected industrial establishments, facilities for trade training for individuals who cannot be placed directly at suitable remunerative work.
6. To study and interpret the experience derived from the aforementioned activities for the benefit of tuberculosis agencies generally.

The bureau is known officially as that of vocational service for the tuberculous. Its staff consists of an executive, a medical consultant, two placement secretaries, a medical social worker, and a clerk-stenographer. The funds required to support this work for the next three years are assured by a gift of $40,000 from the Laura Spellman Rockefeller Foundation.

A Medical School Dormitory for Harvard.

"Ninety-three men live as one of a group of students." This is a sentence taken bodily from the report of the Temporary Dormitory Committee of the Harvard Medical School Alumni Association. It represents, probably, one of the reasons why Harvard Medical School should be endowed with a "dormitory." The uninitiated, who are not able to understand from sentences such as this just why the committee recommend a dormitory, can nevertheless easily imagine the advantages of such an institution. The new Harvard building is to house 225 students in 200 rooms and is to include an assembly hall with seating accommodation for 500. As there is at present no large auditorium in convenient proximity to the buildings of the medical school, the projected hall is likely to prove very useful. The cost of buying the site and erecting the dormitory will amount to close upon one million dollars, a sum which is to be raised among Harvard medical graduates and their patients.

American Posture League.

It has been the consistent policy of the American Posture League to combat ill-shaped boots, badly tailored coats, deforming corsets, and other enemies of posture by promoting the advertisement and sale of clothing which they have approved. A firm is found which is willing to coöperate—and such firms cannot be difficult to find—whereupon a committee is appointed by the League to investigate the anatomical requirements and the most satisfactory method of meeting them. Thus, by the committee on shoes there were secured tracings of several thousand average feet, including the feet of Indians and Chinese who never had worn any footwear. Three categories of feet were found, represented in men and women alike and among the unshod as well as among the civilised. A firm was found willing to issue footwear of the three types designated inflare, straight, and outflare, and their products are now sold with the official approval of the League. The latest development along this line is announced in their annual report, just published. It is the Postur chair, built of steel with a wooden seat. The latter is adjustable both as regards height and declination. The back is designed to support the sitter in the small of his back, and is so hinged to the seat that it always conforms to the ideal posture, though its height is adjustable through one and a half inches to conform to the sitting height of the individual. These chairs are made in varying heights and should meet the requirements for industrial seating in the legislation of various States.

---

COLLEGE OF PHYSICIANS OF PHILADELPHIA.—The College announces that the next award of the Alvarenga prize, amounting to about $300, will be made on July 14th, 1924, provided that an essay deemed by the Committee of Award to be worthy of the prize shall have been offered. Essays intended for competition may be upon any subject in medicine, but cannot have been published. They must be typewritten, and if written in a language other than English should be accompanied by an English translation, and must be received by the secretary of the College on or before May 1st, 1924. Each essay must be sent *without signature*, but must be plainly marked with a motto and be accompanied by a sealed envelope having on its outside the motto of the paper and within the name and address of the author. It is a condition of competition that the successful essay or a copy of it shall remain in possession of the College; other essays will be returned upon application within three months after the award. The Alvarenga prize for 1923 has been awarded to Dr. Edward P. Heller, Kansas City, Mo., for his essay entitled Treatise on Echinococcus Disease.

THE PANEL CRISIS.

FURTHER CORRESPONDENCE BETWEEN THE MINISTER OF HEALTH AND THE INSURANCE ACTS COMMITTEE.

THE following letter from the Minister of Health, dated Oct. 26th, has been received by the Medical Secretary, British Medical Association:—

I have read two letters from you in the press upon the dispute, I will not say between us, but regarding the position and payment of panel doctors. This dispute is, if you will forgive me for saying so, both undignified and unprofitable, as I am quite convinced that you and I are really animated by the same desire—namely, to do what is best for the country as a whole. Before, therefore, the suggested "strike"—a word of ill omen as applied to your great profession—is made effective, I am very desirous that the profession, the societies, and the public should realise what my position is and on what it is based.

As Minister of Health, what I have to aim at is to secure the best medical service I can without putting undue strain on the taxpayer, the employer, and the insured person, who are all partners in the matter. The medical profession, on their side, naturally desire to obtain the utmost remuneration consistent with their views of fairness. The societies, on their side, naturally desire to obtain as much advantage as possible for the millions of insured persons under the provisions of the National Health Insurance Acts. I have to take account of both standpoints, but the final test for me is what is best in the public interest. What have I done? I found the controversy in being when I came to the Ministry of Health. At once I took steps to acquaint myself with the position, and studied the claim made on behalf of the profession in August. I saw both the Consultative Council of Approved Societies established under Order in Council to advise me on insurance questions, and other representatives of the approved societies, and I finally saw the Insurance Acts Committee of the British Medical Association.

Two things had to be considered: (1) What is a fair price to pay the practitioner for his services? and (2) what is the position of the insurance funds? The profession claim that at least 9*s.* 6*d.* is the fair price. A considerable body of opinion among the approved societies claims that 7*s.* 3*d.* is the fair price. I decided that 8*s.* 6*d.* for three years or 8*s.* for five years is the fair price, and offered it, giving my reasons fully. But I was not so foolish as to make the offer before seeing what is the position of the insurance funds. In these days of unemployment and over-taxation, I simply cannot ask the Government for a further subsidy, or put on extra contributions, unless the paramount public interest says that I must get more money in one way or the other. A great many statements have been made in various quarters as to reserve funds in the National Health Insurance accounts, out of which it was claimed that a fee of 9*s.* 6*d.* or more than 9*s.* 6*d.* could easily be found for the doctors. The famous millions which bulk so largely in the controversy consist mainly of a reserve fund built up by payments of the younger insured people, who in their earlier days are not often disabled by illness. But the fund is actuarily essential to meet the heavy claims of later years at an age when sickness is almost certain. Clearly this fund cannot be touched.

Then there are various smaller funds, some reinsurance funds like the Central Fund, some like the Deposit Contributors Fund and the Exempt Persons Fund, held for special small sections of the insured population, but not one accruing from unpaid doctors' fees, as has been suggested since the whole of the money found for fees, even in respect of insured persons who do not select a doctor, is distributed each year to the doctors on the panels. All these matters were fully investigated, and after consultation with the Government actuary, I found that the fee which seemed to me fair on the merits could reasonably be charged to the funds for a limited period, without endangering the benefits either statutory or additional secured to the insured. First, therefore, I came to a decision on merits. Then I found that the money was available. Then I made my offer, and I stand by that offer.

Now I come to the suggestion that the question should have been referred to arbitration. This was obviously an easy way for a Minister out of a difficult question. But is not one of the cardinal points which you are now making that the profession in this matter of remuneration, while agreeing that if I like, I can consult the approved societies, wishes itself to be clear of them? If arbitration ensues, then there must inevitably be three parties—the Minister, the profession, and the approved societies. You will have to come into direct relation with the societies, whether you like it or not, and in refusing arbitration I have, in fact, to a great extent been thinking of your standpoint, feeling that it would easily put you and the societies in a position good neither for you nor for them, nor for your patients.

In this connexion I call your attention to your statement in your letter published in the *Times* of Oct. 22nd : "If it is firmly and irrevocably understood that the question of the kind of medical attendance to be given under the insurance system and the payment for it is a matter to be decided, not by the approved societies or under their financial pressure, but by the Minister of Health, after consultation with all parties concerned, &c." This is the attitude I have throughout the controversy taken, neither more nor less. But the moment I make a decision in accordance with your own view of the Minister's duty, you say it is an offer which you cannot accept.

You go on to suggest that some concession should be made to the peculiar conditions of rural practitioners. Are not the officers of this department discussing that very matter with you at this moment with the earnest desire to arrive at a satisfactory conclusion ? Have they not told you that I personally intend to do all in my power to improve the position of the rural practitioners ? Finally, may I add that I am not enamoured of the panel system, and if the doctors would prefer at an earlier date than was anticipated a full inquiry into the best method of dealing with medical benefit, including, of course, the question of doctors' fees, I am willing to submit to my colleagues in the Cabinet a proposal for an early Royal Commission on the whole subject, and to undertake that the fee now suggested should be reconsidered in either direction as soon as the Commission reports.

A reply as follows, dated Oct. 27th, was sent by the Medical Secretary to the Minister :—

I am obliged by your letter of the 26th instant, and I agree that the dispute on the position and payment of insurance practitioners is unfortunate. It is, however, none of our seeking. The medical profession hates this periodic dragging of its affairs before the public, and would go a long way to avoid it, but it seems to be inherent in the constitution of the panel system. One of the reasons which has compelled us to make a stand on this occasion is to minimise the risk of future exhibitions of the kind.

I note your use of the word "strike," which I would point out is entirely misleading. The resignation of doctors in present circumstances does not mean that they will cease their work for their patients, but merely that they cannot do it under the conditions offered. Let me say quite definitely that the main point at issue is not the money, though I am convinced that your present offer is inadequate. The main object with which we are pursuing this dispute is to maintain a good medical service for the industrial population, and to have it settled once and for all what is the relation of the approved societies to the medical service and the doctors who provide that service. You say that your attitude has been that the question of "the kind of medical attendance to be given under the insurance system and the payment for it is a matter to be decided not by the approved societies or under their financial pressure," but by yourself after consultation with all parties concerned. But the fact remains that the approved societies are threatening you with all sorts of consequences if you take more than 7*s.* 3*d.* (or perhaps they will graciously allow you to make it 8*s.*) out of what they are pleased to call "their funds," and responsible leaders of the societies are saying to the public that the doctors' demand may mean bankruptcy to some of the smaller approved societies. One responsible organ of the insurance world declares that "if 9*s.* 6*d.* is paid to the doctors the insured person is being robbed of additional benefits for the advantage of the doctors." Can you wonder that in face of the growing pretensions of the approved societies we believe that whatever you or they may say, the societies are in effect demanding to be made the arbiters of the price that is to be paid for the medical service under the National Health Insurance system, and the medical profession will never allow such a position to be established either implicitly or explicitly.

I am sure that before this dispute is ended it will be necessary for you to make it plain by legislation, or in some way other than the declaration of even a responsible Minister —because Ministers change—that the position is not such as the approved societies claim ; that medical benefit is the basis of the whole National Health Insurance system ; and that the conditions of this service and the remuneration to be paid for it are matters to be settled by the community and not by any section of the community.

As to the question of the capitation fee, I am bound to say that you have entirely failed to convince any of us that 8*s.* 6*d.* is the equitable fee, taking all present circumstances into consideration. The profession regards the award of the arbitrators in 1920 as the bed rock from which it starts, and no amount of calculation by experts will convince either the doctor or the man in the street that 8*s.* 6*d.* will buy now, or is likely to buy within the next year or two, what 11*s.* bought in 1920. We are, however, still prepared to enter into negotiations with you, as representing the community, as to the exact value of the services we are asked to render. We do not, however, consider that being presented with a decision which we are told to accept or refuse is the same thing as negotiating. Moreover, the profession has convinced itself that there is in the National Health Insurance Fund sufficient money to pay the present fee of 9*s.* 6*d.* or even more, if the basic and essential nature of medical benefit be firmly established.

A good many wild statements have been made about the millions in reserve. So far as I am aware no responsible person on our side has suggested more than that the unexpectedly low demands on sickness benefit and the unexpectedly high rates of interest earned by the fund have given the Ministry a margin with which they could quite well pay the present fee without infringing on any of the benefits that are now being given to insured persons and without calling upon either the State, the employer, or the insured person for any additional contribution. I am not aware of anyone with authority to speak for the doctors who has suggested that there is a fund accruing from "unpaid doctors' fees" out of which the money now required ought to be found. We who speak for the profession know that all the money put into the central pool for the payment of doctors is distributed each year to the doctors on the panels.

Your suggestion that arbitration, if granted, would necessitate the approved societies coming into the matter is one which I cannot admit for a moment. It could only be admitted if you were to give our case entirely away by agreeing that the money paid to the doctors for providing a national health service for a large section of the community is taken out of a fund belonging to the approved societies. We cannot admit this. We feel that such was not the intention of Parliament, and if we are proved to be legally wrong it is, in my opinion, essential that the position should be altered at once. You will never get a contented medical service if the approved societies are to be placed in this position. We are quite ready for arbitration at any time on the lines of 1920—namely, as between the Minister and ourselves.

I gladly acknowledge that the officers of your department are at the present engaged in discussing the peculiar conditions of rural practitioners. I sincerely trust that you may be able to meet their exceptional and legitimate demands. I also freely acknowledge the personal interest you have shown in this matter.

Finally, let me say that the profession is prepared for a full inquiry, either Departmental Committee or Royal Commission, at any time you like, provided it *is* a full inquiry which will take into consideration not only the doctors' fees but the administration of the Act all round. It is, however, not usual, I believe, to suggest that a party to a dispute should accept a reduction in remuneration pending the report of an inquiry. I venture to suggest that you should follow the ordinary course and leave the capitation fee as it at present stands until the Royal Commission or other body appointed has reported. We should, of course, be willing to be bound by the report of such a commission, just as we would by the opinion of independent arbitrators dealing with this matter as between ourselves and you.

The Proposed Terms of Service:
Mr. H. S. Souttar's Address.

Presiding over a discussion at the Marylebone division of the British Medical Association on Oct. 26th, Mr. Souttar said that the alternative subjects—"The proposed terms of service of the panel practitioner" and "The future of the panel and the hospitals"—proposed for discussion arose from the uncertainty which existed as to the precise course of events, and he went on to say :—

But I venture to think that the alternatives are merely different aspects of the same subject. Indeed, for those who have studied the question at issue it is difficult to escape the conclusion that the future of the whole medical profession is bound up in the present conflict. It is no question of a sixpence less or a sixpence more that is at stake. The issue we are fighting is to determine whether we shall be the servants of the State or of the approved societies. If we lose, these wealthy corporations will be left absolute masters of the national insurance of our country, the Ministry of Health will have to do their bidding, and I ask you how long will it be before our great hospitals are absorbed under the title of additional benefits. If we win, as I am convinced we shall, we shall be able to dictate our own terms and to lay the foundations of a thoroughly sound medical service, in which every section of our profession will be proud to share.

There are those who would have us believe that compulsory insurance is altogether wrong, and that contract service is altogether humiliating. Such men to my mind must lack both knowledge and imagination. The working man is absolutely unable in most cases to meet his doctor's bill when he is ill, and in the old days it was a regular practice in industrial areas for the doctor, having cured his patient, o send a collector round to dun him every week until the bill was worked off. Surely it is more in keeping with the elf respect of both doctor and patient that he should pay whilst in health, and know when he is ill that the service he receives is no charity and yet involves no debt. Those who have the widest experience of insurance practice tell me that compulsory insurance is the only basis on which our working class can get an efficient medical service, and common sense tells me that they are right.

With those who maintain that all contract service is humiliating I find it difficult to speak with patience. On what basis may I ask are our judges, our administrators, our civil servants paid, unless it is a contract for services rendered to the State ? Of course there are black sheep in every fold. They have even appeared in Harley-street. But those who condemn wholesale the contract system should remember that they are condemning the work of 4,000 members of our profession, perhaps on the evidence of a neurotic housemaid. I know personally of panel practices in Buckinghamshire, in Dorset, and in Stepney, run as clinics of the most modern type, with specialist ervices and with an equipment of a very high order. The fact is that contract work enables a man to treat his practice as a business proposition. He is certain of a definite income and it pays him to be efficient. The more efficient his arrangements the easier will be his work, the larger his practice, and the greater his return. The dignity seems to me to be far more with the contract man than with him whose practice is a series of windfalls.

I hold then that insurance for the patient and a contract for the doctor are essential in industrial practice. But what are the essentials of the contract ? I think they are two. He must be adequately paid and he must be free from commercial control. As to what constitutes adequate payment I do not propose to discuss. It must compare with the eturns of private practice, it must be sufficient to attract men of a good class, and it must be sufficient to enable them o live in circumstances agreeable to the important services hey are rendering to the State. Nothing could be more disastrous than a national insurance with an ill-paid and dissatisfied medical service. I will only ask this one question : Can the State afford such a service ? The answer is contained n the fact that the funds now accumulated by the approved ocieties total 100 millions, and that this reserve is being added to at the rate of 7 or 8 millions a year. How much of that great reserve is due to the labours of those very men whom these societies now revile as incompetent and proclaim as robbers ?

But even more important is the freedom of the doctor from commercial control. He must be the acknowledged ervant of the State, the man to whom is entrusted the health of his country. His certificates must pass as sterling, and not be liable to the control of penurious officials. And he must be able to obtain freely for his patients all that modern science can afford.

It is here, Mr. Souttar concluded, that we really ouch on the future of the panel. To my mind the panel system at present is only half a service. National health insurance can never be complete until the hospitals with their great resources form a part of it, until the patient passes naturally and by ight from his doctor to the hospital, when its special services are required. It will be a great day for the hospitals, for they will then be adequately paid for the work they do, and their financial difficulties will be over for ever. And it will be a great day for our profession, for we shall all take our share as members of one great national medical service. It is for this hat we are fighting, and I venture to think that it is a prize worthy of great effort and of great sacrifice.

THE ALLEGED APPROVED SOCIETY "CONTROL."

"Control" is a difficult word to define, and the acquisition of power by one section of the community over another may be an insidious process. It seems convenient to set out once again the sequence of events in regard to the relation of approved societies o medical benefit.

Local Administration of Medical Benefit.

The actual day-to-day administration of medical benefit is carried out by the local insurance committee, which (subject to instructions from the Ministry of Health) administers the Acts, regulations, and departmental decisions for the time being in force ; that is to say, as regards matters more closely affecting the insurance doctor it merely administers the decisions of principle which have, ex hypothesi, been arrived at centrally after central negotiation between the Minister and the representatives of the profession. As regards some of these questions the committee can act only in agreement with the panel committee. The committee is also responsible for making the necessary cash payments to the doctors, and for this purpose it receives from the central practitioners' fund the amount which the Minister, on the advice of the central distribution committee, has allotted to the area, this amount being shared out to the individual doctors of the area according to the terms of a local "distribution scheme" which is prepared jointly by the insurance committee and the panel committee. The actual day-to-day administration of medical benefit is thus not, in theory at least, under the control of the approved societies.

Constitution of the Insurance Committee.

We have seen how medical benefit for each area is administered by the local insurance committee. Insurance committees are so constituted that the approved societies, although having no officially recognised "control," can (and therefore do) largely influence the practical local administration of medical benefit. The committees vary in size from 20 to 40 members. Of these, three-fifths represent insured persons, and these representatives are mainly chosen by election and nomination by or through approved societies. The medical profession, on the other hand, is represented by two doctors appointed by the local medical committee, one appointed by the county or county borough council, and (if the committee numbers 30 or more) one appointed by the Minister. The remaining members consist of nominees of the local council, representatives of the chemists, and women members appointed by the Minister. This preponderating voice on insurance committees of representatives of insured persons does not, however, constitute the "control" to which the profession has more recently taken exception. The doctors have, it is true, frequently urged that their representation on insurance committees is inadequate ; yet it is recognised that the profession has in each area two committees of medical men—the local medical committee and the panel committee—which have to be consulted by the insurance committee on professional questions. Moreover, it was generally felt that, at any rate until 1922, all substantial amendments to the Acts and regulations which affected insurance practice were the subject of discussion and negotiation between the Minister and the representatives of the profession.

The New Factor Introduced in 1922.

In 1922 a new factor was introduced owing to a shifting of the sources from which insurance practitioners were paid. The original Act of 1911 proposed that the Exchequer should find two-ninths of the cost of medical benefit, but even before medical benefit had become operative the Exchequer contribution had to be increased to four-ninths, while under the Act of 1920 the State contribution was nearly 6*s.* 6*d.* out of a total of 13*s.* 9*d.* In 1922 the remuneration of doctors and chemists was reduced, and this reduction was used in its entirety to relieve the Exchequer. The Geddes committee, however, recommended that the Exchequer should be still further relieved, and that its contribution should be limited to the original two-ninths provided for by the 1911 Act. This might have been effected by increasing the weekly contributions of employer and employed, but in fact the consultative council to the Ministry, which embodies approved society experience, recommended that the contributions should be maintained at their existing rate and that, until the end of 1923, *the balance should be met out of the accumulated surpluses in the benefit funds of approved societies.* The National

Insurance Act of 1922 gave effect to this proposal, subject to a provision whereby the benefit funds were reimbursed, to the extent of one-third of their contributions, out of a central fund controlled by the Minister. Thus there was introduced the significant innovation that the surplus funds of approved societies might be used towards providing the general practitioner treatment which forms a part of the normal medical benefit of insured persons.

The Demands of the Approved Societies.

Concurrently with this proposal there arose a demand among certain approved society interests that, as the societies were to be called upon to contribute towards the provision of general practitioner treatment for their members, they should be given some direct and definite control over the conditions and terms of this service, and, in particular, that they should participate in any central negotiations which might precede any future alteration in the terms of service of insurance practitioners, including, of course, an alteration in the rate of remuneration. This demand has been increasingly urged, and much pressure has been brought to bear on the Minister of Health. It is this contemplated control or influence by the societies over the future conditions and development of medical benefit generally, and of insurance practice in particular, that the medical profession has consistently opposed.

A Public Definition Required.

No Minister of Health has yet publicly defined to what extent, if at all, the claims of the societies in this matter should or will be met. Sir Alfred Mond, on the second reading of the 1922 Act, said :—

> "Having regard to the provision in this Bill for contributions in relief of State expenditure from the surplus funds of approved societies, I think that it is no more than fair and reasonable that I shall give the societies an opportunity of expressing their views before any new terms of service are made with the panel practitioners. But the responsibility for accepting these contracts rests and will continue to rest with the Minister of Health. . . . There is no word in this Bill which modifies the existing statutory provisions."

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg.-Comdr. E. R. Grazebrook is placed on the ret. list with rank of Surg. Capt.

W. F. Beattie is reinstated on the Active List as Surg. Lt.-Comdr.

Surg. Rear Admiral E. J. Finch is placed on the ret. list at own request.

Surg. Capt. F. J. A. Dalton to be Surg. Rear Admiral.

Surg. Lt. (D.) F. R. McCambley to be Surg. Lt.-Comdr. (D.).

ROYAL NAVAL VOLUNTEER RESERVE.

G. K. MacLennan, late temp. Surg. Lt. (D.), is transferred to the Permanent List.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. and Bt.-Col. Sir M. H. G. Fell relinquishes the temp. rank of Col.

Maj. R. H. MacNicol is placed on the half-pay list on account of ill-health.

TERRITORIAL ARMY.

Capt. R. H. Hadfield (late R.A.M.C.) to be Lt., and relinquishes the rank of Capt.

Capt. L. F. E. Jeffcoat (late R.A.M.C.) to be Capt.

Lt. F. J. Lidderdale to be Capt.

ROYAL AIR FORCE.

The undermentioned are granted short service commissions as Flying Officers : T. V. O'Brien and F. W. G. Smith.

The undermentioned are granted temporary commissions in the ranks stated : A. G. Lovett-Campbell to be Flight Lt. (hon. Squadron Leader) ; and G. R. Hall Flying Officer (hon. Flight Lt.).

Flight Lt. G. W. Allen (Capt., Army Dental Corps) relinquishes his temporary commission on resigning his commission in the Army.

INDIAN MEDICAL SERVICE.

The King has approved of the retirement of Maj. G. Tate on account of ill-health, and of the resignation of Lt. H. McNair.

Correspondence.

"Audi alteram partem."

THE FOUNDER OF THE LANCET: A PERSONAL REMINISCENCE.

To the Editor of THE LANCET.

SIR,—It is surely improbable that any other in our profession than my aged self who was in personal touch with the Founder of THE LANCET can yet survive in the flesh.

In 1812 "Tom," as I always heard him called, shared rooms in a small house built against St. Saviour's Church with Edward Heinekin and my father, John Grabham, as students at the Borough hospitals—then united. Both Heinekin, a profound naturalist, and Tom died at Madeira, where I still represent that bygone trio.

My first sight of Mr. Wakley was at a famous inquest when, as a boy, I was taken by an elder brother to that scene of seething excitement. Wakley, then M.P. for Finsbury and coroner for the district, went into his own witness-box, and I think did much by his terrific declamation to alienate everyone and to crush an adverse verdict in violation of the general consensus of surgical opinion. In the autumn of 1861 I was taken from the house surgeoncy at St. Thomas's, stuffed with knowledge but callow in worldly ways, to spend the winter at Madeira with Sir Julian Goldsmid and his consumptive brother. Mr. Wakley, who had developed pulmonary disorder, came with us, and Tom the second (T. H. Wakley, F.R.C.S.) confided his father to my care. We sailed on Oct. 8th in a small auxiliary steamer called the *Dane*, a 500-ton boat indicative of the embryonic stage of development of the now Union-Castle monsters, and arrived at Madeira, after a heavy gale, in nine days. The old man soon found out that I was well equipped in pulmonary matters, and we became warmly friendly. In those days we had no clinical thermometers, and no hypodermic needles, and I soon found that the bulk of those who crowded Madeira at that time had been brought up on kacoplasm and Blasius Williams. Wakley had extensive lung disintegration, and, though he improved to some extent, a modus vivendi with existing conditions was the most to be expected.

Besides Sir Julian Goldsmid and his brother I had in those days two companions—namely, Charles Tawney, senior classic of his year, and Cecil Monro, fifth or sixth wrangler and both Fellows of Trinity, Cambridge. We rode together every morning and paid our LANCET friend a daily visit before luncheon to listen to his sparkling denunciations of all things, visible and invisible. These explosions, perfect specimens of storm language, seemed necessary to his comfort, and he would grip my shoulder if I betrayed any impatience. His ponderous frame, searching eyes, and vivid animation held us spellbound as he changed with lightning speed from grievance to grievance. He told us story after story of the country general practitioner—"Go and bleed him and say I am coming"—and made us wonder how with so little knowledge and appliance such a good fight was made against disease in those days. Fraud and adulteration touched him to the quick, and he soon found out that the Madeira wine merchants were exporting on a grand scale though the vineyards there, destroyed by blight, no longer produced a single pipe of legitimate wine.

All efforts to help Wakley as a patient were futile, for he was impatient of any treatment or restraint. He lived through that winter, but succumbed in May, 1862, to copious hæmoptysis resulting from intense excitement. His body was sent for burial in England after an imperfect process of "embalming." It fell to me afterwards to introduce a strong solution of zinc chloride, which I injected into the femoral arteries, giving them a perfect preservative without evisceration when circumstances required. I sat with him during his last illness, but he was depressed and disappointed and spoke little.

In later years I saw much of the second Tom from time to time. He loved good music and had a piano in his office in the Strand. Moreover, he would occasionally come and sit with me in the organ-loft at St. Paul's Cathedral. In that memorable winter, 1861–62, the British community at Madeira was an interesting microcosm of diverse opinion. The ecclesiastic element was strong and twofold, one faction, noisy and aggressive, crushed us with an unmitigated mosaic cosmogony; the other required our passive acquiescence in whatever decision the Church might promulgate in all matters relating to creation and evolution. Some of us had read the "Vestiges," and my copy of the "Origin"—the first in these latitudes—was in great request; but it was the rash encounter of "Soapy Sam" with Prof. Huxley which really stimulated public interest in Charles Darwin, and led men to reflect that the cradle of every new science had always been encumbered with the corpses of extinct theologians. The focus of our party was the gifted Savilian Professor of Astronomy of those days, and we kept our views and studies to ourselves. Tom said nothing.

As time went on I became personally acquainted with the protagonists of progressive knowledge, and it fell to me eventually to touch copiously on these matters when addressing the Geological Society on behalf of the Royal College of Physicans of London, and I thoroughly enjoyed the sparkling interest of Lord Kelvin in records which for many years he had attempted to amalgamate with unbending Presbyterianism. Wilberforce never held up his head again, nor did Owen after the hippocampus minor fiasco; but the bishop's ever-ready wit charmed us all and went far to condone his subtle superficiality and questionable sincerity.

I could write volumes on the men and matter of those days, but I forbear.

Yours faithfully,

Madeira, Oct. 23rd, 1923. MICHAEL GRABHAM.

CENTENARY OF THE LANCET.

To the Editor of THE LANCET.

SIR,—THE LANCET celebrates its hundredth anniversary amidst a shower of congratulations and good will from the great medical community, in which I join from the other side of the Atlantic. It has been a century of untiring effort in the interests of science.

The reputation for impartiality justly conceded to consecutive editors encouraged beginners and unknown surgeons to bring the results of their labours into the daylight. Thus, by a farseeing discrimination, during a century, THE LANCET has saved valuable material from the scrap heap, and through its columns British surgery has reaped the reward.

THE LANCET has not only rescued much and many from unmerited obscurity, but it has broadcasted the work of great contributors for the benefit of all.

I am, Sir, yours faithfully,

W. I. DE C. WHEELER,

President, Royal College of Surgeons in Ireland.

Chicago, Oct. 20th, 1923.

To the Editor of THE LANCET.

SIR,—On behalf of my associates and myself I desire to have you extend to your editorial colleagues of THE LANCET our sincere good wishes and felicitations upon the completion of what we trust is only the first century of a noteworthy career of your honoured journal, a career certainly unmatched in the annals of medical journalism.

Fraternally and cordially yours,

GEO. W. KOSMAK, M.D.,

Editor of the *American Journal of Obstetrics and Gynecology.*

New York, Oct. 19th, 1923.

We have received the following cablegram from Kharkof, Russia, dated Oct. 26th:—

Journal, THE LANCET, *London*.

Our young journal, *Vratchebnoé Diélo*, sends congratulations to the honourable, old, but always in progress young, confrère on his Centenary, and, expressing deepest esteem, sends thanks from many Russian medical generations who got their education from the pages of THE LANCET.

(Signed) RÉDACTION.

INSULIN HYPOGLYCÆMIA.

To the Editor of THE LANCET.

SIR,—It is well known that insulin hypoglycæmia gives rise to symptoms both in experimental animals and in man. It is, I think, worth while recording the symptoms of an attack which I witnessed accidentally a short while ago and which was induced, without doubt, by insulin hypoglycæmia, because it is of the utmost importance that we should become familiar with the very varied manifestations of this condition. The symptoms exhibited by the patient, who is not under my care, were, I think, unusual. When first seen he was lying down out of doors on the grass, and as the day was fine and he had been taking moderately active exercise this did not seem peculiar. My attention was, however, attracted by the fact that he began shortly to throw his legs about in the air. On going up to him I found that he was sweating profusely, and was suffering from muscular spasms involving the face, trunk, and limbs. These were sufficiently violent to bend him double and to produce very marked contortion of the facial muscles. He was able to walk with assistance, but did so in a very wildly ataxic manner—the ataxia being apparently quite independent of the muscular spasms, which continually interrupted his progress. He was perfectly clear-headed, though naturally a little anxious. His pulse-rate was about 100; respiration did not appear affected except by the spasms. There was no real hyperpnœa or dyspnœa. He had with him four 5-gr. tablets of glucose, and had taken one of these before I saw him, the remainder were taken at once and were apparently quite without effect. In about 15 minutes from the beginning of the active symptoms we had arrived within reach of a sugar basin, and I gave him six lumps, one after the other. Within 10 minutes of taking them the attack ended, the patient expressed himself as feeling quite well and complained of being hungry. The cessation of the attack after the six lumps of sugar had been absorbed was most striking. So, too, the rapidity with which they appeared to act. The patient was taking large doses of insulin (60 units a day), 30 night and morning, and had once before experienced a similar attack but accompanied by loss of consciousness, which fortunately was prevented on this occasion.

I think this occurrence raises the question of the advisability of patients taking fairly active exercise after large doses of insulin, and most certainly illustrates the necessity for such patients to carry an adequate supply of carbohydrate with them in case of emergency.—I am, Sir, yours faithfully,

C. M. HINDS HOWELL.

Harley-street, W., Oct. 28th, 1923.

VICTOR HORSLEY LECTURE: THE LATE PROF. JOHN MARSHALL, F.R.S.

To the Editor of THE LANCET.

SIR,—I should like to think that there are many old University College men, besides myself, who have been pained by the cruel comments on Prof. Marshall made by Sir Edward Sharpey Schafer in his Victor Horsley Memorial Lecture.[1] In order duly to appraise Lister, was it necessary so wantonly to disparage Marshall? I attended the first three courses of Marshall's systematic lectures on surgery, and so informative and thought-awakening did I find them that I attended several lectures in two or three later courses. On the scientific side they were far ahead of any English surgical text-books at that time and for many years after. A more capable judge than I of the worth of Marshall's lectures was James Stanton Cluff, intellectually one of the most gifted men that ever entered the medical profession. He attended Marshall's lectures at the same time as myself. He took full notes in a cursive hand. These he afterwards carefully wrote out in elegant manuscript. After Cluff's premature and tragic death the notes became a prized possession of Marcus Beck's, and after Beck's death they were presented to the Library of the Royal College of Surgeons by Beck's intimate friend and colleague, Dr. Vivian Poore.

---

[1] THE LANCET, Oct. 27th, 1923.

In my opinion Marshall was a cultured, critical and scientific surgeon, ever ready to try new paths and explore avenues of fresh knowledge. He had been Fullerian Professor of Physiology at the Royal Institution and subsequently was appointed Professor of Anatomy at the Royal Academy. He served with special distinction a long term of office in the Council of the Royal College of Surgeons and exactly 40 years ago was elected its President. Still later he was awarded the highest honour in the franchise of the profession—namely, the presidency of the General Medical Council, an honour necessarily reserved to a very few men of exceptional ability and character.

How are we to account for this puzzling disparity of opinion respecting a contemporary by intelligent contemporaries? Sir Edward Schafer incidentally throws a little light upon the question. He says that when he attended Marshall's lectures "most of his audience were soon fast asleep. I was one of the sleepers." One word more. Sir Edward Schafer observed, "there is an admirable bust of him (Marshall) at Lincoln's Inn Fields." It is an admirable bust, but it is a replica of that presented by myself to University College on behalf of the subscribers of the Marshall Memorial Fund, of which Victor Horsley was prime mover and honorary secretary.

I am, Sir, yours faithfully,
JOHN TWEEDY.

Oct. 27th, 1923.

VACCINES IN CHRONIC OSTEOMYELITIS.

To the Editor of THE LANCET.

SIR,—The annotation on this subject in your issue of Oct. 13th as exemplified by Prof. T. Rovsing, of Copenhagen, corroborates the record set forth below of a truly remarkable case. In recording it I would like to emphasise the vital necessity of adequate vaccine treatment in very chronic cases of osteomyelitis.

My patient, whom I saw at the request of Dr. Shepheard Walwyn, of Carlisle, had had, one might fairly say, the best medical and surgical advice obtainable. Notwithstanding, his infection recurred over a period of 38 years, beginning in 1884, the last abscess being opened in 1921. Originally an osteomyelitis of the right femur, definitely asserted to be non-tuberculous by so great an authority as Sir James Paget (and subsequently so confirmed), this was followed in 1887 by swelling of the right humerus, which recurred in 1889. This swelling recurred in 1903 and in 1905 it was opened by Sir Anthony Bowlby. Mr. Bailey had cause to reopen and scrape the humerus in 1907, 1908, and 1909. In 1913 Mr. Paul opened an abscess in the thigh. Cultures showed streptococci and staphylococci. A vaccine was used, but insufficiently in my opinion. In 1919–20 an abscess formed near the knee and was incised, also another in the groin. This last was in connexion with the pelvic bone. In 1921 another abscess formed near the insertion of the psoas muscle. A few doses of vaccine were given and the *arm* swelled up, but fortunately subsided. The patient was tested by cutaneous injection for tubercle by Sir Thomas Horder, with negative results. I examined some pus from a superficial abscess of the inguinal glands in September, 1921, and found *Staphylococcus aureus*, *S. albus*, and *Streptococcus pyogenes*. I made a vaccine, and the dose, at my suggestion, was slowly worked up until by January, 1923, at least 12 doses of 1000 million organisms had been given.

There has been so far no recurrence. The record gives rise to hope that success has been attained, but it is not yet certain that such is the case. Prof. Rovsing does not favour vaccines in acute osteomyelitis. On the other hand, the work of the Pasteur Institute and Prof. Grégoire, as recorded in your issue of Dec. 6th, 1919, showed that vaccines of the right type have a definite and valuable rôle in aborting early cases. The technique has been well worked out and should strictly be adhered to. To quote Prof. Grégoire's words, "The picture is so different in these cases that they present quite peculiar features and are so mild as to make us doubt as to whether we are not dealing with a new disease."

Nevertheless, we must retain our balance and in acute cases be prepared to revert to surgery if abortive efforts fail. Some cases fail to respond to the best vaccine in the world.—I am, Sir, yours faithfully,

A. GEOFFREY SHERA.

Eastbourne, Oct. 25th, 1923.

THE ALBUMINURIA OF PREGNANCY.

To the Editor of THE LANCET.

SIR,—The extremely interesting article published by Dr. J. W. Russell in your issue of Oct. 27th, and other recent observations on the mechanical factors in orthostatic or postural albuminuria, tempt one to outline certain investigations which are being conducted along somewhat similar lines in connexion with the albuminuria of pregnancy. Although these latter are very far from complete, owing to a shortage of suitable cases and other unforeseen difficulties, it may be of value to compare notes with other observers even at this early stage. Thus one is already indebted to Dr. Russell for the particular method which he suggests in his paper; it is less direct than that which we have hitherto employed, but presents obvious advantages in cases where for one reason or another ureteric catheterisation is contra-indicated.

In reviewing the multitudinous data which have been collected with relation to the so-called toxæmias of pregnancy, one had been impressed with the apparent fact that albuminuria, although in a small minority of instances it may terminate in eclampsia, is *usually* unaccompanied by any other definite deviation whatever from the normal, with the possible exception of œdema. This applies alike to clinical and biochemical observations. It therefore seemed probable, in spite of the general rejection of the mechanical hypotheses which have been advanced by Paramore and others, that some simple explanation might account for the occurrence of uncomplicated albuminuria in pregnancy.

In cases of orthostatic albuminuria apparently due to lordosis, Sonne assumed that the two kidneys would not be equally involved, as the left renal vein would be more liable to compression by an anterior curvature of the spine, and indeed he was able to demonstrate by ureteric catheterisation left-sided unilateral albuminuria. Rieser postulated a compression of the left renal vein between the aorta and superior mesenteric artery in conditions of visceroptosis associated with lordosis. On these and other grounds it appeared not unlikely that a mechanical factor might determine the occurrence of albuminuria in certain cases of pregnancy and might be similarly demonstrated; consequently, with the coöperation of Mr. V. E. Lloyd, who has in each instance undertaken the actual catheterisation (by no means easy in advanced pregnancy), a small number of cases has been investigated along these lines. Our first observation, made in May last, showed a definitely positive result; urine from the left kidney was loaded with albumin, that from the right contained the merest trace. Further results have not been so satisfactory, although in several instances there has been very considerably more albumin on the left than on the right, and in no case has the position been reversed. We cannot therefore draw definite conclusions until our series is enlarged and other factors have been taken into account.

In expert hands ureteral catheterisation appears to occasion remarkably little inconvenience to the patient, and in view of the far-reaching importance of the subject we have considered it perfectly justifiable. At the same time one welcomes Dr. Russell's method of attacking the problem, as catheterisation is not always possible.

It is as easy to summon extraneous evidence to the support of a theory as it is to give scope to the imagination, and I will therefore resist the temptation to develop the thesis or to apply our entirely insufficient data to the pathology of eclampsia itself.

I am, Sir, yours faithfully,

FRANK COOK,
Beit Memorial Research Fellow.

Guy's Hospital, London, S.E., Oct. 29th, 1923.

"PRO LEPROSIS": INTERNATIONAL RELIEF WORK OF THE FRANCISCAN ORDER.

To the Editor of THE LANCET.

SIR,—The dermatological department of the University of Rome has just founded a philanthropic institution of the highest importance. It is the International Relief Work of the Franciscan Order to aid the missionaries who, voluntarily, devote themselves to the care of lepers abroad.

The work "Pro Leprosis" is an international work of charity and piety; it depends for its support upon the generosity of the rich, the small contributions of the less rich, and especially upon the science and sentiment of physicians who, more than anyone else, are in a position to appreciate the suffering due to the frightful infection of leprosy, and the service of missionaries, sisters of charity, and others who risk their lives in order to care for and treat their unfortunate brothers suffering with leprosy.

The physicians who desire to identify themselves with the international committee of the "Pro Leprosis" relief work are requested kindly to send their names to me, and to offer their opinions and suggestions as to the best manner to diffuse knowledge of this worthy cause in Great Britain and the United States of America, and to keep the work alive by conferences, articles in the press, university committees, ladies clubs, societies, &c. The editors of medical and scientific journals and writers for such publications, especially those on the subject of leprosy, are urgently requested to send gratis copies of such journals and articles to: Opera "Pro Leprosis" (Sezione Tecnico-Scientifica), Convento Sant' Antonio, Via Merulana 124, Roma, Italy. Contributions should be addressed to: Rev. P. Cipriano Silvestri, O.F.M., Direttore dell' Opera Francescana, "Pro Leprosis," Collegio Sant' Antonio, 124, Via Merulana, Rome, Italy, or direct to me at Via Cesare Battisti 133, Roma (1).—I am, Sir, yours faithfully,

Oct. 25th, 1923. Prof. VINCENZO D'AMATO.

LICE AND CRIME.

To the Editor of THE LANCET.

SIR,—I venture to endorse in every particular Mr. Theodore Dodd's conclusions, given in your issue of Oct. 13th, as to the grave nature of the lice menace. The council of the Incorporated Vermin Repression Society is fully alive to the part played by vermin, including body vermin, in the causation of disease and economic loss, but the subject is not one that enlists the sympathies of any but a few enthusiastic workers. Fortunately we have been able to obtain the sympathetic consideration of the Ministry of Health in regard to our attitude to lice in casual wards. The Ministry, replying (XII. 155416/23 date Sept. 25th, 1923), assures us that our representations respecting the proposed Casual Poor (Relief) Order, 1923, will be carefully considered by the Minister.

I am, Sir, yours faithfully,

ALFRED E. MOORE,
Hon. Director.

44, Bedford-row, London, W.C., Oct. 28th, 1923.

THE PEOPLE'S LEAGUE OF HEALTH.

To the Editor of THE LANCET.

SIR,—Remembering the generous response to the appeal on behalf of the sufferers in Japan, I now wish, on the eve of my retirement from office as Lord Mayor, to enlist the financial support of the public for the Endowment Fund of the People's League of Health, of which the King is patron.

The purpose of the League, which was founded in 1917 by Miss Olga Nethersole, is to multiply and supplement the sources of public information and education to such an extent that no mother shall lose her child through ignorance; that no man or woman shall be stricken with disease for lack of knowledge.

Recognising the national work that the League has undertaken in the interests of the people through the Trades Union General Council, the National Union of Teachers, and the Prisons and Borstal Institutions of the country, and as honorary treasurer to the Endowment Fund of the People's League of Health—to which the King has graciously contributed £100—I earnestly hope that the community will give a cordial response to this appeal which, as an official member of the League, it is my privilege to make.

Cheques can be sent to the Lord Mayor at the Mansion House and crossed "People's League of Health Endowment Fund."

I am, Sir, yours faithfully,

EDWARD C. MOORE,
Lord Mayor.

The Mansion House, London, E.C. 4, Oct. 25th, 1923.

Obituary.

GEORGE DARELL MAYNARD, O.B.E., F.R.C.S. EDIN., M.R.C.S. ENG.

THE death is reported from Johannesburg, Transvaal, of Dr. G. D. Maynard, who succumbed to cerebrospinal fever on Sept. 18th, at the age of 47. Dr. Maynard received his medical education at St. Mary's Hospital, qualifying in 1898, and later at Geneva and Paris. In 1901 he became F.R.C.S. Edin., and in 1904 travelled to South Africa, where he practised at first in the Cape Province and later became a railway medical officer in the Transvaal. At this period his interest lay especially in public health administration, and he became successively M.O.H. to the Pretoria Suburbs Health Committee and assistant medical officer to the Witwatersrand Native Labour Association, and later statistician to the South African Institute for Medical Research. After the war, in which he served as Lieut.-Colonel in the S.A.M.C. and D.A.D.M.S. to the Expeditionary Force in East Africa, Dr. Maynard took up consulting practice in cardiology, was placed on the staff of the Johannesburg General Hospital as honorary visiting physician, and resumed the editorship of the *Medical Journal of South Africa*, a post which he had previously held. He also held the position of medical adviser to the Statistical Department of the Government of the Union of South Africa. Dr. Maynard was one of the outstanding figures in South African medicine, and had gained his statistical equipment in a good school. His untimely death will cause regret in this country as well as in South Africa.

JORDAN ROCHE LYNCH, M.R.C.S. ENG.

WE regret to announce the death of Jordan Roche Lynch, who died recently from pneumonia at his residence in Barnes at the age of 80. He was the son of Dr. Jordan Roche Lynch, who practised in Farringdon-street, London, and who, in spite of his early death, was recognised as a pioneer of public health in the City of London.

Jordan Roche Lynch was educated at the Bluecoat School, and entered St. Mary's Hospital, Paddington, as a student in 1859, and qualified in 1864, thus making the fourth generation of his family to practise medicine. Shortly after he became resident medical officer to Dr. Sibson, for whom he had a lifelong regard, and afterwards was resident medical officer to the Lock Hospital. Leaving hospital work he went into practice at Notting Hill, where he remained for 50 years, retiring as recently as 1917. He was keenly interested in the welfare of his profession, and served on the medical committee of St. Mary's Hospital and also on the medical school committee of that hospital for 13 years, from 1878 to 1891. He was also for 27 years on the council of the Medical Defence Union. As a member of the council of the Royal Medical Benevolent Fund and other charitable organisations for many years he showed a practical interest in the medical charities. His experience of the happenings in the pre-Listerian days and his stories of his old hospital days were always of interest to the younger generations of the profession, who scarcely credit the changes which have occurred in the practice of medicine and surgery. His knowledge of the back history of medical professional work was directly derived from his father, who was one of the early collaborators in the production of THE LANCET under the Founder.

The late Dr. Jordan Roche Lynch married Marian, daughter of Mr. James Oliver, who survives him, and by whom he had five children, all of whom are living, one of the sons being Dr. G. Roche Lynch, pathological chemist at St. Mary's Hospital.

RICHARD JOSEPH TRISTAN, L.R.C.P. & S. EDIN.

BY the death of Dr. R. J. Tristan, on Oct. 25th, Retford loses a well-respected member of the medical profession. Dr. Tristan qualified in 1886, and held the post of resident midwifery assistant at Coombe Hospital, Dublin, before settling in private practice. He went to Retford nearly 40 years ago as assistant to the late Dr. William Pritchard, and his kindness and geniality brought him wide popularity. Dr. Tristan was a pupil and friend of the late Dr. Joseph Bell and Sir Henry Littlejohn, and many were the stories he delighted to tell of these men. He was a vigorous supporter of the National Service League, and took a keen interest in all matters military, having in his youth served in the Sherwood Yeomanry Cavalry and other corps. During the war he was the medical recruiting officer for Retford and district. He was a well-known member of several Caledonian societies. For many years he was a member of the medical staff of the Retford Hospital and Dispensary, and on his retirement from active work there he was made honorary consulting physician.

OWING to the prevalence of chicken-pox this year in Manchester, the Public Health Committee is asking for power from the city council to make the disease compulsorily notifiable for a period of six months, beginning in January next.

Dr. J. B. Mennell, of St. Thomas's Hospital, London, on Oct. 22nd opened a new massage department of the Royal Infirmary, Manchester, and expressed the hope that the honorary medical staff would coöperate in the use of the department, which would materially increase the efficiency of the institution.

ROYAL MEDICAL BENEVOLENT FUND GUILD.—The golf competition in aid of this Guild, which was open to any woman member of a recognised golf club returning the best aggregate of five selected cards against bogey (not necessarily on the same course) between Jan. 1st and Sept. 30th, 1923, resulted in a tie between Miss W. Doxford (Bromley and Bickley), L.G.U. handicap 7, and Mrs. Wright (Stanmore), L.G.U. handicap 20, with an aggregate of 29 holes up on bogey. Ties being decided on the greatest number of holes won from bogey on the five cards, Miss Doxford wins the silver rose-bowl presented by Sir Hugh Rigby, and Mrs. Wright the prize for competitors with handicaps over 18. The Guild benefits to the extent of over £135, and the committee hope to run a competition on similar lines next year.

THE MEDICAL INSURANCE AGENCY.

A MEETING of the Committee of Management of the Medical Insurance Agency was held at the house of the British Medical Association on Thursday, Oct. 25th, when, in the absence of Dr. G. E. Haslip owing to indisposition, the chair was taken by Dr. H. A. des Voeux. Other members present were Dr. E. Weaver Adams, Lieut.-Colonel R. H. Elliot, Dr. R. A. Gibbons, Dr. R. Langdon-Down, Sir Dawson Williams, Sir Squire Sprigge, and Mr. W. E. Warne. The secretary presented the audited balance-sheet for the year 1922, together with the chairman's report thereon. A very interesting detailed schedule showed the great and rapid progress made by the Medical Insurance Agency during the last eight years. The premium income increased from £12,104 in 1915 to £37,936 in 1922, whilst the commissions, &c., earned rose from £1950 in 1915 to £5250 in 1922. For the third year in succession policies totalling over £100,000 in sums assured in respect of life and endowment assurance were arranged through the medium of the agency, bringing the total sums assured up to Dec. 31st, 1922, under these heads to over £700,000. Business in fire and accident insurances has increased; the convenience of paying one premium for all household risks under a flat rate is apparently much appreciated. An interim report by the chairman for the nine months ended Sept. 30th, 1923, stated that the popularity of this comprehensive household contract continued. In spite of a decline in life assurance business experienced by all offices, and in spite of the existence of keen competition, the agency negotiated 62 new life policies during the period. One of the advantages—and not the least—of the Medical Insurance Agency is that members of the profession can obtain from it personal advice as to the particular kind of policy to meet the individual's particular needs. During the annual meeting at Portsmouth no fewer than 55 interviews took place, and it was found possible to adjust several delicate matters to the satisfaction of the applicant.

The amount of business in insuring motor-cars done by the Agency increased during the year, but bearing in mind the large number of cars now used by members of the profession it is believed that the amount could be further increased. Motor-car insurance is a specialised business; accidents are more heavy and frequent than in almost any other form of insurance, and members of the profession would be well advised to take advantage of the security offered them to obtain fair and equitable settlements by insuring through an agency so strong and influential as the Medical Insurance Agency. The committee has for some time felt that the benefits already conferred upon the profession might be increased were it in a position to obtain for the person insuring through it advice on all matters affecting the purchase and use of motor-cars. An arrangements has now been made with the firm of Mann, Egerton, and Co., Ltd., to advise members free of charge, either directly or through the medium of the Agency, on any problems, difficulties, disputes, or technical matters relating to motor-cars, including motor coach-work and accessories; to give advice as to the suitability of any particular car for any class of work or type of district; to undertake the periodical inspection of members' cars at a moderate fee; to give expert advice as to the mechanical condition of members' cars, and the advisability of repairs, and to prepare specifications and estimates for repairs to mechanism or coach-work, or for the manufacture of special bodies to meet particular requirements, and generally to place their entire resources at the disposal of members, both in London and throughout the country. The firm has been established over 25 years; it possesses experience, a staff of experts and large works at Ipswich, Norwich, and in London (156, New Bond-street, and 1a, High-road, Kilburn). The firm will place at the disposal of purchasers of cars, through the Medical Insurance Agency, their system of deferred payment; a purchaser pays 25 per cent. of the value on delivery and the balance by monthly or quarterly instalments as desired. An addition of 2½ per cent to the list price of the car is made to cover interest charges. The company has a stand (No. 129) in the coach building annexe of the Olympia Show, and its representatives will be prepared to give advice free of charge to medical men intending to purchase on the advice of the Medical Insurance Agency. Application for an introduction should be made to the Secretary of the Agency, 429, Strand, London, W.C. 2.

It appeared from the balance-sheet of the Medical Insurance Agency for the year 1922 that a sum of over £2000 had been returned by way of rebates to those insured through the Agency, an increase of £367 over 1921. The surplus carried to the Medical Benevolent Fund was slightly larger in 1922 than in the preceding year, and a sum of £1500 was allotted as follows: to the Royal Medical Benevolent Fund Guild, £630; to the Royal Medical Benevolent Fund, £315; to the Epsom College Benevolent Fund, £210; to the Royal Hospital and Home for Incurables, Putney, £52 10*s.*; THE LANCET Editor's Discretionary Fund for dealing with emergency cases, £25. A further sum of £267 10*s.* was set aside for the fund established by the Agency to make grants in aid of the education of girls, orphans of medical men, or daughters of unfortunate brethren who are precluded by age or ill-health from continuing to practise. Including the contributions now made the total sum subscribed to medical charities by the Medical Insurance Agency since 1910 exceeds £11,500.

THE RECENT SMALL-POX OUTBREAK IN LONDON.

The report of the Public Health Committee of the London County Council on the recent small-pox outbreak in London makes interesting reading. It appears that altogether there were 18 cases—two terminating fatally—of which 11 occurred in the County of London and 7 in extra-metropolitan districts. Attention was first directed to the appearance of small-pox in London on Sept. 7th, the patient being a girl employed as a chambermaid at a central London hotel. During the course of her duties at the hotel she had waited upon a lady visitor from Spain, who, in the absence of medical advice, was thought to be suffering from influenza, with spots attributed by her to fish poisoning. This woman left the hotel on August 19th and efforts were immediately made to trace her movements and destination. Before she was ultimately discovered on Sept. 10th at an address in an out-county suburb, two cases presented themselves which apparently were the result of contact with her. One patient was employed in the vicinity of the hotel where she had stayed and the other was actually employed at the hotel. When finally she was located, the local medical officer of health, on visiting the address, discovered an adult relative suffering from a severe attack of small-pox, and ascertained that the lady herself was out shopping in the West End of London. On her return she was found to be recovering from a mild attack of small-pox. On the same day another case was discovered in London, the patient being a relative who had been in contact with her. During the later period of her convalescence, before she was removed to hospital on Sept. 10th, this lady was visiting, shopping, &c.

Ten further cases afterwards occurred. Three apparently had no connexion with the original source of infection, but four were presumed to have been infected by the man who worked in the vicinity of the lady's hotel. Of the remaining three, one was a man employed by a laundry firm in washing soiled linen from the hotel, and the other two were adults who had occupied at different times the room at the hotel in London previously occupied by the Spanish visitor. The Public Health Committee of the Council conclude: "The medical officers of health in the various local areas had the assistance of the Council's experts in diagnosis, Dr. W. McConnel Wanklyn and Dr. J. A. H. Brincker, and took prompt measures to arrest spread of the disease, including the vaccination and observation of contacts. Vaccinations and revaccinations by public vaccinators of school-children in the schools directly or indirectly connected with the outbreak have also been carried out through the medium of the Council's divisional medical officers acting in coöperation with the board of guardians. Only one child of school age (an unvaccinated boy of 12 years) contracted the disease. As a result of the energetic measures taken the outbreak of small-pox in London was localised." Of the 18 cases which occurred, 12 patients whose ages ranged between 23 and 79 years had not been vaccinated since infancy, and of these 1 died; 5 between the ages of 12 and 50 years were unvaccinated, and of these 1 died. One patient had been vaccinated in the army in 1914, and suffered a very mild attack.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—An ordinary Comitia of the College was held on Oct. 25th, the chair being taken by Sir Humphry D. Rolleston, the President. It was reported by the Censors' Board that Mr. George Dawson Stilwell had been appointed Jenks scholar. The following candidates were admitted to the Membership of the College: Drs. C. K. J. Hamilton, D. Hunter, D. G. Leys, W. T. Nelson, D. Nicholson, E. O. A. Singer, and K. H. Tallerman. Licences to practise physic was granted to 168 candidates (including 33 women) who have passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Board, and have complied with the by-laws of the College. The following are the names and medical schools of the successful candidates:—

W. L. Ackerman, London; J. C. Ainsworth-Davis, Cambridge and St. Bart.'s; R. H. Amm, Cape Town and Guy's; R. S. Anderson, St. Bart.'s; F. G. A. Armson, Birmingham; I. Atkin, St. Bart.'s; W. Balendra, Ceylon and London; Rose Baranov, Univ. Coll.; P. E. Bardsley, Cambridge and St. Thomas's; J. S. Benzecry, Univ. Coll.; E. M. Bergheim, Middlesex; Dora M. Berry, Royal Free; E. J. Blackaby, St. Bart.'s; Margery G. Blackie, Royal Free; L. G. Blair, Edinburgh and London; W. L. Blakemore, Birmingham; D. R. Blunn, London; A. J. Boase, St. Thomas's; Hilda A. Bond, Univ. Coll.; E. G. Bradbeer, Bristol; R. T. Brain, London; A. Broido, Guy's; C. O. S. B. Brooke, St. Bart.'s; Georgie G. Brown, Aberdeen and Charing Cross; J. W. Brown, Middlesex; Mary Buck, Royal Free; B. H. Burns, Cambridge and St. George's; Lily C. Butler and Kathleen F. Butterfield, Royal Free; F. B. Byrom, London; C. M. Carruthers, Kingston and London; H. K. Christie, Otago; D. H. Cockell, St. Bart.'s; M. Cohen, Birmingham; B. A. Coles, Cardiff and Westminster; A. B. Cooper, St. Bart.'s; R. Cove-Smith, Cambridge and King's Coll.; I. S. Cristol, Leeds; G. J. Crosby, Cambridge and Univ. Coll.; D. T. Davies, Cardiff; I. G. Davies, Cardiff and St. Bart.'s; T. D. Deighton, St. Bart.'s; Margaret B. M. Dewhurst, St. Mary's; D. Diamond, St. Bart.'s; V. W. Dix, Cambridge and London; A. F. Doyle, St. Thomas's; Doris L. Durie, Univ. Coll.; Hilda R. Dutton, Bristol; N. L. B. V. Eckhoff, Cape and Guy's; L. C. J. Edwards, Melbourne and London; P. Ellman, Manchester; G. S. W. Evans, St. Bart.'s; W. M. Evans, Univ. Coll.; J. L. Farquharson and S. Farquharson, St. Thomas's; R. B. Fawkes, Cambridge and Guy's; H. G. Goldwater, Cambridge and Middlesex; T. S. Goodwin, Cambridge and St. Bart.'s; F. M. Gore, Birmingham; L. J. Green, Westminster; J. V. Griffiths, Cambridge and Durham; P. D. Griffiths and C. J. P. Grosvenor, Cambridge and St. Bart.'s; C. C. Halliwell, Cambridge and St. Thomas's; A. Harbour, St. George's; H. E. Harris, St. Bart.'s; Doris I. Harston, Royal Free and London; G. T. Henderson, Cambridge and Guy's; K. W. Heritage, London; G. Hochschild, Cape and St. Thomas's; Frances A. Hogben, Manchester; E. Holmes, Leeds; J. W. Hope-Simpson, Cambridge and St. Thomas's; Madge W. Hubble, King's Coll.; D. F. Hutchinson, Cardiff and St. Thomas's; L. I. Hyder, King's Coll.; C. Iszatt, London; C. Ive, Guy's; E. C. James, Cardiff; A. H. Johns, Cambridge and St. Bart.'s; C. E. Keast, Guy's; Karin L. E. Kellgren, Royal Free; G. B. Kirkland, Guy's; C. de Winton Kitcat and R. A. E. Klaber, St. Bart.'s; E. H. Koerner, Oxford and Guy's; P. E. M. Lanier, Middlesex; Miriam A. Lawson, Royal Free; J. J. Lewinstein, Guy's; R. H. Little, St. Thomas's; A. A. Lucas, Madras and Edinburgh; A. R. Macdonald and G. B. McMichael, St. Bart.'s; Margaret D. Mason, London; G. B. Matthews, Charing Cross; G. A. Metcalfe, Cambridge and St. Thomas's; H. D. N. Miller, Cambridge and King's Coll.; G. O. Mitchell and P. M. Moffatt, Guy's; C. I. N. Morgan, Cardiff and St. Bart.'s; O. G. Morris, Guy's; N. Moulson, St. Bart.'s; Jeannette F. L. Murray, Cape and St. Mary's; F. W. G. Nash, Middlesex; F. N. Newell-Roberts, Guy's; M. F. Nicholls, Cambridge and St. George's; J. R. Nicholson-Lailey, Bristol; Muriel L. M. Northcote, Royal Free; P. H. O'Donovan and R. J. Oliver, London; Mary E. Ormsby, Royal Free; Jean Orr-Ewing, Oxford and St. Mary's; Amy M. Parkinson, Charing Cross; J. Parrish, St. Bart.'s; T. W. Preston, King's Coll.; C. A. Probert, Guy's; R. J. V. Pulvertaft, Cambridge and St. Thomas's; P. G. D. Quinet, Birmingham; K. Rai, Lahore and Middlesex; W. A. Rankin, Edinburgh and Westminster; J. O. M. Rees and R. D. Reid, St. Bart.'s; W. L. Roberts, Cambridge and Univ. Coll.; H. A. Robertson, Oxford and King's Coll.; N. L. D. Robertson, King's Coll.; Sybil H. G. Robinson, London; T. Robson, Cardiff and St. Thomas's; D. J. Rose, St. Bart.'s; Marjorie Rushbrooke, Birmingham; Z. Salama, Cairo and Birmingham; F. H. Scotson, Manchester; J. M. Scott, St. Bart.'s; H. M. Shelley, Sheffield; A. E. Sherwell, Bristol; Mary M. Sillito, Royal Free; Lucy C. Simpson, St. Mary's; A. J. D. Smith, St. Bart.'s; N. R. Smith, St. Thomas's; L. V. Snowman, Cambridge and St. Mary's; A. C. Sommerville, King's Coll.; M. Stieber, Westminster; R. M. L. Still, Guy's; F. O. T. Strange, King's Coll.; E. R. S. Sweeney, Bombay and St. Mary's; Annie Sydenham, Royal Free; F. C. M. Taylor, Charing Cross; H. Taylor, Bristol; R. C. Taylor, Univ. Coll.; L. M. Teuten, Cambridge and St. Mary's; B. M. Toop, London; A. Turner, St. Mary's; H. F. Turney, Oxford and St. Thomas's;

Helen R. Turover, Charing Cross; F. C. O. Valentine and S. Vatcher, Cambridge and London; D. Vaughan, Guy's; Kathleen C. Vost, St. Mary's; R. G. R. West, St. Bart.'s; R. Whillis, Cambridge and Univ. Coll.; R. W. White, London; A. G. E. Wilcock, Cambridge and St. George's; Doris Williams, Westminster; E. L. Williams, London; Elsie J. Williams and Esther Wingate, Royal Free; J. Wolstencroft, Liverpool; T. Wooldridge, Guy's; and H. Yates, Cambridge and St. Thomas's.

Mr. A. C. Clauson, K.C., was appointed Senior Standing Counsel, vice Sir Thomas J. C. Tomlin, K.C., appointed Judge in the High Court of Justice. Dr. J. A. Nixon was appointed a representative on the Court of the University of Bristol, vice Dr. Newton Pitt, resigned. Dr. Arthur J. Hall was appointed a representative on the Court of the University of Sheffield, vice Sir Humphry Rolleston, resigned. The Senior Censor moved, and it was resolved: 1. That the licence of the College, which was withdrawn from Reginald Nitch Smith in 1918, be now restored to him. 2. That the licence of the College, which was withdrawn from David Arnold Chaning Pearce in January last, be now restored to him.

The President announced that he had appointed Sir Archibald Garrod to deliver the Harveian oration in 1924. The alterations in the by-laws relating to the examinations for the licence, as passed at last Comitia, were passed for the second time. Temporary by-laws were passed allowing David Waters Sutherland and John Cyril Holditch Leicester, being resident in India, to be admitted to the Fellowship in absentia any by-law to the contrary notwithstanding. Mr. Horace Barlow was appointed to the office of Bedell rendered vacant by the death of Mr. William Fleming. The following report was received from the Committee of Management and the recommendations made in it were adopted—

1. That a note be inserted at the end of Clause II., Chapter II., of the Regulations for the Diplomas of L.R.C.P. and M.R.C.S. to the effect that, "the course in General Biology required by Clause VII. 2 may be taken concurrently with the study for the Pre-Medical Examination, in cases where such study is taken at a recognised Medical School and Hospital."

2. That the Higher Certificate Examination of the Central Welsh Board be added to the list of Examinations in which the subjects of Chemistry and Physics may be accepted under the conditions of Clause 2, Section II., of the Regulations for the Preliminary Examination and for the Pre-Medical Examination.

3. That the Matriculation Examination of the University of Queensland be added to the list of Examinations recognised for the Preliminary Examination in General Education.

The Committee reported to the Colleges the retirement by rotation from the Committee, under the conditions of Para. VI., Part I., of the scheme for constituting the Examining Board in England, of Dr. J. A. Ormerod and Mr. H. J. Waring.—Dr. J. A. Ormerod was reappointed a member of the Committee of Management. After the reports of some Committees had been received and other formal College business transacted, the President dissolved the Comitia.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—R. S. Chambers, Guy's Hosp.; G. Israelstam, London Hosp.; T. J. Liengme, Lausanne; and D. Parsons, Charing Cross Hosp.

Medicine.—E. N. C. Annis, Guy's Hosp.; R. Caplan, Glasgow; R. S. Chambers, Guy's Hosp.; D. Dimitrijevitch, Oxford and St. Mary's Hosp.; S. Halperin, St. Thomas's Hosp.; G. A. Lord, Manchester; T. J. Liengme, Lausanne; M. A. E. Somers, Bristol; A. J. Vickery, St. Mary's Hosp.

Forensic Medicine.—E. N. C. Annis and R. S. Chambers, Guy's Hosp.; D. Dimitrijevitch, Oxford and St. Mary's Hosp.; C. J. Fox, St. Mary's Hosp.; S. Halperin, St. Thomas's Hosp.; W. M. Jones, St. Bart.'s Hosp.; Y. N. Lal, Dundee; T. J. Liengme, Lausanne; G. A. Lord, Manchester; and W. R. H. Pooler, St. Mary's Hosp. and Cambridge.

Midwifery.—H. J. Adams, Middlesex Hosp.; H. P. Burns, St. Mary's Hosp.; H. T. Chiswell, Guy's Hosp.; A. J. M. Davies, St. Mary's Hosp.; S. Halperin, St. Thomas's Hosp.; and T. J. Liengme, Lausanne.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: E. N. C. Annis, R. S. Chambers, T. J. Liengme, G. A. Lord, and W. R. H. Pooler.

MATERNITY CASES IN POOR-LAW INFIRMARIES.—The Finance Committee of the Manchester Corporation has approved and forwarded to the city council a proposal that the corporation should subsidise beds in the paying wards of the Poor-law institutions for maternity cases arising in families "lying socially between the Poor-law level and the well-to-do." The charge is three guineas a week, and the patients are expected to contribute about 50 per cent. of that sum. The exact amount to be so contributed, however, is to be considered independently by a subcommittee. The net estimated cost of six beds is calculated at £200, towards which the Ministry would contribute half; the Minister of Health has intimated that he will look with favour on the proposal, and will treat the expenditure as entitled to the 50 per cent. Government grant. Thus the net cost to the corporation will be small.

WELLCOME BUREAU OF SCIENTIFIC RESEARCH.—On the occasion of Dr. Andrew Balfour's retirement from the directorship a representative gathering of the staff was held at the Bureau on Oct. 29th to bid farewell to him and his deputy, Colonel G. E. F. Stammers, who is also retiring. On behalf of the staff Dr. C. M. Wenyon expressed the admiration and esteem which they all felt for their retiring Director-in-Chief and his deputy, and thereafter, as a token of regard, made a presentation to each of them. Dr. Balfour and Colonel Stammers, in thanking Dr. Wenyon and the staff, expressed a hope for the future prosperity of the Bureau.

A NEW HOSPITAL AT SHIRAZ.—A wealthy Persian merchant, Haji Mohammed Hussan Namazi, has presented to Shiraz a maternity hospital, the conduct of which he has asked the Church Missionary Society to undertake. Medical work at Shiraz was only opened in February of this year by the C.M.S., the work being undertaken at the invitation of the Indo-European Telegraph Department of the India Office, and this new department will mean increased responsibilities in an important centre with a population of 60,000 people. Dr. Emmeline Stuart, of Dublin, who went out last February to share the work at Shiraz, will be responsible for the hospital, together with Miss E. A. Thomas, and is at present at Yezd.

THE American College of Surgeons, on Oct. 26th, conferred its Honorary Fellowship on Sir William Ireland de Courcy Wheeler, M.D., F.R.C.S.I., President of the Royal College of Surgeons, Ireland, and on Mr. A. E. Webb-Johnson, C.B.E., D.S.O., F.R.C.S., Honorary Surgeon to the Middlesex Hospital, and Dean of its Medical School. Mr. Webb-Johnson is visiting the United States in response to an invitation to deliver an address at the Special Congress of the American College of Surgeons held at Chicago.

BIRMINGHAM AND MIDLAND EDINBURGH GRADUATES' CLUB.—The nineteenth annual dinner of the club was held on Oct. 25th at the Queen's Hotel, Birmingham, with the President, Dr. J. R. Ratcliffe, in the chair. Prof. Arthur Robinson was the guest of the evening and replied to the toast of the University in a speech in which, after giving delightful reminiscences of his own student life, he described the Edinburgh school as it is to-day, and indicated its probable development in the future.

LONDON (R.F.H.) SCHOOL OF MEDICINE FOR WOMEN.—The annual dinner of past and present students will be held at the Savoy Hotel, Strand, on Dec. 6th.

ROYAL DENTAL HOSPITAL OF LONDON.—The dinner of the past and present students will be held at the Trocadero Restaurant (Empire Rooms), London, W., on Nov. 24th, at 7 P.M. Mr. S. Northcroft will preside.

ST. THOMAS'S HOSPITAL: OLD STUDENTS' DINNER. The old students' dinner was held on Oct. 26th, at Prince's Restaurant, Piccadilly, when some 220 St. Thomas's men and their guests assembled under the chairmanship of Mr. W. H. Battle, consulting surgeon to the hospital. Among those present were Sir Arthur Stanley (treasurer), Sir Cuthbert Wallace (Dean of the Medical School and senior surgeon), Dr. C. R. Box (senior physician), Mr. G. Q. Roberts (secretary), Sir Charles Scott Sherrington, F.R.S., Surgeon Vice-Admiral J. Chambers (Director-General, Navy Medical Department), Lieut.-General Sir William B. Leishman (Director-General Army Medical Department), Air Force Commodore D. Munro, Sir George H. Makins, Brig.-General Sir William Horwood, Sir Havelock Charles, Lord Riddell, Sir F. Stanley Hewett, Mr. J. B. Lawford, Sir Hector Mackenzie, Sir Archibald Reid, Sir Seymour Sharkey, Dr. H. G. Turney, Mr. Percy Sargent, Prof. H. MacLean, Dr. G. A. Maling, V.C., Dr. Ingleby Oddie, Sir Squire Sprigge, Dr. N. G. Horner, Sir James Roberts, Dr. Seymour Taylor, and Lieut.-Colonel I. Boulger.

At the express desire of the chairman the speeches were few and brief, Mr. Battle setting the example by simply welcoming the company and stating that the treasurer of the hospital and the Dean of the Medical School would report upon the several and joint activities of the institution. Sir Arthur Stanley's reply showed the good reason that the old students of St. Thomas's have for knowing that the hospital is in a satisfactory and progressive state. Admitting lean times in the near past, he assured his hearers that acute financial troubles had been satisfactorily met, while a valuable move forward could be reported in that the hospital had been able to acquire suitable land and bank up enough money for the erection of a residential hostel. At least £3000 more, he thought, would be required, but the position justified an immediate start. Sir Cuthbert Wallace stated the position of the school, mentioning by name also the recipients of honours during the year and the school prizemen. He showed also that the school stood generally well in athletics, though for the moment the only challenge cup held by the hospital was the nurses' tennis cup. In respect of London medical education, he called attention to the fact that for the first time there had been a conference of all the licensing bodies to deliberate questions affecting their curricula, and he hoped that this would assist to a mutual recognition of each other's tests. In reference to the relation of the University of London to the constituent medical schools, he spoke of the necessity that the schools, if they were to play their best part in a coöperation scheme, should be left largely independent in their own houses. Sir Cuthbert Wallace concluded by welcoming the guests and proposing the toast of Mr. Battle's health, to which the chairman replied.

Leeds School of Medicine.—The fortieth annual dinner of the past and present men students of the school will be held at the Queen's Hotel, Leeds, on Nov. 16th, at 7 P.M., when Mr. Carlton Oldfield will preside. Tickets (10*s.* each) may be obtained from the hon. secretaries, Mr. A. M. Claye and Mr. W. E. Dornan, at the Medical School, Leeds.

A **lecture** on the Treatment of Rhino-Laryngological Tuberculosis in Finsen Light Institute, Copenhagen, with a note of results obtained, will be delivered by Prof. Strandberg, of Copenhagen, on Monday, Dec. 3rd, at 5.30 P.M., at the house of the Royal Society of Medicine, 1, Wimpole-street, London, W.

Rontgen Society.—A general meeting will be held on Nov. 6th, at 8.15 P.M., in the Institution of Electrical Engineers, Savoy-place, Victoria Embankment, London, W.C., when the presidential address will be delivered by Sir Oliver J. Lodge, F.R.S., on X Rays and the Atom.

Departmental Committee on Preservatives and Colouring Matters in Food.—The Minister of Health has appointed Mr. P. A. Ellis Richards, F.I.C., President of the Society of Public Analysts, to be a member of the above Committee in the place of Mr. Otto Hehner, F.I.C., who has resigned from the Committee, having to return to South Africa.

People's League of Health.—A series of eight lectures are being delivered at the headquarters of the National Union of Teachers, Hamilton House, Mabledon-place, London, W.C., under the general heading of the Mind and What We Ought to Know About It. The first lecture was given by Dr. Bernard Hart on Oct. 31st on Primitive Instinct, and will be followed by further lectures at 6 P.M. every Wednesday until Dec. 19th, on which day Dr. A. F. Tredgold will speak on Mental Deficiency. Others taking part in the course are Dr. R. H. Cole (Nov. 7th), Dr. R. S. Rows (14th), Sir Maurice Craig (21st), Sir Robert Armstrong Jones (28th), Sir Frederick Mott, F.R.S. (Dec. 5th), and Dr. W. A. Potts (12th). Tickets can be obtained from the Secretary, N.U.T., and from Miss Olga Nethersole, 12, Stratford-place, London, W. 1.

A series of four lectures will be given at the Royal Society of Arts on Monday, Nov. 5th, and following Mondays, at 6 P.M., by Sir Henry Gauvain and Dr. C. W. Saleeby. The title of the series is Sunlight and Health. Tickets, 5*s.* for the course, or 1*s.* 6*d.* a single lecture, may be obtained from Miss Olga Nethersole, as above, or from the Secretary, Royal Society of Arts, John-street, Adelphi, W.C.2.

Fellowship of Medicine and Post-Graduate Medical Association.—A series of courses will be given during November in general and special subjects. From Nov. 5th to 17th a short course in general medicine and surgery will be given at the Royal Northern Hospital, with which will be associated the Central London Ophthalmic Hospital, the North-Eastern Fever Hospital, and the Royal Chest Hospital. The course will include demonstrations in the various departments from 10.30 A.M. each day. There will be a course in gynæcology at the Chelsea Hospital for Women from Nov. 5th to 30th at which lectures by members of the staff supplemented by demonstrations in the out-patient department and operations in the theatre will be given each day. Also from Nov. 5th to 30th the Maudsley Hospital have arranged a course of lectures and clinical demonstrations on some aspect of psychological medicine. The lectures will take place each afternoon. A course of lectures and clinical demonstrations in venereal diseases will be given in the wards and out-patient departments at the London Lock Hospitals from Nov. 5th to 29th, and from Nov. 12th to Dec. 6th, a series of 5 o'clock lectures on Gastro-intestinal, Respiratory, Genito-urinary and Skin Diseases of Children will be given at the Children's Clinic, Western General Dispensary. A practical course in ophthalmology will be given at the Royal Westminster Ophthalmic Hospital from Nov. 19th to Dec. 15th. There will be clinical instruction every afternoon from 2 P.M., and in addition a practical fundus class and special demonstrations in medical ophthalmology and methods of examination three times a week at 10 A.M. Further particulars and copies of the syllabus of any of the foregoing courses will be forwarded on application to the secretary to the Fellowship of Medicine, at 1, Wimpole-street, W. 1. The next fortnight's course in general medicine and surgery will be held from Dec. 3rd to 15th at the Hampstead General Hospital in association with the Hospital for Epilepsy and Paralysis, the North-Western Fever Hospital, and the Paddington Green Children's Hospital, of which further particulars will be given later.

Messrs. William Heinemann (Medical Books), Ltd., announce the forthcoming publication of "Psycho-Analysts Analysed," by Dr. P. McBride, with an introduction by Sir Bryan Donkin, and of the "Medical Year Book, 1924," which will be ready in November.

London Hospital.—The Catherine Gladstone Home at Mitcham has been brought up to date and redecorated by the "Marie Celeste" Samaritan Society, who will maintain and manage it as an annexe of the London Hospital. The opening ceremony will be performed by the Minister of Health at 3 P.M. on Nov. 19th, when the premises and the new ambulance which the committee has had specially built for the use of "annexe" patients of the London Hospital will be open to inspection.

Medical Women's Federation.—The Council of the Federation held its autumn meeting at Birmingham on Oct. 19th and 20th, in a room in the Medical Institute lent for the occasion. Lady Barrett, President of the Federation, was in the chair. The hon. treasurer announced that 164 new members had joined during the year and that the membership of the Federation now stood at well over 800. Arising out of the minutes of the last meeting was the report that inequality of payment of men and women medical officers at the Post Office still continued, and also that owing to protests made on this account by the Federation and the B.M.A. further appointments of medical women had been made without previous advertisement in the medical papers. It was resolved to write to the Postmaster-General calling his attention to the fact that this was contrary to the public interest, and it was further decided to take steps to impress upon newly qualified practitioners the importance of the principle of "equal pay for equal work" as applied to medical men and women. Among the business before the Council were the reports of the various subcommittees. The report of the subcommittee on venereal disease dealt with the traffic in women and children and with the Trevethin Report. It stated also that there was undoubted need of more medical women in the work of combating venereal disease, but that there was scarcity at present of medical women possessing special qualifications for this work. Several cases of underpayment were considered and dealt with. The question of the rate of payment of assistants in general practice came up for discussion in connexion with a letter from a young practitioner who had found herself obliged to accept an assistantship at very low remuneration, and who asked why the B.M.A. fixed what seemed a very high minimum for public health posts and had apparently fixed none at all for the post of assistants in general practice. It was pointed out that the value of the latter posts lay largely in the experience they afforded or in the prospects they offered, while junior public health posts were not infrequently "blind alleys." The general opinion was that young women practitioners would be wise to apply for posts of assistants to general practitioners more frequently than they did, and that these posts would be useful as a preliminary to public health work as well as to general practice. The opinion was also expressed that there was a considerable demand for women in general practice, and that many openings were still to be found unappropriated throughout the country.

The visit of the council members to Birmingham was not wholly devoted to business meetings, as a committee of the Birmingham and District Medical Women's Association—the local branch of the Federation—had provided a varied programme. On Oct. 18th a dinner was held at the Midland Hotel, at which 100 medical women and women medical students were present. Short speeches were given by Dr. Rose Molloy, who presided, Lady Barrett, Miss Frances Ivens, Dr. Mary Sturge, and Dr. Mabel Ramsay. Dr. Ramsay, who is the representative of the Federation on the B.M.A. Insurance Acts Committee and had taken an active part that day in the important meeting held in London, explained the reasons for the decisions there arrived at, and urged all women panel practitioners to support the policy adopted by the B.M.A. and to send in their resignations when demanded. She considered the conflict was between the medical profession and the approved societies, not between the profession and the Government. It was due to the determination of the approved societies to obtain greater control of the panel doctors, and this, if it came about, would be detrimental both to doctors and patients.

On the evening of Oct. 19th a reception was held at which guests of both sexes, including many prominent medical men and their wives, were present. A play written for the occasion, a skit on dreams and psycho-analysis, was acted, and gave much amusement. On the 20th visits were paid to the children's hospital and to the Carnegie welfare centre.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY, Burlington House, Piccadilly, W.

Thursday, Nov. 8th.—4.30 p.m.

Papers to be read : A. S. Parkes : Studies on the Sex-ratio and Related Phenomena ; Fœtal Retrogression in Mice. (Communicated by Dr. F. H. A. Marshall.) R. A. Fisher : The Influence of Rainfall on the Yield of Wheat. (Communicated by Sir John Russell.)

Paper to be read in Title only : D. Thursby-Pelham : The Placentation of Hyrax Capensis. (Communicated by Prof. J. S. Gardiner.)

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Tuesday, Nov. 6th.

ORTHOPÆDICS : at 5.30 p.m. (Cases at 5 p.m.)

Cases :

Mr. Laming Evans : Congenital Dislocation of Head of Radius.

Other cases will be shown.

PATHOLOGY : at 8.30 p.m., *at the Laboratory of the Imperial Cancer Research Fund, Queen-square, W.C. 1.*

Communications :

Dr. G. M. Findlay : Histopathology of Manganese Intoxication.

Dr. W. Cramer : Pathological Lesions of Tryptophane Deficiency.

Dr. J. A. Murray : Further Observations on Multiple Primary Cancer.

Demonstrations :

Mr. A. M. Begg : Mucor Granuloma of the Mouse.

Mr. A. H. Drew : Activation of Growth of Adult Tissues in Vitro.

Wednesday, Nov. 7th.

SURGERY : at 5.30 p.m.

Presidential Address :

Mr. Cyril A. R. Nitch : Cystic Pneumatosis of the Intestinal Tract.

Thursday, Nov. 8th.

NEUROLOGY : at 8.30 p.m.

Paper :

Dr. W. J. Adie : Pyknolepsy, a Form of Epilepsy in Children with a Good Prognosis.

Friday, Nov. 9th.

CLINICAL : at 5.30 p.m. (Cases at 5 p.m.)

Cases will be shown.

OPHTHALMOLOGY : at 8.30 p.m. (Cases at 8 p.m.)

Papers :

Mr. Valentine : A Pair of Diving Spectacles.

Mr. Lindsay Rea : A Preliminary Report on the Treatment of Interstitial Keratitis.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.

Tuesday, Nov. 6th.—5 p.m., FitzPatrick Lecture : Dr. C. J. Singer : The History of Anatomy.

Thursday.—5 p.m., Second Part of FitzPatrick Lecture.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

Thursday, Nov. 8th.—5 p.m., The Bradshaw Lecture : Mr. Walter G. Spencer : Melanosis (Melanin, Melanoma, Melanotic Cancer).

UNIVERSITY OF LONDON ADVANCED LECTURES IN SURGERY.

Thursday, Nov. 8th.—(At Guy's Hospital Medical School.) 5.30 p.m., Prof. E. W. Hey Groves : The Treatment of Injuries of the Long Bones produced by Accident or Disease.

Friday.—5.30 p.m., Second Lecture.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

Monday, Nov. 5th.—10 a.m., Mr. Maingot : Surgical Pathology. 12 noon, Mr. Simmonds : Applied Anatomy. 2.30 p.m., Mr. Addison : Surgical Wards.

Tuesday.—10.30 a.m., Dr. Paterson : Medical Wards. 12 noon, Dr. Burrell : Chest Cases. 2 p.m., Mr. Sinclair : Surgical Out-patients.

Wednesday.—10 a.m., Dr. Saunders : Medical Diseases of Children. 12.15 p.m., Dr. Burnford : Medical Pathology. 2.30 p.m., Mr. Armour : Surgical Wards.

Thursday.—12 noon, Mr. Simmonds : Demonstration of Fractures. 2 p.m., Mr. MacDonald : Genito-Urinary Dept. 2 p.m., Mr. Bishop Harman : Eye Dept.

Friday.—10 a.m., Dr. Drummond Robinson : Gynæcological Operations. 12 noon, Mr. Endean : Venereal Diseases. 2 p.m., Mr. Banks-Davis : Throat, Nose, and Ear Dept.

Saturday.—9.30 a.m., Dr. Burnford : Bacterial Therapy Dept. 10 a.m., Dr. Saunders : Medical Diseases of Children. 10 a.m., Mr. Banks-Davis : Operations on Throat, Nose, and Ear.

Daily, 10 a.m. to 6 p.m., Saturdays, 10 a.m. to 1 p.m., In-patients, Out-patients, Operations, Special Departments.

ST. JOHN'S HOSPITAL, 49, Leicester-square, W.C.

Tuesday, Nov. 6th.—5 p.m., Dr. S. E. Dore : Psoriasis.

Thursday.—5 p.m., Dr. M. G. Hannay : Erythemata.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE : October–November, 1923.

Clinical Lectures and Demonstrations.

Monday, Nov. 5th.—2 p.m., Out-patient Clinic : Dr. Hinds Howell. 3.30 p.m., Epilepsy : Dr. Aldren Turner.

Tuesday, Nov. 6th.—2 p.m., Out-patient Clinic : Dr. Grainger Stewart. 3.30 p.m., Disorders of Sensation and their Significance : Dr. Hinds Howell.

Thursday, Nov. 8th.—2 p.m., Out-patient Clinic : Dr. Kinnier Wilson. 3.30 p.m., Pituitary Disorders : Dr. Grainger Stewart.

Friday, Nov. 9th.—2 p.m., Out-patient Clinic : Dr. Gordon Holmes. 3.30 p.m., Surgery of Cerebral Tumours : Mr. Sargent.

Course of Lectures and Demonstrations on Neuro-Pathology.

Monday, Nov. 5th.—12 noon, Pathology of the Neuron, I. : Dr. Godwin Greenfield.

A Course of Lectures on the Anatomy and Physiology of the Nervous System commenced on Oct. 16th.

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 a.m., or at such other times as may be announced.

The fee for the Course, including Pathology, is £5 5*s*. The fee for the Anatomy and Physiology Lectures is £3 3*s*. If taken in conjunction with the Clinical and Pathological Courses, an inclusive fee of £7 7*s*. will be charged. Any part of the Course may be taken separately. Special arrangements will be made for those unable to take the whole Course. Fees should be paid to the Secretary of the Hospital at the Office on entering for the Course.

C. M. Hinds Howell, Dean of Medical School.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

Thursday, Nov. 8th.—4 p.m., Mr. Fairbank : The Treatment of Spastic Paralysis.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.

Wednesday, Nov. 7th.—4 p.m., Dr. W. A. Bullough : Problems of Health Service in Rural Districts.

THE PEOPLE'S LEAGUE OF HEALTH, 12, Stratford-place, Oxford-street, W.

Eight Lectures on the Mind and What We Ought to Know About It, at Hamilton House, Mabledon-place, W.C.

Thursday, Nov. 8th.—6 p.m., Second Lecture, Dr. R. H. Cole : Sensation, Perception, Ideation, and Attention.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE CLINIC.

Tuesday, Nov. 6th.—4.15 p.m., Dr. F. H. Westmacott : Chronic Catarrh of the Upper Air Passages.

Friday.—4.15 p.m., Dr. T. H. Oliver : Physiology and Pathology of Diabetes Mellitus.

ANCOATS HOSPITAL.

(Special Course on Surgical Tuberculosis.)

Thursday, Nov. 8th.—4.30 p.m., Mr. H. Platt : Tuberculosis of the Bone.

LIVERPOOL UNIVERSITY CLINICAL SCHOOL.

(At 3.30 p.m. each day.)

Monday, Nov. 5th.—(At the Children's Hospital.) Dr. Murray Bligh.

Tuesday.—(At the Southern Hospital.) Mr. Armour : Injuries and Diseases in the Neighbourhood of the Hip.

Wednesday.—(At the Northern Hospital.) Dr. Pemberton and Dr. Cunningham : Renal Inadequacy Methods of Determination.

Thursday.—(At the Stanley Hospital.) Mr. F. S. H. Heaney : The Chronic Abdomen.

Friday.—(At the Royal Infirmary.) Dr. Roberts : Modern Radiology.

UNIVERSITY OF BRISTOL POST-GRADUATE DEMONSTRATIONS.

Wednesday, Nov. 7th.—(At Swindon), Dr. R. A. Rendle Short : Diagnosis and Treatment of Common Gastric Disorders.

Nov. 9th.—(At Boscombe), Dr. A. L. Flemming : Difficulties in Anæsthesia.

Appointments.

Bayley, E., M.D. Lond., F.R.C.S. Eng., has been appointed Medical Officer to the Eastern Telegraph Company.

Davies, W. L. G., Chief School Medical Officer for Carmarthenshire.

Sowden, G., M.D. Brux., D.P.H., Barrister-at-Law, Medical Officer of Health for the Metropolitan Borough of St. Pancras.

King's College Hospital : Roberts, O. W., M.B., B.S., Senior Casualty Officer ; Connan, P., M.R.C.S., L.R.C.P. Lond., Second Casualty Officer ; Cave, E. H. P., M.R.C.S., L.R.C.P. Lond., House Anæsthetist ; Osborn, H. A., B.M., B.Ch., Resident Assistant Clinical Pathologist ; Sheldon, W. P. H., M.R.C.S., L.R.C.P. Lond., and Livingstone, J. L., M.B., B.S., House Physicians ; Snell, N. W., M.R.C.S., L.R.C.P. Lond., House Physician and Surgeon to Ophthalmic Department ; Kohnstam, G. L., M.R.C.S., L.R.C.P. Lond., Acheson, P. M., M.R.C.S., L.R.C.P. Lond., and Brockington, F., M.R.C.S., L.R.C.P. Lond., House Surgeons ; Edwards, H. C., M.R.C.S., L.R.C.P. Lond., House Surgeon to the Urological Dept. and Asst. House Anæsthetist; Collins, F. M., M.R.C.S., L.R.C.P. Lond., House Surgeon to Orthopædic Dept. and Third Casualty Officer; Saunders, R. M., M.B., Ch.B., Obstetric House Surgeon; Nicholson-Smith, E. M., M.R.C.S., L.R.C.P. Lond., House Surgeon to Aural and Throat Depts.

Vacancies.

For further information refer to the advertisement columns.

Barrow-in-Furness, North Lonsdale Hospital.—H.S. £225.

Bath Royal United Hospital.—Asst. H.S. £150.

Benenden, Kent, National Sanatorium.—Res. Asst. M.O. £275.

Birkenhead Borough Hospital.—Sen. and Jun. H.S.'s. £200 and £120 respectively.

Bolton Education Committee.—Ophth. S. 3 guineas per session.

Bristol General Hospital.—Hon. Asst. S.

Bristol Royal Infirmary.—Hon. Asst. Dental S.

British Honduras.—Asst. M.O. $2430.

Charing Cross Hospital Medical School.—Chemist to Bio-chemical Dept. £500.

Dundee Royal Infirmary.—Hon. Asst. Vist. Phys.

Eastbourne, Princess Alice Memorial Hospital.—Hon. Ophth S.

Elizabeth Garrett Anderson Hospital, Euston-road, N.W.—H.P., Obstet. Asst., and Two H.S.'s. Each £50.

Fulham Parish Infirmary, St. Dunstan's-road, Hammersmith, W.—Third Asst. M.O. £250.

Great Yarmouth Hospital.—H.S. £150.

Hospital for Epilepsy and Paralysis, Maida Vale, W.—Hon. Dentist.

Hospital for Sick Children, Great Ormond-street, W.C.—Med. Reg. and Pathologist. £300.

Islington Dispensary, 303, *Upper-street, N.*—Sen. and Asst. R.M.O.'s. £300 and £220 respectively.

Leamington Spa, Warneford, &c., General Hospital.—R.H.S. £150.

Leeds Public Dispensary.—Sen. Res. M.O. £200. Hon. Radiol. and Hon. Dent. Surg.

London Jewish Hospital, Stepney Green, E.—Res. M.O. and Jun. Res. M.O. £150 and £100 respectively.

Lowestoft, St. Luke's Hospital.—Jun. Asst. M.O. £500.

Manchester City.—M.O. £620 19*s.* 9*d.*

Manchester, Monsall Fever Hospital.—Jun. Med. Asst. £405 6*s.*

Margate, Princess Mary's Hospital for Children, Cliftonville.—Jun. Asst. M.O. £500.

Poplar Hospital for Accidents, East India Dock-road, E.—Sen. Res. O. £275.

Portsmouth Royal Hospital.—H.S. £150.

Queen Charlotte's Lying-in Hospital, Marylebone-road, N.W.—Two Asst. Res. M.O.'s. £80.

Royal Northern Hospital, Holloway, N.—Res. M.O. £250. Cas. O. £125. Also Two H.S.'s. Each £75.

St. Mary's Hospital for Women and Children, Plaistow, E.—Asst. Res. M.O. £130.

St. Peter's Hospital, Henrietta-street, W.C.—Asst. S.

Salisbury Municipality, Rhodesia.—M.O.H. £600.

Sanitary Inspectors' Examination Board.—Examiners.

Sheffield Royal Infirmary.—Ophth. H.S. £100.

West London Hospital, Hammersmith-road, W.—Hon. Asst. S. to Throat, Nose and Ear Dept.

Willesden Municipal Hospital for Infectious Diseases, Brentfield-road, Neasden, N.W.—R.M.O. £367 12*s.*

The Chief Inspector of Factories, Home Office, London, S.W., announces a vacant appointment at Lyme Regis, Dorset.

Births, Marriages, and Deaths.

BIRTHS.

Fernandez.—On Oct. 26th, at a nursing home, to Christine (née Mayo), wife of T. Fernandez, M.R.C.S., L.R.C.P., M.A. Cantab., of 79, Sutton Court-road, Chiswick, W. 4, the gift of a son.

Fry.—On Oct. 25th, to Dr. Gladys Miall-Smith, of Welwyn Garden City, the wife of Dr. H. J. B. Fry—a son.

Gordon.—On Oct. 21st, at Largo House, Largo, the wife of Captain S. Gordon, I.M.S., of a daughter (stillborn).

MARRIAGES.

Kerr-Pringle—Hunt.—On Oct. 24th, at Cople, Bedfordshire, George Loraine Kerr-Pringle, M.C., M.D. Edin., to Dorothy Isabel, only daughter of the late Alfred Foster Gradon, Indian Woods and Forests, and widow of Seward Hunt, of Alta Gracia, Rep. Argentina.

Norris—Rathouse.—On Oct. 26th, at Poplar, D. C. Norris, M.B., B.S., F.R.C.S., &c., late Senior Resident Officer, Poplar Hospital for Accidents, to Hélène Rathouse, M.D. Paris and Geneva, L.S.A. London.

DEATHS.

Gostling.—On Oct. 25th, at Sunnyside, Winchester-road, Worthing, Thomas Preston Gostling, M.R.C.S., L.R.C.P., L.S.A., O.B.E.

Lane Notter.—On Oct. 24th, at a nursing home in Southampton, Colonel James Lane Notter, late A.M.S., aged 80.

Tristan.—On Oct. 25th, at Retford, Richard Joseph Tristan, L.R.C.S., L.R.C.P. Edin., of Retford.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE ROYAL ARMY MEDICAL CORPS AND ITS WORK.

The Inaugural Address delivered before the Royal Medical Society, Edinburgh,

By Sir William Leishman, K.C.M.G.,

DIRECTOR-GENERAL, ARMY MEDICAL SERVICE.

Sir William Leishman said that he would not talk about the work of the R.A.M.C. in war-time as many of his audience had had considerable experience of that. He divided his address into three parts, beginning with a short account of the stages of service and of the environment and atmosphere of the work, going on to tell of its nature and varieties, and concluding with some of the results obtained.

The Pilgrim's Progress.

In the first part, the speaker said, he had to describe a sort of Pilgrim's Progress. Lieut. "Christian," having passed his examination, was sent to the Army Medical College, where, in addition to the pleasures of comradeship and community of interest which mess life gives, he enjoyed the great advantage of meeting older officers, travelled and experienced both in war and in sport. Here his knowledge was supplemented with the kind of information especially required for military work. Having completed this course, Lieut. "Christian" passes out to the R.A.M.C. depôt, where he is instructed in drill, riding, field work, and similar matters of a military and executive nature. It is at the depôt that he first comes in touch with the men of the Corps. After this he is posted for service and comes into association with other branches of the service. He begins with home service; then comes his foreign service, the attractions of which are many, bringing with it the delights of travel, of widened interests, of intimate friendships and opportunities for sport and games which home life cannot give. He experiences the delight of leave on full pay and free from all anxiety as to the effect on his practice—a thing the struggling young civil practitioner dare not dream about for years. If he goes sick he is treated most generously by the Corps. After seven and a half years' service Captain "Christian," as he now is (he attains that rank, all being well, after three years' service), comes home for his senior course. If he pass the subsequent examination above a certain standard, he is given the opportunity to specialise in any one of certain subjects. In the average case there follows for a period of years alternate home and foreign service, and, after some 20 to 25 years of service, Lieut. "Christian" reaches the exalted rank of Lieut.-Colonel. After that promotion is by selection.

Specialisation in the R.A.M.C.

Going on to speak of the work of the R.A.M.C., Sir William Leishman said that, in spite of popular belief, it was no easier than civil work. Just as much knowledge was required, and more. What they wanted was a really good general practitioner, efficiently trained and self-reliant. The Corps offered a wide field of specialisation in almost every branch of medicine, including pathology, hygiene, general medicine and surgery, dermatology, venereal disease, ophthalmology, radiology, and even midwifery, gynæcology, and pediatrics, for soldiers were sometimes married and had children. The conditions were admirable. They dealt with subjects of high physical efficiency, and it was possible to have a man's complete medical history from the day he joined to when he was discharged. In addition to ordinary medical work and war training, there was work such as recruiting, offering an interesting field to anyone keen on vital standards, anthropology, and kindred subjects; physical training with its associated problems of fatigue, diet, &c.; and sanitation, which, especially abroad, gives great opportunities for epidemiological and kindred work.

The Value of Prophylactic Treatment in Enteric Fever.

Speaking of results, Sir William Leishman said that he would not give a series of statistics. He would content himself in that direction by mentioning the fact that in the Boer War there were more deaths from enteric fever than there were cases of it in the late war. This he attributed in large part to the use of the prophylactic T.A.B. vaccine introduced by Sir Almroth Wright. The army was really the birthplace of hygiene, and Parkes was its father. In connexion with pathology and bacteriology, he mentioned the work of Wright, Harrison, Harvey, Cummins, and others. Lewis, Bruce, and Simpson, among many others, had contributed greatly to our knowledge of tropical diseases. In medicine and surgery the names were too numerous to mention. Every branch of the two subjects could be and was being studied.

Sir William Leishman concluded by speaking of the new and flourishing army dental department and of the ambitious task it had undertaken of examining every tooth in the army. It would, he said, be interesting to see what effect this had on the incidence of those diseases in which caries and pyorrhœa alveolaris are supposed to be important ætiological factors.

STIMULANTS OF GROWTH.

At the first social evening of the session, on Oct. 30th, Prof. Gowland Hopkins, F.R.S., Cambridge, delivered an address on this subject to the Royal Society of Medicine. Of all the attributes of life in whatever form, growth, he said, was the most characteristic, but the question of growth had so many aspects that he was compelled to confine his remarks to only one of these—namely, is growth a process that goes on spontaneously, or does it need a stimulus, just as a muscle or nerve cell needs a stimulus to make it perform its function? The whole animal body was under the influence of stimuli, and growth of the body was controlled by the action of the internal secretions. He showed some interesting lantern slides to illustrate the rôle played by the pituitary body in controlling development. But the conditions governing growth of the body were too complex to illustrate the phenomena he wished to consider, therefore it was necessary to deal with observations made on unicellular organisms. In protozoa the function of growth dominated all other functions, yet the distinction between the growth of these organisms and that of complex animal tissues was mainly superficial—one characteristic of both was that when the individual cell reached a certain size it divided. What was the nature of the substances which caused the cell to grow and divide? It was found that artificial parthogenesis always required a stimulus of some sort. What was this stimulus? Was it something which wakened the dormant activity of the growth processes, having a "trigger action," or was it "building material"? The smaller the amount of the material required, the more likely was it to be a stimulant. There were other substances, too, which acted as catalysts, whose presence was necessary to the continuation of growth.

In considering the growth of bacteria, the lecturer said that the more saprophytic or parasitic the organism the more stimulus was required for multiplication, but the amount of the substance necessary to growth was so infinitesimal that, in his opinion, it could not be building material, but must be a stimulant. What was this substance? If you isolated a single protozoon and transferred it to a medium of too large a bulk it would not grow. Starting with one individual, the number of cells by fission would be inversely proportional to the amount of medium. Were two cells put into the same amount of medium, the number produced by fission would be 20 times greater than in the first case, when you started with one cell. These proved facts seemed to support the theory that the cell-nucleus, on dividing, poured a growth-catalyst into the culture-medium; the less medium, the greater the concentration of the catalyst, hence the more abundant the growth. Turning to the animal body, Prof. Hopkins pointed out that though the adult animal as a whole had ceased to grow, the cells of its tissues transferred to a suitable medium did not cease to grow, and here, he said, we were touching on the great problem of cancer. It was extremely unfair, he added, to say that nothing had been done in this country in the investigation of cancer. The effect of vitamins on growth was that of a stimulus, for experiments showed that the addition of the minutest quantity (1 mg. or less per day) to the food of vitamin-deprived rats produced a remarkable and immediate growth. Finally, he pointed out, although the pituitary gland was a tissue highly specialised for the general control of growth, any living cell of itself could supply stimulants for growth. When cells were living in community, one cell could stimulate the other to some extent.

In moving a vote of thanks, Prof. E. H. Starling paid a tribute to Prof. Hopkins's power of finding among the thickets of ignorance which surround us some path to knowledge which others had passed by unheedingly, and instanced his recognition of vitamins in growth as a case in point. He expressed his gratitude to the lecturer, not so much for what he had given, but for the keen sense he aroused of something that was about to come. Previously to the address, Sir William Hale-White, the President, presented the Society's gold medal to Prof. Hopkins.

A WORCESTERSHIRE HOME FOR MENTAL DEFECTIVES.

The sixth annual report of the Besford Court Catholic Mental Welfare Hospital for Children discusses the general problem of the treatment of the mentally defective child and shows a full appreciation of the requirements for its solution. Conventional training in the "three R's" is regarded as unimportant, except for reading, the main objects being to educate such powers as the child possesses and to eliminate that emotional instability which makes the high-grade moron an expense to the community when he reaches adult life. The economy axe has made a dead letter of the 1914 Act, which should compel local authorities to provide suitable education for defective children, and the report points out the futility of training these children in ordinary schools. The Besford Hospital is certified by the Board of Education, the Board of Control, and the Home Office, and receives grants from various authorities, a fourth part of the expenses being derived from special appeals. There is no accommodation for girls, and it is not found possible to accept the lower grades of mental defectives; only those are admitted who can reasonably be expected to be made at least partly self-supporting in adult life. With these unavoidable limitations the institution carries out a work of public benefit, and the modern and enlightened methods indicated in the report should add to our knowledge of how to handle these difficult cases.

A DIRECTORY OF PRACTISING MIDWIVES AND MATERNITY NURSES.

A classified directory has been issued by the Scientific Press, Ltd., for the convenience of the medical profession and the public. It is divided into the following sections: (1) Certified midwives practising alone; (2) certified midwives practising with doctors; (3) maternity nurses. In regard to sections (1) and (3), it is emphasised that under the Midwives Act it is a punishable offence for any woman not certified under the Act to attend another woman in labour "habitually and for gain" except under the direction of a registered medical practitioner. Each section is arranged under the headings London and County Suburbs, Provincial, Wales, Scotland, Ireland, and Channel Islands, and the names are given in alphabetical order with addresses.

EXEMPTIONS TO SOUTH AFRICAN TAX ON PATENT MEDICINES.

A notice in the South African Union *Gazette* of Oct. 5th states that for the purposes of the Customs and Excise Duties Amendment Act of 1923 the term "patent or proprietary medicines" shall not be deemed to include "the under-mentioned household remedies, whether sold under a particular trade mark or labelled with a recommendation or not," namely "arnica, camphorated oil, carbolic oil, carbolic ointment, castor oil, cod-liver oil, dill water, embrocation, Epsom salts, eucalyptus oil, glycerine, Gregory's powder, gripe water, Hoffman's anodyne, ipecacuanha wine, liquorice powder, malt extract, malt extract and cod-liver oil, medicinal paraffin, quinine—ammoniated tincture of, soothing powders, teething powders, zinc ointment."

A BOOK OF REFERENCE.

The Annual Charities Register and Digest. 1922 (London: Longmans, Green & Co., pp. 554, 7*s.* 6*d.*).—This year-book, now in its thirty-second edition, is so well known that mention of its contents is becoming superfluous. The volume opens with the customary review of the finances of the charitable institutions of London and its neighbourhood, and contains the usual detailed and up-to-date sections devoted to relief in affliction, sickness, and distress and to reformatory relief, obtainable in or about the capital. The miscellaneous section includes information on social and physical improvement, employment, emigration, and protection of human and animal life and of the helpless, and appended chapters deal with benevolent institutions, trade and friendly societies, registry offices, savings banks, and employment exchanges.

"THE WORLD'S CHILDREN."

An interesting feature of the first number of the fourth volume of this quarterly publication (published at 30, Mortimer-street, London, W. 1, 1*s.*) is a symposium by educationists on "Next Steps in Education," which gives a number of representative views as to the paths into which educational progress should be directed at the present time. The activities of the Save the Children Fund are set out in detail. There is a delightful article by Sir Robert Baden-Powell on Climbing as Education—he suggests an obstacle track of indoor and outdoor furniture such as chairs, boxes, wheel-barrows, garden seats for children of three, leading on to tree, rock, and mountain climbing for older children. The educational value of a child's natural instinct for climbing is enormous, for besides developing muscle climbing stimulates the association areas of the brain and teaches self-control and nice calculation. Major Leonard Darwin's article on a Child's Rights is more controversial. While not disputing the right of a child to a good home, he argues that the alternatives of complete removal from an unusually bad home and of supplementing home supplies generally results in an increased output from the bad or indifferent home with more suffering for future generations.

Some Ideas
ON
OUR SUCCESSORS.

The Presidential Address to the Sheffield Medico-Chirurgical Society, delivered on Oct. 11th, 1923,

BY A. E. NAISH, M.B. CAMB., F.R.C.P. LOND.,
LECTURER ON MEDICINE, UNIVERSITY OF SHEFFIELD;
PHYSICIAN, SHEFFIELD ROYAL HOSPITAL.

FOR a moment let us take a bird's-eye view of the hanges which have taken place during the medical fe of some of us. Much has been said lately in the aily papers and elsewhere of the specialisation that taking place to-day and the dangers that it brings its train. Quite as remarkable and significant to y mind is the tendency to unification. When I was student chemistry was chemistry and physics hysics in very much the same way as the East nd West of Kipling's famous song, but now the henomena of adsorption, surface-tension, colloidal ates, ionisation, &c., have come in to break down e barrier, and the modern worker in most branches chemistry finds himself more and more dependent physical laws and formulæ. In my student days e subjects of electricity and light did not seem to ave much to do with one another, but now we nceive ourselves to be surrounded by a medium ther) in which vibrations with every gradation of ave-length are taking place, and we for the most art are quite unconscious of their presence, although dowed with one sense-organ capable of responding a few of these vibrations if they come within a tiny nge of wave-length. Electricity, X rays, wireless, ght, &c., we believe to be of essentially the same ature. I need not point out the close connexion etween electricity and chemistry. The ordinary emical battery and the phenomenon of electrolating let us have an inkling of this long ago, and e modern theory of the atom bids fair to make both ne. Thus physics may be said to be widening out nd swallowing up what were previously separate iences. I think there is a special significance to us human investigators in this unification of all henomena. Perhaps I can put my point of view est by means of an analogy from the history of ligion. When human beings believe in a large umber of separate gods, it is not long before they egin to regard each one with some condescension, be bargained with, tricked, petted, and cajoled. ith the advent of monotheism, the grandeur of the bject of veneration tends to give man a proper sense f humility. The greater the unification, the larger nd more unexceptional the generalisations, the more an stands in his proper relation as servant to truth.

CHANGES IN OUR VIEWS OF DISEASE.

Turning to more immediately medical subjects, lo we see there any sign of this process of unification? f one were asked what is the most significant change hich has taken place in our time I think the answer ight be that it is not this or that discovery in acteriology, this or that improvement in surgical kill, this or that new arsenical product or internal land product or vaccine, but the change which is aking place in our views of disease. In the old days e regarded everything in the light of the anatomical hange which it produced in an organ. We labelled ur disease: cirrhosis of the liver, valvular disease f the heart, granular kidney, and as long as we knew he microscopical appearances thoroughly were content hat we knew all about it. I remember that when, me ten years ago, auricular fibrillation was first sed as a diagnostic term, many would ask, "What is s morbid anatomy?" and when the answer was It has none," would turn away with a pitying smile nd not trouble to inquire any further.

If one wants to find out about the habits and mode f life of primitive man there are two methods which can be employed. One is to examine the skulls and other bones that have been left after the ravages of time, any flints or other instruments that have been found in the same geological strata, any habitations or methods of burial of which traces have been left, and from these to construct the story. The second, and better, method is to find a primitive tribe still living, to go and live among its people and to become initiated if possible into all their customs and mysteries, such as has been done by Spencer and Gillen among the aborigines of Australia. This may be called the physiological method in contradistinction to the other or anatomical method. In our student days physiology was a science applicable to the healthy body; as soon as disease supervened one's curiosity was supposed to be satisfied by anatomy. It was, furthermore, a science based almost wholly on animal experiment.

How it Works.

To-day our curiosity is thoroughly aroused on the subject of how disease *works;* we want to take the lid off and see the changes occurring. Furthermore, a large and increasing amount of physiological research is being done on the human body and even on the diseased human body. For determining the rate of the circulation we used to be dependent on deductions from animal experiment. Now more than one method is available for determining it directly from the human subject. We have the means of studying its variations from the normal in various diseases and determining how far the ill-effects are due to such variations. Such estimations are, of course, an essential preliminary to rational therapeutics.

Discoveries about the wonderful properties of the blood for the extremely rapid capture and release of oxygen and CO_2 at each end of the circulation, and the extraordinary mechanism for the provision of sufficient oxygen to the muscles over a wide range of need have been made largely through observations on the living human subject. The same may be said about our present knowledge of the constancy of the blood alkalinity reaction, so exact that a change too small to be detected by our most delicate tests is enough to cause a very obvious alteration in the rate of breathing.

Direct investigation on human beings is only in its infancy, yet we are already beginning to have a much clearer idea of disease processes. For instance, we are beginning to get a conception of the blood delicately balanced, in a state of unstable equilibrium, poised like an acrobat on a tight rope, pushed and pulled by a hundred different forces, swaying first a little to this side and then to that, but retaining a remarkable degree of stability. In disease we can register some of its dangerous swayings, and watch its return to equilibrium. As the "Devil on two sticks" was able to take off the roofs of the houses and see what was going on inside, so our successors will have a clear view of the complicated processes of health and disease. Some cynic or other will say that these successors of ours will no longer be men but machines. Already there is said to be an instrument which will register almost automatically the percentage of gases in the alveolar air, and foolproof sets for the testing of blood-sugar are advertised. Will not the patient of the future enter a kind of Chicago sausage factory, be whirled from one test to another, and be presented at the end with a set of graphs or even one composite graph representing his bill of health, and a table of instructions which will bring him back to, or keep him in, the narrow path of physiological righteousness? Nay, will he not, for the good of the community, be forced willy-nilly to undergo the machines every three or four years? The arch cynic might even suggest that as we have ceased to eliminate the unfit in other ways, the machines might be a very good substitute. Ribald persons are even now heard to suggest that the extraordinarily good surgical statistics at some clinics are due to the preliminary weeding by the tests.

Does not the mind falter and hesitate to go forward to such mechanical triumphs ? Should not we rather shoulder our illnesses than be slaves to such a mechanistic life ? Samuel Butler in his " Erewhon " pictured a people so much afraid of becoming slaves to their own machines that they abolished them by law, and it was a penal offence even to carry a watch. This is the eternal struggle. Look through history and you will see man constantly devising systems for the economy of time and effort, and constantly becoming entangled in his own rigid creations till some strong thinker or poet comes to release him. The way by which medicine will escape from the dominance of mechanics will perchance be through the altered emphasis that will be put on mental as compared to physical ailments.

The Fetish of the Healthy Body.

At the present time civilised man hardly seems to view in their right perspective the unhappy results of bad bodily and bad mental health. The healthy body has been made a fetish. The daily papers acclaim and exaggerate every slight advance in therapeutics, and paint horrible pictures of disease. They lead people on to think of their livers and hearts and kidneys, and to seek salvation through the extirpation of physical disease. We see the results in a hundred ways. The only son who has been examined again and again for tuberculosis, whose vests are too thick, and who has been stuffed with cod-liver oil and cream. The small " prep." school with its fussy head and matron, where the anxious parents send their supposed delicate boy. The tame doctor to minister to the needs of one family or even one person. The man with the slightly stiff knee surrounded by his clientèle of specialists, nurses, and masseurs. After all, this strong longing for health has been a natural thing in the world hitherto. When small-pox, typhus, cholera, plague, tuberculosis were great mysterious scourges, no wonder that a man wished above all things to have a healthy body.

Now, when one comes to think in broad outline one is struck by the fact that the greater part of human misery is mental, and that the part that bodily ill health plays in its production is over-emphasised. Physical pain and disability are not to be compared in their devastating effects to the mental plagues from which so many in a modern community suffer. So greatly does the unfortunate neurotic dread his mental disturbances that he will court physical pain and disease in an effort to escape from them. We live in a world of men and women potentially capable of far greater things than they actually accomplish, but hampered by the inharmonious or undeveloped working of their central nervous system. We all know the man who, perhaps possessed of fine intellectual qualities, is yet a burden to himself and an ever-widening circle of acquaintances, because he has never learnt to harmonise his conflicting instincts.

THE POWER WITHIN THE BRAIN.

I picture to myself the man of the future seeing far more clearly than we do the terrible waste involved when even one brain fails to realise its potentialities, and demanding of the parson, the doctor, and the schoolmaster that they shall mobilise their forces for the solution of the problem how to realise the best of which each brain is capable. Just where the boundaries between these three professions will be drawn in the future it is impossible to say. They are not likely to remain the same as hitherto. A medical man trained in the method of checking every stage of speculation by direct observation, soaked in the anatomy and physiology of the central nervous system and its development from humble beginnings, is capable of becoming of invaluable assistance in the development of better methods of education. By education I mean, of course, not any narrow school curriculum, but the whole process by which from infancy stimuli are applied to obtain a maximum development of brain function.

Consider, for instance, Head's analysis of cases showing lesions in the neighbourhood of the optic thalamus. Primitive sensations of pain, heat, a
cold released from the control of the cortex a
felt in an " all or nothing " manner, either intense
painful or not at all. Feelings of disagreeableness su
as from scratching the palm with the finger-nail,
from squeezing a part of the body, are imbued with
much more intense feeling of aversion on the affect
side, and even stimuli producing emotional sensatio
such as mournful music could not be borne by some
the patients because of a disagreeable sensation on t
affected side only. In this comparatively primitive p
of the brain, sensation or emotion is felt in an ov
powering " all or nothing " fashion. Thinking ov
this, we begin to understand how it is that waves
over-mastering emotion will sweep through a primiti
or uneducated throng ; how it is that the mo
unreasonable certain likes and dislikes are, the mo
intense and overwhelming and fundamental th
appear to their possessors. Head's analysis of lesio
of the cortex showed that no amount of destructi
would abolish crude sensation but only the power
comparison ; the sense of longer or shorter, hotter
colder, rounder or squarer, thinner or thicker, heavi
or lighter, and the comparative position of the lim
in space. We can see at once that such discriminati
sensation is at the basis of all comparison of one thi
with another, and therefore of all reasoning pow
There is no strong driving emotional sensation in t
cortex ; it is essentially a critical organ.

Emotion Harnessed to Intellect.

Putting together these observations on the cort
and basal nuclei we begin to understand how it
that strong emotions so readily accompany our mo
indiscriminative and ill-considered actions ; why it
that the critical and reasoning faculties seem so oft
to us hard and dry ; how difficult it is to get emotio
enthusiasm to irradiate reasonable conduct ; why
so often think in one way and act in another, in fa
these different layers of development are probably t
explanation of the mental conflict which is so distre
ing a feature of civilised life.

> " Give me the man that is not passion's slave, and I
> wear him in my heart's own core ; yea in my heart of heart

The theme underlying all Shakespeare's gre
tragedies was the pathos of great character over-bor
by an emotion. The truth appears to be that we ne
emotion as a driving power to carry us along to acti
and that the cortex or discriminative part does n
possess this of itself, but is dependent on borrowin
so to speak, from a more primitive part. By a proce
which is technically known as facilitation, or mo
popularly as habit, the emotion may be got to wo
more readily with discrimination, but if this connexi
is to be at all strong it must be started at a very ea
age. This linkage of the emotion with the intell
seems to me at the basis of all successful educati
The failure of the crammed boy to make a succe
in after life because his emotions have never be
harnessed to his intellect is an instance in point.
by means of early training we can in the majority
human beings make the emotions the servants a
stimulators of the intellect, we shall have no ne
to teach ; people will teach themselves ; misunde
standings and quarrels between individuals, which a
all really irrational, will largely disappear ; and men
conflicts will cease to be the scourge that they are
present. The necessity for this junction has, of cour
been long recognised by far-sighted individuals.
is what Emerson meant when he said, " Hitch yo
wagon to a star " ; and the process is known to psych
logists as sublimation. The medical man, howeve
with his observations on disease such as those by Hea
or his experiments on facilitation such as those
Sherrington, is laying a sound foundation for a scien
which will deal with education.

THE MEDICAL MAN OF THE FUTURE.

My imaginary medical man of the future will
largely engaged with this most important of
subjects. How far the process of sublimation can
effected in the mass of mankind by means of ea

aining is a matter which only the future can decide, ut the prize is so great that it is worth some seeking. am myself optimistic. The plasticity of the human rain is its most striking characteristic; it was evolved ecause it made man capable of fitting himself to any hange in his environment. The brain is now being sed for very different purposes from those for which was evolved. The importance of early beginnings not easily realised by the majority of men. We are pt to think of children in a sentimental, non-rational ay. But in most of us the force of public opinion ften acts like the proverbial snowball. Looking back n the past 15 or 20 years the altered attitude of people n the subject of infant welfare is amazing. I quote paragraph from a modern book—

> "The causes of the imperfections and ill-health of adult e are now being sought at their source—the mistakes in fancy. The helpless, innocent crying babe, once con- lered a by-product of obstetrics, has become the centre a sociological and medical movement such as the world s never known."

Mayhap in another 20 or 50 years the importance of -digging our mental foundations will be as widely cognised. What is needed as a preliminary to progress a fuller study of children with regard to their men- lities and the things which are attractive to them various ages, and the conducting of well-controlled periments in linking the steps of developing dis- imination, based on the guidance of these observa- ons. Educationists are attempting this, but I am sular enough to believe that medicals will in many ays do it much better. The clinician is trained on the dividual case, he is less influenced by the artificial les of the game; to him if the theory does not incide with the observation, so much the worse r the theory, it must either be patched or scrapped; is less likely to throw together masses of undigested atistics and draw erroneous conclusions from them; knows more at first-hand about the interaction of dily and mental health, and he has a better basis of atomy, physiology, and embryology to work from.

I quote from a book called "The Making of the estern Mind," a survey of European culture from e time of the Greeks up to the present day, written two literary men:—

> "Medicine is the best example of unquestioned progress e to science, and partly as a cause and partly as a result this we find medical men the most hopeful of the future d confident of their powers. Their science is the best pe of accurate and systematic knowledge applied to the od of man. It has the high merit of encouraging us to pect similar results in political, social, and economic atters and to take steps to secure them."

The Need of Efficient Training in Psychology.

If we are to take our part, and possibly the leading rt, in what may be the greatest movement in man's story it behoves us to be up and doing. The present ate of a medical man's training in psychology is little ort of scandalous. The really efficient general actitioner is a marvel in the development of his ychological sense, and one runs little risk of contra- ction in saying that the greater part of the good at he does is by its means. It is an extraordinary lvertisement for the benefit of direct learning from ture that a man without possibly a syllable of book ychology should yet be able to attain such skill. ut these are the gifted ones in the profession and even ey suffer through lack of scientific training, and pecially from an inability to generalise, so that the sults of their observations die with them. In order at the mass of the profession should participate d that these observations should be available as epping stones to higher things it is necessary that ere should be an educative substructure.

Psychology is a subject which is in vogue at esent, especially with the man in the street, and consequence there is a good deal of rubbish foisted to the public; but there is a true solid and rapid vance being made, and there is a special need for a tically trained profession to make it their own.

Whether or not we are called upon to take our share the right development of the growing mind, there is still a huge scope for medicine in the patching and mending of the adult mind. Our attitude towards neurotics in the past has been too much that of the priest and Levite; we diagnose the condition and then pass by on the other side with a shrug of the shoulders and the phrase: "It's only a neurosis. Let's go and look at some interesting organic disease."

My imaginary doctor of the future will reverse the process. With him it will be, "Oh, this is only an organic disease, just run him through the machines; but here's an interesting neurosis: did you ever meet with such a remarkable combination of phobias?" At present there is nearly always the feeling at the back of our minds that it is the patient's own fault that he is in this state of mind. Approaching him like this we are bound to make him feel humiliated. To destroy his self-respect is the very worst treatment for a neurotic; seven other devils worse than the first will enter him if we are successful. But we seldom are, because the patient's own defiance or negativism, as it is technically called, is aroused, and we find ourselves without influence. "That doctor didn't understand my complaint" is what is said as soon as our back is turned.

The French proverb—"To understand everything is to forgive everything"—may be considered as a prophecy that, in the future, a narrow morality will be superseded by a more truly scientific method of dealing with mental twists. Moral disapprobation—making people feel ashamed of acts which are not for the benefit of the community—is the strongest weapon which society has been able to wield hitherto for the coercion of the individual, but there are signs that it is now being regarded as not very well fitted to our needs, and, in many instances, as cruel and ineffectual; liable, in some cases, to lead to hypocrisy and subterfuge, in others to defiance and a sense of injustice. Medicals are particularly liable to be struck by the injustice of its action. They see an epileptic who in the normal course of his life is honest and law-abiding, but who for certain periods before or after a fit, or even independently of a fit, becomes a liar, a thief, or even a murderer. They see a person with heart disease, who has been placid and affectionate, become irritable, unruly, and impossible to live with. They see a dipsomaniac or sexual pervert in whose case there is a clear family history of the same disease. Application of one universal panacea of moral indignation reinforced by criminal proceedings leads largely to concealment and aggravation.

"Erewhon."

Samuel Butler in "Erewhon" satirises the indiscriminate application of such a crude remedy by making the inhabitants of that country reverse our own procedure with regard to physical and mental aberrations.

> "In that country if any man falls into ill-health, or catches any disorder, or fails bodily in any way before he is 70 years old, he is tried before a jury of his countrymen, and if convicted is held up to public scorn, and sentenced more or less severely as the case may be. There are subdivisions of illnesses into crimes and misdemeanours as with offences amongst ourselves—a man being punished very heavily for serious illness, while failure of eyes or hearing in one over 65, who has had good health hitherto, is dealt with by fine only, or imprisonment in default of payment. But if a man forges a cheque, or sets his house on fire, or robs with violence from the person, or does any other such things as are criminal in our own country, he is either taken to a hospital and tended most carefully at the public expense or if he is in good circumstances, he lets it be known to all his friends that he is suffering from a severe fit of immorality just as we do when we are ill, and they come and visit him with great solicitude, and inquire with interest how it all came about, what symptoms first showed themselves, and so forth—questions which he will answer with perfect unreserve; for bad conduct, though considered no less deplorable than illness with ourselves, and as unquestionably indicating something seriously wrong with the individual who misbehaves, is nevertheless held to be the result of either pre-natal or post-natal misfortune.
>
> "The fact that the Erewhonians attach none of that guilt to crime that they do to physical ailments, does not

> prevent the more selfish among them from neglecting a friend who has robbed a bank, for instance, till he has fully recovered; but it does prevent them from even thinking of treating criminals with that contemptuous tone which would seem to say, 'If I were you, I should be a better man than you are,' a tone which is held quite reasonable in regard to physical ailment. Hence, though they conceal ill-health by every cunning and hypocrisy and artifice which they can devise, they are quite open about the most flagrant mental disease, should they happen to exist, which to do the people justice is not often. Indeed, there are some who are, so to speak, spiritual valetudinarians, and who make themselves exceedingly ridiculous by their nervous supposition that they are wicked, while they are very tolerable people all the time.
>
> "They send for the Straightener at once whenever they have been guilty of anything seriously flagitious—often even if they think that they are on the point of committing it; and though his remedies are sometimes exceedingly painful, involving close confinement for weeks, and in some cases the most cruel physical tortures, I never heard of a reasonable Erewhonian refusing to do what his Straightener told him, any more than of a reasonable Englishman refusing to undergo even the most frightful operation, if his doctors told him it was necessary."

He thus makes fun of the doctor who refuses to deal with anything outside the physical sphere:—

> "I heard of one lady, who had the hardihood to confess that a furious outbreak of ill-humour and extravagant fancies for which she was seeking advice was possibly the result of indisposition. 'You should resist that,' said the Straightener in a kind but grave voice; 'we can do nothing for the bodies of our patients; such matters are beyond our province, and I desire that I may hear no further particulars.' The lady burst into tears, and promised faithfully that she would never be unwell again."

There is little doubt that medical men will have to be called in to take their part in questions involving moral conduct, and that their part will be that of investigation, and the choice of the most suitable remedies. Already in a few cities a considerable proportion of the juvenile offenders are referred by the magistrates to a medical man with special experience, in order that their mental calibre may be assessed, and appropriate treatment advised. In a few large prisons the medical officer is specially chosen to perform a similar function. Unfortunately, the paucity of the means of treatment at present available largely handicaps their efforts. The worst cases can be placed in an institution for the mentally defective; for the rest there is little else than the Borstal system. With the advent of a real and whole-hearted determination to deal scientifically with mental aberration the crude remedy of moral disapprobation will slowly disappear, and then our patients will no longer fear to expose their weaknesses in the early and incipient stages. The basis of truth underlying the Freudian theory appears to me to be dependent on this rough and harmful action of the moral conventions on the integration of the brain processes.

EUGENICS AND THE SUPERMAN.

What will be our attitude in the future with regard to heredity and eugenics? The profession as a whole takes very little interest in these subjects at present, but the man in the street a great deal. Is it right that we, who have to advise on the production of children, and of healthy children, should take no concern in the production of wise children? Accumulation of the results of mental tests on school-children is making it clear that heredity is an enormous factor in mental capacity. The uncritical man tends to jump to the conclusion that we can breed a race of supermen. There is a great deal of talk bandied about at present, that we take much trouble to breed good horses, dogs, sheep, and cattle, but allow human beings to mate at random. There is a probable source of fallacy in this argument. We breed our animals for single qualities such as strength, speed, large milk-supply, thick wool, or a faculty for retrieving. The human brain is an immensely complicated combination of different qualities and dependent for its success on the balance between them. It may be that there is a high correlation between these qualities, but we must not take this for granted. It is unlikely that for a long time to come we shall have sufficient knowledge to be able to con
even in any rude fashion, the factors that go to
making of a superman. A tiny nation with a pop
tion about equal to that of Portsmouth produce
about 200 years as much genius as the whole of
rest of the world in the whole of the rest of time. W
went to the making of this people?—a rude, war-
hunting northman from the forests of Central Eur
and a savage, superstitious, revengeful man livin
the shores of the Ægean. Who would have though
The miracle has not yet repeated itself. The nu
of permutations and combinations is too great f
repetition in so short a space as 2400 years.

Then, too, the production of a stable natio
dependent probably on a considerable varia
between the brains of its individuals. This enormo
complicates the problem. There seems to me l
chance of this kind of eugenics coming into the r
of practical politics in the near future. I hope
successors will have taken up the question before l
its importance and difficulty do not need emphasi

Such questions as whether sterilisation of ment
defective persons can eliminate the condition are r
medical. Medical indifference has led to c
logicians throughout the country advocating leg
tion for this purpose. A very little thought s
that high expectations will be disappointed. If me
deficiency is inherited as a Mendelian recessive,
claimed, the number of persons showing the cond
is very small compared to those that carry it in t
germ cells. Last year I took the trouble to work
the length of time it would take to reduce the cond
nearly to extermination point by the sterilis
method, even supposing that all cases were hered
and no fresh cases arose by mutation. I found it
into thousands of years. Subsequently I found
in 1917 Punnett had worked out the same thing
the U.S.A. figures. He showed that if the proporti
Mendelian heritable mental deficiency is 3 per 10
the population, it would require 250 generation
8000 years, to reduce it to 1 in 100,000 by the me
of sterilising those who show the character.

There are many possible avenues open to the me
profession in the future. We most of us like to ind
our fancies at times, and a little speculation hel
to be ready to take up with forethought our
altering duties.

The Principles of
SYMPTOMATOLOGY:
AN INTRODUCTION TO A NEW OUTLO
IN MEDICINE.

By Sir JAMES MACKENZIE, M.D. Edin.
F.R.C.P. Lond., F.R.S.

(From the St. Andrews Institute of Clinical Resea

In Three Parts.—Part II.

In Part I. (The Lancet, *Nov. 3rd) there was
lined the general problem of ill-health and the
outlook in its respect. The principle of the "r
arc" was explained.*

4. The Law of Fluctuation.

I have already mentioned that in trying to us
principle of the reflex arc it was some time befor
found out how to apply it in practice. Wh
occurred to us that the best way was to procee
resolving the arc into its component parts, we s
for instances where it could be applied. In
endeavour we used two methods, first by seekin
simpler forms of disease where not only the agent
the reactions could be recognised, and second
taking instances where the unit of the arc w
disturbance produced the symptom could be r
nised.

In seeking for the reactions easy of recognition, we only followed the practice of the physiologist who takes the simplest reactions, as the nerve-muscle preparation, to find the evidence of the most important laws which govern the production of vital phenomena. The occurrence of conjunctivitis following upon the lodging of a foreign body in the cornea was an opportunity of studying the principles of symptom production. The lacrymation, the blepharospasm, the injected capillaries, were recognised as being but the increased activity of normal reflexes; there was no new factor introduced. At the same time pain was felt, and it was reasonable to suppose that pain was produced in the same way—by increased activity of the organs normally regulating the function of the eye. From this way of looking at the matter, sensations are produced by the same process as the other symptoms—i.e., an increased stimulation is conveyed to the effector organs (lacrymal gland and muscles of the eyelid and the sensorium) and they respond by increased activity (lacrymation, blepharospasm, pain). A similar series of events occur in vomiting. Tickling the fauces may produce the sensation of nausea, a flow of saliva, then the act of vomiting. Here again the sensation of nausea was produced in the same way as the increased flow of saliva and vomiting. Hitherto, sensations have been looked upon as something distinct from objective signs, but a fuller knowledge of the reflex shows that they all belong to the same category of vital processes.

Another organ for observation that lies to our hand is the skin, and a number of extremely important deductions of universal application resulted from the more accurate investigation of skin sensations. We found that under ordinary conditions the sensibility of the skin varied in a remarkable manner. Areas of the skin may become hyperalgesic as a result of nerve injury, disease of the spinal cord, or from visceral disease. In my graduation thesis which was published in THE LANCET in 1883 [1] I described a case of hemiparaplegia spinalis in which there was an area of cutaneous hyperalgesia. The border of this area was not sharply defined, there being a region between the normal areas and hyperalgesic areas, where the sensibility may vary remarkably. Small areas were at one time extremely sensitive to touch and to pain stimuli, while other areas were insensitive. After a few minutes the former areas were no longer sensitive, while the insensitive areas have become sensitive. Further observation in cutaneous hyperalgesia in lesions of the nerves, in herpes zoster and in visceral disease revealed the same phenomenon. In our recent investigations the sensations of heat and cold in the normal skin were found to vary in the same way. These sensations are usually described as occurring in "spots." It was found that while there are spots that are sensitive to heat and cold, and spots that are insensitive, after a time these sensitive spots are no longer sensitive, while the insensitive spots become sensitive. These results have been described by Prof. Waterston.[2] [3]

In some people the skin has a mottled appearance, particularly in the legs or arms of the young. The mottling is due to pale patches mixed with patches of a darker hue. If one of these patches be surrounded by a line of ink, it will be found after a few minutes that the dark patch has become pale and the pale patch dark. In these dark patches the venules and capillaries were dilated, while in the pale patches they were contracted. From this we inferred that the capillary field was continually passing into a state of dilatation and contraction and vice versa. This variation in the sensations of the skin and in the capillaries we called "fluctuation," and led us to seek for its evidence elsewhere and we found that it is a phenomenon present in every organ which consists of active cells.

As we proceeded in the inquiry we found that it was impossible for us to understand the nature of the regulating process without a fuller knowledge of this matter, and Prof. Herring [4] has dealt fully with it elsewhere. The recognition of this law has compelled a closer inquiry into the function of cells, the result of which it is necessary to describe.

5. THE CELL.

There is a fairly common belief that for clinical medicine a superficial knowledge of physiology is all that is required, and that an accurate knowledge of details is only necessary for what is called scientific investigation in the laboratory. This is a mistake. The phenomena with which clinical medicine deals are far more subtle and more difficult to detect than the phenomena with which the physiologist deals. The disturbances which lead to the production of symptoms are often but the slightest departure from the normal, and are produced by agents far more delicate than those employed by laboratory experiment, while the result (or symptom) is so subtle as to be often beyond the capacity of a physiological instrument to register, though capable of recognition by appropriate clinical methods. The application of the principle of the reflex arc requires a knowledge of cell function of an intimate kind, and although the matter is dealt with in physiological text-books, it may not be amiss to recapitulate some of the main features of cell activity, and to dwell upon some features that have not received that attention which is their due.

The Excitability of the Cell.

All the special functions of fully-developed cells are to be found in a rudimentary state in the primitive cell. Many seemingly diverse functions proceed from the same root function—these root functions having become modified to suit a particular purpose, which the fully-developed cell has to fulfil. As a consequence, we find many terms used to describe processes which are fundamentally identical. A living cell takes in nourishment, and alters it so that it is transformed into different forms of energy, which, when discharged, appear as the specialised function of the cell, as contraction, secretion, conduction, perception of sensation, stimulus production, &c. The discharge takes place in response to a stimulus from without, so that the cell is excitable or capable of being stimulated. The susceptibility to stimulation varies, so that at one time a cell may respond to a relatively weak stimulus, at other times it may respond only to a much stronger stimulus, or there are times when it does not respond to any form of stimulation.

These variations in excitability are dependent on the nutrition of the cell. When the cell is fully stored with energy it is "excitable," that is, it is susceptible to a weak stimulus. When it has discharged its energy it is incapable of further effort till the store of energy is replenished, so that during the time it is discharging energy, and until some energy is restored, it is incapable of further activity, and so cannot respond to any form of stimulation. As its store is being replenished it becomes capable of discharging energy, and becomes more excitable. With the increase in the store excitability increases and the amount of energy discharged is also increased, so that a weak stimulus produces a maximum effect.

The conversion of food into the different forms of energy is chemical or metabolic, and can be accelerated or retarded by various agencies. The simplest agents are heat and cold. Alteration in the constituents of the cell as by food, drugs, secretion of glands, toxins of disease, and nerve influence (vagus and sympathetic) affects the cell like heat and cold. Many terms are applied to the varying phases of these functions, as excitability, inexcitability, refractory period, latent period, raising and lowering the threshold of stimulation, "all or nothing," inhibition, &c. It is to be remarked that all the vital processes concerned in the maintenance of life and the healthy activity of organs are dependent upon these primitive functions of the cell. Further, all the phenomena of ill-health, and death itself, are produced by a disturbance of these processes, and in one or other of the two ways indicated—an increase or decrease in excitability.

[4] The Law of Fluctuation or of Alternating Periods of Activity and Rest in Living Tissue, P. T. Herring. Brain, 1923, vol. xlvi., Part 2.

Impulse Production.

Among the specific functions of cells there are two which have not received that consideration which their importance requires—impulse production and control. Every cell when it discharges its function throws out at the same time impulses which affect neighbouring cells. The effect of their impulse can sometimes be demonstrated by the reactions which they produce on other organs. They may also be detected by delicate electrical instruments, as on the passage of an impulse along a nerve, or on the contraction of muscle. While these impulses may be expressed as an alteration in the electric potential, or in other ways, they nevertheless play an important part by their effect upon the process that regulates the function, not only of the organ whose cells produce the impulse, but also of those organs with whom they are related through the nervous system, or in other ways. We have studied some of the effects produced by impulses which are generated by the contraction of muscle cells, and some of our results will be discussed later, but there is reason to suppose that the generation of these impulses is not peculiar to muscle cells. This function of impulse production becomes the chief function of certain organs, as the sino-auricular node of the heart. In the cells of the node are generated the impulses which cause the contraction of the heart. In the same way among the functions of the higher centre in the brain is that of generating and discharging impulses such as those that cause the contraction of voluntary muscles.

Control.

Another somewhat vague influence exerted by certain structures is that of "control." I am quite aware that such a term, used as I use it, is unsatisfactory, and it is quite possible that the phenomena I attribute to this cause can be explained in other terms, but its use in a specific way calls attention to some important agencies at work, and though we may recognise their effects, we cannot clearly understand how the effects are brought about. While the most evident example is the control exercised by the will, as in modifying the rate of breathing and other instances, and which is called "inhibition," there are evidences of the presence of control independent of the will. In experimenting on the motor reflexes, Sherrington had to decerebrate the animal—that is, remove it from control of the cerebrum. In testing the knee-jerk, the reflex is said to be "reinforced" if the patient's attention is fixed, that is, if the control of the cerebral cortex is removed.

The principle that the function of an organ is not fully understood until it is lost applies to this control. When a motor nerve to a voluntary muscle is cut, the muscle is no longer under the control of the nerve, so that it cannot be made to contract voluntarily or reflexly, but it does not lie inert, but passes into a state of fibrillatory activity. Even when the control of the nerve is temporarily suspended the muscle may pass into this state, which disappears at once when the nerve resumes control. A similar effect is seen in the heart. When the sino-auricular node ceases to act the muscle fibres of the auricle pass into fibrillary activity. But more than that happens, for when the dominance of the S.-A. node is suspended the ventricular action becomes affected in a peculiar manner; its contraction becomes often incomplete, it becomes much more susceptible to stimulus by agents which increase or decrease its rate, and is often productive of extreme failure of the circulation. The recognition of this has opened a new phase in cardiology.

The Functional Part of the Cell.

We are accustomed to speak of the special functio of a cell as if it were the cell body which dete mines its peculiar function. While this is true i regard to muscle and secretory cells, it is not true i regard to many neurones. While all neurones ha the power of conducting impulses, in some there ma be a part endowed with other specific function These may be in parts far removed from the c body. Efferent neurones, like the sympathetic an vagus, have a specific influence on effector organ This specific influence is not a property of the c body, but lies in the terminal branches of the ner fibre (F, Fig. 1). This is shown by the result obtain in stimulating these nerves when they are cut; t characteristic effect is produced by stimulating t peripheral end—that is, when it is separated from t cell body.

In afferent neurones the characteristic functio is a property of the peripheral branches of the ner fibre in what is called the "receptor" (A, Fig. 1 The specific sensation of touch, heat, and cold a due to the peculiarity of their receptor branche The significance of this constitution of an affere neurone will be discussed in the study of the affere nervous system.

6. THE AFFERENT NERVOUS SYSTEM.

The importance of the afferent nervous system i maintaining health and in the production of sympton is not sufficiently recognised, while it is not realise how little is known of this portion of the nervo system. This lack of knowledge constitutes one the main reasons for the failure to understand t processes concerned in the production of symptom So far our knowledge of the afferent system is main limited to the nerves concerned in sensation, and the form but a small part of this system, but they ha bulked so largely that it has been assumed that th constitute the chief part of the system, so that a afferent nerves are spoken of as "sensory." T employment of this term has been unfortunate, f although in physiology it is often used as synonymo with "afferent," yet its use has led to a great de of confusion in other fields.

As our investigation proceeds we obtain evidenc of this afferent system in all parts of the body. T autonomic nervous system is spoken of as "a efferent system," and yet there is every reason f assuming that there is also an "afferent" system large and as important in the maintenance of life the efferent. As the special functional peculiarity the afferent nerve lies in the receptor end of t neurone (A, Fig. 1), if the nerve be cut stimulation either cut end does not call forth its special functio Thus, it would be futile to seek for the special functi of a cutaneous sensory nerve for the sense of touc heat, and cold by stimulating either cut end of t nerve. It is true the stimulation of the central e might cause a muscle contraction, but it would n produce these sensations, which reveal the function the nerve. So it is in regard to the afferent nerves the autonomic system—stimulating the cut en cannot reveal their peculiar function. Although t receptor part of the afferent nerve is not usuall capable of demonstration, yet the evidence of i presence is beyond dispute. It has been shown in o investigation on skin sensation that a specialise receptor for the stimulus which gives rise to the sens tions of touch, heat, and cold cannot be recognise yet when the skin is damaged the receptor is damage along with it, and these sensations cannot be repr duced by any form of stimulation.

As we proceed in our inquiry the presence an peculiar function of receptors in the viscera becom more and more apparent. The difference between t stimulation of a nerve by means of its receptor and i cut end can be seen in the case of the phrenic nerv If the peripheral end of a cut nerve be electricall stimulated, or if it be laid over the heart, the sam result follows, a sudden short contraction of th diaphragm. When, however, the phrenic nerve stimulated in the normal act of breathing—that is, by mpulses sent in from the periphery by afferent nerves o the respiratory centre—the contraction of the diaphragm is slow and gradual. It must be clearly recognised that a great many afferent nerves have receptors which serve other purposes than sensation. It may be taken for granted that every structure which s endowed with functional activity is supplied with both afferent and efferent nerve fibres. For the timulation of the afferent receptors an adequate timulus is required. Those which are concerned in the production of sensation require a particular kind of timulus; those concerned in other functions require also a particular stimulus.

This difference can be shown by applying a mechanical stimulus to the different tissues of the body. Touch, pinching, pricking, burning, heat, and cold give rise to definite sensations applied to the skin, but when applied to other tissues they may yield no sensation. Thus, one may prick with a pin the skin around the anus and produce pain, but if the pricking be continued into the mucous membrane of the bowel no sensation results. Indeed, most of the viscera can be handled, cut, torn, and burnt, and no sensation be produced. Yet we know that from some of these viscera impulses may be conveyed into the central ervous system which result in a great many manifestations, including pain. The inference from this is that ust as a particular kind of stimulus is required to ffect the skin receptors, so a particular kind of timulus is required to affect the receptors of the fferent nerves of the viscera. As the stimulus cannot be a mechanical one, it must be due to some vital process.

The organs of the healthy body are continually ubject to a stream of impulses which enter from without, or are produced in the body by the activity f the organs themselves. These impulses, wherever hey arise, are conveyed by the nervous system to the rgans and modify their functional activity. These mpulses have a far wider effect than is realised. This an be shown in many ways. The stroking of the skin nder the breast by a rough cloth produces a variety f effects besides the sensation of touch, as the production of a localised goose-skin, and of a widespread oose-skin, which appears on the chest and down the nner side of the arm. This may be accompanied by sensation of chilliness, due, in all probability, to a ontraction of the capillaries of the skin over the same egion as that in which the goose-skin appeared. In ddition, there may be a dilatation of the pupil. Such phenomena are evidences of effects produced in the entral nervous system by a slight stimulation of the kin. As we pursued our inquiry we found this preading of impulses in the central nervous system was the occasion of the production of a great many ymptoms in organs widely separated, as nausea, vomiting, sweating, pallor, and pain, as in renal olic.

Our inquiry then proceeds to find out what vital processes are adequate to excite the receptors. Many phenomena are produced by visceral disease which are dependent for their production on stimulation of the afferent nerves. In certain states of ill-health careful xamination of the abdomen reveals the presence of hard and contracted muscles, and of areas of tenderness, due to a hyperalgesic state of the skin and deeper issues of the external body wall. These phenomena indicate the presence of some disease process in the abdominal organs. Other phenomena often accompany these signs or appear without them, as nausea nd vomiting, increased pulse-rate, pallor, sweating, pain, &c. All these phenomena indicate increased activity of the afferent nervous system, and indicate urther the presence of some particular stimulus which s capable of acting upon the receptors of afferent nerves.

It has seemed to us that there are only a few actors which are capable of producing this adequate timulus, and in our research we are as yet able only o identify one—viz., impulses arising from the contraction of muscles.

7. The Generation of Impulses.

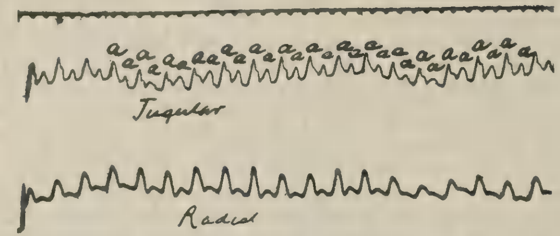
It is a matter commonly accepted that all the organs are linked together in such a way that one organ reacts upon the other through the nervous system. This has just been exemplified in describing the widespread effects resulting from a local stimulus from the skin and ureter. The generated impulses in one organ are taken up by the receptors of the afferent nerves and conveyed into the central nervous system and through it to the efferent nerves of the effector organs. While such an explanation is accepted, little is known of these impulses or how to investigate them. It is admitted that there is a continuous inflow of impulses from the skin and special sense organs—that indeed consciousness is dependent upon this. While this is recognised, we know little of the manner in which these impulses affect the organism. We think only of the brain, but almost certainly every organ of the body reacts to these impulses. It has just been pointed out that impulses from the skin gave rise, not only to the sensation of touch, but to a widespread goose-skin and dilatation of the pupil. These are in all probability only a few of the reactions that were produced. If it be considered how such stimulation arises from the skin with every movement of the body which causes the slightest friction, while impressions are also sent in from all the sense organs, we obtain a glimpse of the manner in which the function of organs may be influenced.

In addition to the impulses from without there are the impulses that arise in the organs themselves, which react upon one another. In the description of the function of the individual cell it was pointed out that in addition to its peculiar function it also had the faculty of throwing out impulses. These can affect the receptors of afferent nerves. Such impulses are not always easy of detection, not because the evidence of their presence is absent, but because it has not been understood how to link up the evidences with the parts concerned in the production of the impulses.

The impulses produced by muscle-cell activity are the easiest to demonstrate. One evidence has already been quoted in the experiment when the peripheral end of a cut phrenic nerve is laid over the heart. Impulses from the contracting ventricle stimulate the nerve, and these are conveyed to the diaphragm which results in a contraction, so that the diaphragm contracts regularly with each ventricular systole. It is these impulses produced by the contraction of muscle cells which give rise to the characteristic electric reaction of the electrocardiogram. In the condition called auricular flutter weak beats occur which can be counted. They frequently occur at the rate of 300 per minute. Lying in the wall of the auricle and exposed to these impulses is the auriculo-ventricular node. Stimulation of this node results in a contraction of the ventricle, so that we can count the number of impulses generated in the auricle by the rate of the pulse. At times the ventricle responds to every auricular impulse—more often it responds to every second. The reason for this is that the A.-V. node does not recover rapidly enough to be susceptible to every impulse from the auricle. This is represented in Fig. 5, which is a tracing of the auricular waves in the jugular (*a*), and of the radial pulse taken at the same time. The explanation of the tracing is given in the diagram Fig. 6. Here the auricular contractions are represented by the down strokes in the space AS—while the ventricular contractions (radial pulse) are represented by the downstrokes in the space VS. It will be seen that the auricular systoles are exactly double the ventricular. The space A.-V. represents the auriculo-ventricular node, and the shaded parts represent the period after its excitation when it cannot respond to a stimulus. It will be seen that every alternate auricular systole falls during this shaded period and its transmission to the ventricle is blocked by the refractory A.-V. node. The next auricular systole falls at a time when the excitability of the A.-V. node has returned, and so it transmits the impulse to the ventricle.

From these observations the conclusion was drawn that muscle cells when they function not only produce their peculiar effect, such as contraction, but also produce impulses capable of stimulating other cells. When this conclusion was arrived at the question arose, how this could be demonstrated?

FIG. 5.

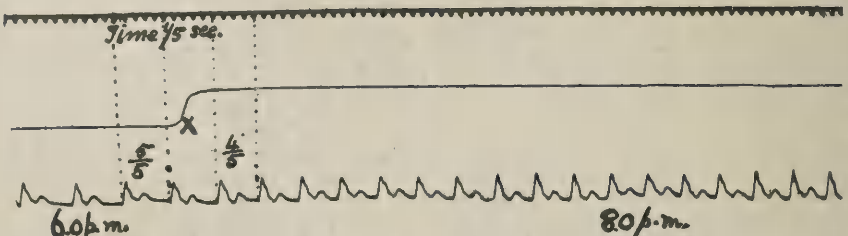


Tracings of the jugular and radial pulses during auricular flutter. The waves, *a*, are due to the auricle and are at the rate of 300 per minute. The alternation in the size of these waves is due to one beat of the auricle falling during ventricular systole, giving rise to the larger waves, and the other beat falling during the ventricular diastole. The rate of the radial pulse is 150, exactly half the auricular rate. The reason for this is shown in the diagram Fig. 6.

At first we bewailed the absence of delicate electric recording instruments, then we reflected that in the living body were means probably more sensitive, and we set about to find some way of demonstrating their presence. For a long time the mechanism of the increased heart rate in response to effort has been a puzzle, and it occurred to us to see if impulses from contraction of muscles could cause it. A continuous record was taken of the pulse of a man when he was lying on his back. After the rate had settled down he was asked to contract the muscles of his calf. Although it is at first difficult to do this without contracting other muscles of the body and holding the breath, with a little practice it can be done. When these muscles are contracted the rate of the heart begins at once to increase, and the increased rate continues for a short period after they are relaxed.

Fig. 7 shows this result. The signal X shows the time the muscles began to contract. The increase in rate begins with the second beat, and it lasted for four beats after the contraction had ceased. The rate rose from 60 beats per minute to 80. This is a fairly typical response—as it has been suggested that in making a voluntary effort, impulses from the cortex might affect the vagus, we sought for muscular effort which occurs independent of volition, and we took a number of observations on women in labour. On observing the onset of a uterine contraction before pain is felt and before the patient holds her breath or "bears down," the heart-rate increases. This is seen even in the early and slighter contractions, when the patient does not hold her breath.

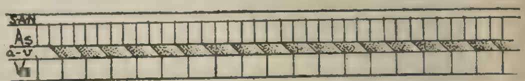
FIG. 7.



Showing the increase in pulse-rate on contraction of the muscles of the leg. The signal X indicates the time of contraction. The rate increased from 60 beats per minute to 80, and began after the first beat (from five-fifths of a second to four-fifths per beat) and lasted for a few beats after the contraction had ceased.

There are, no doubt, other factors concerned in maintaining the increase in rate during effort, but it is evident that the earliest is due to the contraction of the muscles, and some of these other factors may be the result of stimulation from the same source—an inference which is justified from the spread which occurs on stimulating the skin and in renal colic. What we are concerned with here is to establish the fact that, when a muscle cell contracts, impulses arise which are capable of stimulating afferent nerves.

FIG. 6.



The diagram of the events shown in Fig. 5. The upper space S.-A. N. represents the sino-auricular node which is out of action (compare Fig. 8). The downstrokes in space A.-S. represent the auricular beats at the rate of 300 per minute. The space A.-V. represents the A.-V. node. The shading represents the period when the node is not susceptible to stimulation. It will be seen that every second beat falls during this period, and there is in consequence no response by the ventricle. The downstrokes in V.-S. represent ventricular systoles as shown by the radial pulse in Fig. 5. They are half the rate of the auricular systoles. This diagram, like that in Fig. 8, illustrates the principle of the reflex arc in that it brings out where the disturbance occurs which results in an abnormal rhythm of the heart.

In Sherrington's discussion of visceral sensation[6] he points out that the receptors of afferent nerves are adapted to particular stimuli. "Adaptation has evolved a mechanism for which one kind of stimuli is the appropriate, *that is, the adequate stimulus.*" He goes on to point out that while mechanical stimuli as cutting, burning, &c., cause no sensation, certain forms of mechanical stimuli may do so, such as *distensile* stimuli. But distensile stimuli are only adequate provided they cause a contraction of muscle. One of the most powerful stimuli for contraction is stretching of the muscle fibres, as can be readily shown by giving a distending enema.

Muscle contraction is used here as an example because it provides such unmistakable evidence of the generation of impulses, but there is little doubt that every active cell produces them, although they are difficult to prove in the healthy body. In diseased states, however, symptoms are provoked which can only be explained in this way. In such diseases as gastric ulcer, appendicitis, the muscles of the abdomina wall may become rigidly contracted, and the skin and deeper tissues become hyperalgesic. It is quite justifiable to draw the conclusion that these phenomena are the result of impulses which arise in the diseased organ, and which are conveyed to the central nervous system in the manner described in the diagram Fig. 2.

GYNÆCOLOGY AND GENERAL MEDICINE:

THE RELATION BETWEEN CERTAIN DISORDERS OF THE FEMALE PELVIC ORGANS AND SYMPTOMS ORDINARILY CONSIDERED THE PROVINCE OF THE PHYSICIAN.[1]

BY HUGH MORELAND McCREA, O.B.E.,
M.D., B.CH., B.A.O. BELF.;
AND
VICTOR BONNEY, M.S., M.D., B.SC. LOND.,
F.R.C.S. ENG.

THE science and art of medicine form a subject so vast in range that no one mind can compass it in the brief span of life allowed. Most of us are specialists to a greater or less extent, concentrating on one or other of the many branches of medicine and producing by mass-action the world of medicine as a whole. If the advantages of specialism are manifest, so also are the disadvantages, for compartmental study (as we venture to call it) is very cramping to the mental outlook, tending to direct it to the part rather than the whole. It is only through general physicians that the assembled results of specialists are rendered of the greatest possible service to the patient. We regard the general physician as a liaison officer whose function is to correlate, harmonise, and dovetail the views of the specialists. We have heard it stated that the general physician, if not already "extinct," will very soon be crowded out of existence by the ever-multiplying horde of specialists. As one of us belongs to this threatened race he begs to protest that he is more necessary than ever.

The subject of this paper is the relation between certain disorders of the female pelvic organs and symptoms ordinarily considered the province of the physician, and we have introduced it because, unfortunately, there still exist among us physicians who never make a vaginal examination and gynæcologists whose conceptions end at the brim of the pelvis.

Early Conception of Gynæcology.

Gynæcology began as a department of medicine. This is well seen by the fact that it was recently incumbent on those aspiring to take up this specialty that they should become Members of the Royal College of Physicians of London. It has now become a branch of pure surgery, no doubt to its great advantage, and yet with a certain loss. Text-books on diseases of women, written upwards of 50 years ago, devote as much space to the consideration of symptoms collaterally affecting the body as a whole as to those directly located in the genital organs. Such terms as "sympathetic" and "reflex" which were applied to these symptoms when viewed in the light of to-day's knowledge, appear to be cloaks for ignorance, and as gynæcology became surgical they caused the reality of the symptoms themselves to be denied or ascribed to the vagaries of feminine mentality. It was Huxley who pointed out that one of the commonest errors is to discredit a truth because the arguments used in its favour are bad. The old writers were not wrong. Symptoms referable to the intestines, heart, lungs, and body generally may be primarily due to a disorder of the genital apparatus, not sympathetically nor reflexly, but by the agency of toxic absorption or bacterial action, conditions of which our forefathers knew nothing, or, as we will show later, to some alteration in the anatomical conditions of the pelvic floor, the consequences of which they failed to recognise.

We do not propose to waste your time by describing the effects on the general health that grossly patent diseases of the female genitals, such as advanced carcinoma or heavily bleeding fibroids, obviously produce, but to draw your attention to certain clinical states that ordinarily would not be suspected of having a gynæcological origin. For example, we have found intestinal stasis, genito-urinary infections, arthritis, fibrocytis, sciatica, choroiditis, neuro-retinitis, cyclitis, all directly resulting from a gynæcological lesion and all relieved by attention to the local condition.

Weakened Pelvic Floor.

Let us take for our first consideration the effects of a weakened pelvic floor, perhaps the disorder where treatment gives the most gratifying results. These may be intestinal stasis (which in its turn gives rise to dilatation of the bowel, with a facility for the absorption of toxins); displacement of the uterus (which may again lead to intestinal stasis, the result of obstructive constipation); rectocele (and, as will be seen later, possibly prolapse of the rectum); and cystocele (with its risk of infection of the genito-urinary tract, giving rise to symptoms which may pass unrecognised). Of these, intestinal stasis is by far the commonest, and has the most serious effect on the patient. It is much more common in women than in men, a fact immediately suggesting that the peculiarities of the female pelvis may play a large part in the production of the condition.

We proceed, therefore, to consider the several factors involved in the process of defæcation in a woman, and the results produced when these factors become weakened or inoperative. The factors involved in the act of defæcation are: (*a*) the muscular contraction of the wall of the bowel; (*b*) the rise in intra-abdominal pressure produced by straining; (*c*) the contraction of the fibres of the levatores ani, whereby not only is the pelvic floor prevented from bulging downwards under the increased abdominal pressure, but the anal canal is pulled over the advancing fæces.

(*a*) *Contraction of the Bowel Wall.*—The ease with which a motion is expelled depends upon the relation between the power applied and the resistance encountered. Given a sufficiently vigorous contraction of the bowel wall, a very large motion can be expelled by that force alone, the power being sufficient to overcome the resistance of the sphincter even against the individual's will and in spite of voluntary rigid tightening of the pelvic floor in the endeavour to prevent the action. This effect of a violent aperient is common knowledge. When from any reason the motion is liquid the expulsion of the bowel contents by the bowel musculature alone is still easier since the resistance is much less.

(*b*) *Rise in Intra-Abdominal Pressure, Produced by Straining.*—Normally, however, defæcation is not accomplished by contraction of the bowel wall alone, but is aided by voluntary straining, the abdominal muscles and diaphragm contracting so as to compress the abdominal contents. This expressional force acts on the rectum chiefly by the medium of Douglas's pouch, which forms a pneumatic wedge compressing the rectum against the rigid sacrum behind. We have no means of seeing what changes occur in the disposition of the parts during such straining, but judging from what is seen during an abdomino-pelvic operation when, from faulty anæsthesia or some other cause, the patient commences to strain, one infers that coils of the small intestine are crowded down into the utero-rectal space (always supposing the uterus is normally anteverted) and that these coils transmit the pressure to the rectum. That such pressure is merely auxiliary to the contraction of the bowel wall is, however, manifest when one considers what violent straining is required to pass a solid motion in the complete absence of peristalsis, though a semi-liquid stool is expressed easily enough. The poor development of the circular muscle fibres of the rectum (excepting at the sphincter), as compared with the longitudinal muscle fibres, suggests that constrictive peristalsis probably ends at the junction of the colon with the rectum, the contents of the rectum being expelled by *vis a tergo* of the constrictive peristalsis of the colon above, and the pneumatic pressure of Douglas's pouch, the longitudinal fibres of the rectum in the meantime making rigid its wall and pulling the anus over the fæces.

---

[1] A paper read before the Section of Obstetrics and Gynæcology of the Royal Society of Medicine, Nov. 1st, 1923.

(c) *Muscular Pelvic Floor.*—The muscles of the pelvic floor and the levatores ani in particular play an important part in defæcation. In the first place their contraction opposes a resistance to the downward pressure of the diaphragm and abdominal muscles which the act of straining produces, so that the abdominal pressure rises and the pneumatic wedge of Douglas's pouch becomes effective. If the pelvic floor were composed of easily stretched material instead of muscles capable of considerable rigidity, it would simply bulge under the pressure. In this event not only would the abdominal pressure fail, but the whole of the pelvic viscera, rectum included, would be pushed down en masse with the pelvic floor to which they are attached. Such a happening would mean a breakdown of the whole mechanism of defæcation, the essential of which is that the fæces alone should descend, leaving the rectum and the other pelvic viscera in situ. The levatores ani have a dual action on the rectum. The anterior fibres (or pubo-coccygeus) when contracting draw the anus towards the subpubic angle, narrow the vaginal entrance by lateral compression, and make rigid the front part of the muscular pelvic floor. The posterior fibres (ischio-coccygeus) tend to open the anus and draw it over the advancing fæcal mass, whilst at the same time they make rigid the posterior part of the muscular floor. This rigidity anchors the rectum, not only because the levator fibres have a direct attachment to the bowel, but because the lateral ligaments of the rectum are attached to the fascia covering the upper surface of the levators. Thus the normal act of defæcation is accomplished. Now let us consider what occurs when the main factors in defæcation are weakened or inoperative.

Importance of Douglas's Pouch.

It is a fact that all operations involving obliteration of Douglas's pouch are followed by obstinate constipation. The radical abdominal operation for cancer of the cervix is the best example of this. It is also true that all conditions which, by adhesions, inflammatory exudate, tumour formation, or displacement, cause the utero-rectal pouch to disappear, are similarly accompanied by constipation, always providing that the condition does not at the same time produce actual irritation of the bowel. It has frequently been stated that the presence of tumours or the retroflexed body of the uterus in Douglas's pouch causes constipation by direct pressure on the bowel wall. If the tumour or uterine body be big enough, direct obstruction in greater or less degree does occur, but we believe that the main reason for the constipation which characterises these cases is that the pneumatic wedge of Douglas's pouch has ceased to exist, owing to the filling up of the space by the tumour or uterus, as the case may be. What happens is well seen if, in the course of an abdominal operation on a patient whose uterus is lying back in Douglas's pouch, the patient begins to strain. The intestinal coils are then thrust forward in front of the uterus, entirely obscuring it, whilst the irritable surgeon, vainly endeavouring to dam them back, damns the anæsthetist instead.

Hence the loss of the pneumatic wedge of Douglas's pouch produces a form of constipation in which there is difficulty in expelling the fæces from the rectum unless the deficient expressive force is made up for by the increased peristalsis of the bowel wall and greater fluidity of the motions, to obtain which the patient habitually employs aperients. When the retroverted uterus is large it actually acts like a ball-valve, pushing upon and actually hampering the bowel behind it, and the same is true of tumours closely fitting the utero-rectal space. In this class of case primary dilatation of the pelvic colon is produced, with results which we will consider presently.

We might notice here an instructive case of this variety of abnormality; the patient consulted one of us early in the year. She was unmarried, aged 33, and gave a history of loose stools for a period of over three years, at times the actions amounting to urgent diarrhœa, with a previous history of marked constipation. The condition was always worse at the time of the periods. Menstruation was regular, but was always associated with pain the first day. X rays, bacterial and other examinations failed to reveal any abnormality except a markedly retroflexed and enlarged uterus. The abdomen was opened by the other of us, a careful examination was made, but nothing further was found. The round ligaments were shortened. She has been seen recently, the bowels are acting regularly every day, the general condition is vastly improved and her weight is steadily going up.

Production of Cystocele and Rectocele.

Now let us consider some further effects of a weakened pelvic floor. In women whose muscular pelvic floor has been stretched by childbirth it is the anterior part of that floor (the pubo-coccygeal segment) which is chiefly weakened, so that the defective levators cannot properly close the pelvic outlet in front, a gap remaining where the much enlarged vagina passes between them. It is well recognised that the degree of dropping of the anterior and posterior walls respectively is unequal, one or the other being chiefly or solely affected. We suggest that the inequality can be, in part at least, explained by the position of the uterus, the tendency to cystocele being greater when the uterus is retroflexed and the tendency to rectocele greater when the uterus is anteverted. In cases of retroversion the altered direction of the pneumatic wedge by the body of the uterus filling Douglas's pouch forces down the bladder and the ledge on which it rests. This ledge is formed by the cardinal vaginal ligaments (Mackendrodt's ligaments) on either side, with the anterior vaginal wall and pubo-cervical muscle sheet in the centre. On the other hand, with the uterus anteverted the pressure is directed on to the posterior part of the floor (the ischio-coccygeal segment) to which the lower end of the rectum is attached, and as this, as a rule, escapes injury, every act of straining pushes the rectum downwards and forwards in the direction of least resistance, and the outcome is a rectocele. If the posterior part of the pelvic floor were more weakened than the anterior part, the rectum would then be pushed straight downwards instead of downwards and forwards, and this in fact is what happens in those cases in which the rectum prolapses through the anus.

An interesting case of this type was seen over a year ago. The patient came to consult one of us on account of prolapse of the rectum. Pelvic examination showed a marked dropping of the pelvic floor. Anterior and posterior colporrhaphy was performed, the uterus was then ventrofixed and the front of the rectum stitched to the posterior wall of the uterus. Since that time there has been no return of the prolapse, and the patient's general condition is entirely satisfactory.

The downward and forward movement that produces a rectocele drags on and loosens the attachment of the rectum to the sacrum and stretches the lateral rectal ligaments, and this movement, carried out against the resistance of the attachments named, presently permanently stretches and thins the wall of the bowel itself, so that it becomes functionally weaker. That the bulge of a rectocele is due to the actual descent of the bowel, and not to flatus or fæces pressed into the primarily thinned and weakened viscus by the act of straining, can be demonstrated by passing a rubber tube into the rectum and then making the patient strain down. It will be found that the size of the rectocele capable of being protruded is not lessened by the presence of the tube, though a free way exists for the escape of fæces or flatus. Descent of the rectum is often accompanied by an elongation downwards of Douglas's pouch, but a moment's consideration shows that this will not make up for the rectal deficiency, for the pneumatic wedge presses forward towards the gap between the levators, and not downwards and backwards as it should do.

The bulged, elongated and thinned condition of e rectum thus produced results in a form of conipation where, though solid fæces may be driven y peristalsis into the rectum, they are unable to be pressed from the anus with any ordinary exercise force, because the resultant of pressure is in the rong direction, and because the bowel and fæces scend together as the patient strains. Patients uffering from this disability complain they have st their expressive power, and they resort to the abitual use of aperients which, by increasing perialsis and fluidising the fæces, temporarily at all vents abrogates the difficulty. The pathological rocess, however, is a progressive one, the laxity of e parts increasing with every effort made, and the istended and thinned condition of the bowel tending extend upwards until the pelvic colon and, later n, the rest of the large bowel may be dilated. It is ossible that we have here a cause for diverticulitis, much commoner in women than in men.

In a considerable portion of these women the terus is retroverted and low in the pelvis in addition, ith the results already described—namely, that e pressure of the intestinal coils when straining is iverted forwards into the utero-vesical space and he pneumatic wedge of Douglas's pouch is lost. hus the difficulty in emptying the lower bowel is creased, and where the uterus is large enough to ct like a ball-valve, hampering the bowel behind it, xtension to the pelvic colon of the lax condition lready affecting the rectum is much assisted, and a hinned and dilated pelvic colon, sooner or later, is ertain to result.

Permanent dilatation of any portion of gut having mesentery necessitates permanent increase in size f the mesentery, not only as measured along the esenteric edge, but as measured from its root to s edge. In the case of the pelvic colon this elongaion is accentuated if the uterus is retroverted, on ccount of the fact that a large free space becomes vailable in front of the uterus, into which the coil f gut prolapses, and the mesenteric "drag" thus roduced is continually tending to accentuate the eformity. In this class of patient, too, the abdoinal wall is usually lax as well, and there is general nteroptosis. So that all the conditions for intestinal tasis are present. In such patients a vicious circle xists, the primary defect in the pelvis being accenuated by the ill-health and tissue-weakness produced y the stasis originating from the pelvic deformity. ike other vicious circles, it is often difficult to letermine the starting-point of the cycle, and in hese cases, unless a vaginal examination be made, t will probably be overlooked.

Clinical Features of Stasis of Pelvic Origin.

At the outset patients may be divided into two groups: (1) those who frankly complain of pain or liscomfort in the pelvis (these invariably consult he gynæcologist); and (2) a much larger class, those whose symptoms do not at first suggest anything wrong in that region, and who directly consult a physician. We will discuss the second of these two groups, for professional opinion up to now has not ssociated the symptoms with pelvic abnormalities. Most of these patients complain of obstinate contipation, and they usually describe the condition as ne in which they have no longer the muscle-power necessary to expel the stool. Others complain of "feeling so weak," that they are all right so long as they are lying down, but that they tire on slight exertion and are disinclined to make any prolonged effort. An inquiry may elicit that their disability dates from a confinement, previous to which they were normally active and strong. They say that they "don't feel the same as they used to do," and in fact they *have* been physically altered by the labour. They are as a house whose foundations have subsided, the very basis of the support of the viscera having yielded. Patients of this sort, with a total absence of localising symptoms, are commonly treated by tonics, rest, general massage and so forth, the underlying cause of the complaint of general weakness being entirely overlooked because nothing directly points to the genital organs. More commonly, however, the patient has grown so accustomed to inactivity in her bowels that this is not her chief complaint on consulting a physician. She even conveys to the physician by her answers that nothing that he can suggest will relieve that except the taking of aperients, a matter in which she is a greater expert than he is, and that it is merely the penalty of having children. Rather she seeks aid for indigestion, or even heart disease.

Complaint of "Heart Disease."

It may come as a surprise to the gynæcologist that he may be of assistance in a case of heart disease. One must explain at once that when a patient consults a physician stating she has heart disease it is an extremely uncommon thing to find any organic disease. Usually some type of arrthymia is found, and this, from the sensations associated with it, has suggested the diagnosis of heart disease to the uninitiated. A commonly accepted cause for this condition is flatulent distension of the stomach, but a distended splenic flexure of the colon may produce the same result. Now we have already seen that this may be part of the disorganisation produced by a weakened pelvic floor, and in the repair of this anatomical derangement the gynæcological surgeon can relieve the patient of her cardiac symptoms.

A case of this type consulted one of us some years ago. She came complaining of "heart disease," palpitation on the least exertion, associated with a certain amount of dyspnœa. She was a woman of 42, and had had four children. Examination revealed a dilated splenic flexure and descending colon. An inquiry elicited the fact that she had lost the muscular effort to evacuate the stools, and that the bowels were not moved without a strong purgative. Vaginal examination showed a great laxity of the pelvic floor, with the uterus anteverted. An operation was advised for the repair of the vagina and perineum and this was done. She has been seen again recently, and her history since the operation has been one of a normally functioning heart. This type of "heart disease," due to pelvic derangement, is not at all uncommon, and unless one is on the look-out for it, it can be easily missed.

Complaint of "Indigestion."

It is more usual, however, for the patient to complain simply of indigestion, due to a condition of flatulent distension of the abdomen, much worse after food. The stasis we have described is accompanied by dilatation of the colon with a consequent partial loss of peristalsis, and it is to this that most of the symptoms complained of are directly due. Again, stasis without doubt produces an alteration in the flora of the intestinal tract, both in quality and quantity, and this, together with the thinned and altered condition of the bowel, leads to toxic absorption, and in some cases to bacterial transmission. We do not propose to spend time discussing the effects of absorption or transmission, but would point out that the indigestion, headaches, and general ill-being which singly or in conjunction are complained of by these patients at first sight bear no relation to the genital organs, and yet may be directly responsible.

We believe that the findings of those who have written on stasis are not the only explanations for its existence, and that when a woman consults a doctor for symptoms apparently due to stasis, a vaginal examination should be made before the already accepted causes are held responsible for the condition. Headaches, general debility, indigestion, and so forth are too often treated as entities by the physician, but we maintain that in many female patients they are merely signs, and that the original cause is displacement of the genital organs and pelvic floor, and that, until this is corrected, complete and permanent cure of the symptoms will not be achieved.

Patients of the type we have been describing invariably consult a physician and not a gynæcologist, and unless the former proposes to make a vaginal examination, and is willing to make liaison with the gynæcologist, the patient is unlikely to be benefited to any great extent.

We have thus seen that a weakened pelvic floor may be held accountable for, or may result in, intestinal stasis, dilatation of the bowel, possibly diverticulitis, and general toxæmia, which latter is so often treated as neurasthenia without the origin of the condition having been discovered. Further, patients suffering from cystocele do not primarily consult a physician, and yet this disorder may cause conditions with which it is the duty of the physician to deal. It may, if at all marked, lead to partial retention of urine, as the patient is unable with the act of micturition completely to empty the bladder; these patients, in order to prevent a too early return of the desire to micturate, press during micturition the anterior wall of the vagina upwards with the finger, and so accomplish a complete evacuation of the bladder. Thus a condition of partial retention really exists very much like what is found in the male suffering from an enlarged prostate. It is well recognised how easily this urine in the male may become infected, and in a similar way, more easily owing to the shortness of the urethra, infections may arise in the bladder of patients suffering from cystocele.

The gross infections causing acute cystitis are easily recognised, as the patient seeks the aid of the physician for this condition. But in many the condition is not acute and causes no local symptoms, but gives rise to disorders elsewhere. The clinical aspects vary according to the infecting organism. The chronic infections with *Bacillus coli*, the typhoid group and pyocyaneus, may cause no frequency of micturition or pain to the patient, but may be responsible for chronic ill-health, debility, and a general feeling of malaise. The same symptoms may be directly due to a chronic streptococcal infection, again without localising symptoms, but in addition there may be symptoms of affections in joints and muscles.[2]

Undoubtedly these infections may be conveyed to the bladder by the urethra, and as this is so, an examination should be made of the vagina, as vaginal discharges are only too commonly the cause. These may come from a torn cervix. Cervicitis may give rise, in itself, to a marked toxæmia, and it has been in our experience to find arthritis arising from this condition. These toxic conditions usually clear up with local treatment to the affected part, and in the cases of arthritis it may be necessary to repair the injured cervix, and in addition we have found vaccines very helpful.

A case illustrating the importance of a complete pelvic examination, and carrying with it a salutary lesson, might usefully be inserted here. A very advanced case of arthritis consulted one of us a year ago. Both knee-joints were seriously affected, and the small joints of the hand showed a considerable amount of deformity. When seen the patient had already had all her teeth out, and her tonsils had been removed and the intestinal flora investigated, but so far she had obtained no relief. Vaginal examination showed a fairly marked cystocele and a torn cervix. No vaginal discharge was detected at this examination. A catheter examination was taken, and the urine showed a pure streptococcal growth. The patient underwent a course of vaccine treatment with this organism over a period of about four months with very satisfactory results. It was then discontinued, but two months later the symptoms recurred, when she came to consult one of us again. This time a vaginal examination showed a heavy discharge coming from the cervix. On inquiry it was elicited that the recurrence of the symptoms synchronised with the appearance of this discharge. A culture was taken from it and also from the urine, and in both a streptococcal infection was found. A fresh vaccine was prepared, and this is giving eminently satisfactory results

In this case there is little doubt that the bladde infection was only secondary to the cervical, and had the latter been properly investigated the patient would have been saved a great deal of suffering.

Other Gynæcological Conditions.

Chronic infections of the tubes cause very marked symptoms of toxæmia, and again arthritis may have its origin here, particularly when the infection i gonococcal. Ovarian troubles do not give ris commonly to general conditions outside the pelvis and when they do the local trouble is the condition for which the patient asks for relief, but small cysts fibromata, or malignant growths may give rise t symptoms from pressure, and in the early days o these conditions the pressure symptoms are frequentl the only thing of which the patient complains During the last few years we have seen several case of distressing sciatica in young unmarried girls. I none of these had a vaginal examination been made and so an impacted dermoid cyst had, in each case escaped observation. On removal of this tumou all signs of sciatica disappeared. This cannot bu strengthen our claim that a pelvic examination i necessary to complete one's investigations, whethe the patient be a virgin or a married woman.

Infections of the eye may even come within th sphere of the gynæcologist, and it has been ou privilege to see a case of neuro-retinitis cured an another of choroiditis in which the condition wa completely arrested by dealing with the site o infection in the pelvis. One case was sent to consul one of us by Mr. Ernest Clarke, on account of sever attacks of pain in the head which occurred five o six times a day, and were associated with partia blindness. He reported it as a case of neuro-retinitis with hæmorrhages. Every site for a possible infectio was explored, and finally a catheter specimen of th urine was examined as a cystocele was present. Thi was found to contain pus cells and epithelial cells mostly from the renal pelvis, and a fairly heav growth of streptococci. A vaccine was used over period of nearly five months, and in the end the retin became normal, and she recovered her sight completely. The other case, a patient of Dr. A. M. Elliot's was one of choroiditis, which had already destroyed the sight of one eye, associated with a severe cervica tear with a purulent streptococcal discharge. A tota hysterectomy was performed and the result was complete arrest of the condition, and up till this tim there has been no return.

Before closing let us revert again to intestina stasis. A perfectly legitimate query may here b interposed—namely, how our conclusions have bee arrived at. The answer is as follows. One of u (McC.), as a result of his experience of cases c chronic constipation and intestinal stasis, had becom aware of the existence of a distinct class of patien in whom the most exhaustive examination revealed nothing except deformity of the genital organs and pelvic floor. Careful consideration of these cases led him tentatively to the conclusions just set forth, and determining to put it to the test of operative intervention, he discussed the matter with the other o us (V. B.), whom he found had formed certain definit views which bore on the subject. Of these th importance of Douglas's pouch and the muscula pelvic floor in the mechanism of defæcation, and th physical results that follow if they become inoperative have already been mentioned. He further had noted that the operation of shortening the round ligaments when performed so that the organ is not merel anteverted but pulled high up as well, effected a unlooked-for improvement in symptoms due t enteroptosis when that condition complicated retroversion, and he had ascribed that improvement to th uterus and broad ligaments forming a firm platform so to speak, on which the intestines could rest.

---

[2] It should be noted that some of the most active organisms causing general symptoms may not appear on the plate even up to ten days' incubation, and it is wise to continue the incubation of tubes that appear sterile at the end of the second day.

The physician's views were therefore put to the test, and in a series of cases the pelvic deformity was repaired with the definite object of curing the stasis. The operations performed differed in different cases according to the nature and extent of the deformity. If the uterus was retroverted, the round ligaments were shortened by a method which virtually suspends the uterus on either side at its junction with the round ligament, but which leaves the corpus itself free. Laxity of the pelvic floor was dealt with by a colporrhaphy which included very firm and thorough suture of the levatores.

The result of these operations has been so happy as to convince us that the conclusions theoretically reached are right. The most satisfactory results of all have been in women whose pelvic floor had been thoroughly deranged, but cases of simple backward displacement of the uterus have also given markedly good results. The sense of well-being after these operations have been safely accomplished is the outstanding feature in the records of all the patients; in fact, there is no class of operation in surgery that we know of where the patients themselves are so grateful. It is because of this that we determined to bring this type of case before the section. The subject up to now has scarcely been touched upon, the only writing bearing on it that we know of being contained in Arthur Hurst's book on constipation, in which weakness of the pelvic floor is specifically referred to as a cause of constipation. We do not claim that the last word is said on the subject, nor that our explanations or conclusions may not be modified by future experience and observation, but we do believe that in the main our contention is right.

In conclusion, we trust we have shown that general conditions may be dependent on pathological lesions in the pelvic organs and have proved the necessity of a pelvic examination to be a part of the general examination made by the physician, and we trust we have thus succeeded in bringing more closely together those great fields of thought—namely, general medicine and gynæcology.

UNSUSPECTED NASAL SINUS DISEASE.

BY T. B. JOBSON, M.D., B.CH. DUB., D.P.H. LOND.,

EAR, NOSE, AND THROAT SURGEON, ROYAL COUNTY HOSPITAL, GUILDFORD; REGISTRAR, CENTRAL LONDON THROAT HOSPITAL; AURAL SURGEON, MINISTRY OF PENSIONS, LONDON.

NASAL sinus disease is much more common than is generally recognised, the reason being that the nose does not receive the attention it deserves. It is quite common to see patients suffering from sinus suppuration whose symptoms date back 5, 10, or even 20 years. Their symptoms and signs of nasal disease are often slight. Probably the patient has had treatment on one or more occasions; a nasal wash has been prescribed and used without much improvement in his condition, and he comes to regard the latter as "chronic" and resigns himself to what he thinks is the inevitable.

Capacity of the Nasal Sinuses.

Although the signs of a chronic sinusitis may be slight, the condition is very serious. The size of the nasal sinuses is apt to be forgotten among the mass of anatomical knowledge the student has to learn. A brief outline of their measurements may help in the appreciation of their importance.

—	Dimensions in centimetres.		
	Frontal.	Maxillary.	Sphenoidal.
Antero-posterior ..	2·1	3·8	2·1
Supero-inferior ..	3·4	3·8	2·2
Lateral	2·3	2·3	1·8

The frontals and sphenoidals vary very greatly in size. One may be immensely larger than the other, much bigger or much smaller than the average quoted. The cubic content as given by Loeb[1] shows this very strikingly.

—	Content in cubic centimetres.	
	Greatest.	Least.
Sphenoid	11·8	0·6
Frontal	8·2	0·9
Maxillary	28·4	4·6

The ethmoids, of course, are much smaller in size but make up for this in their greater number. The maxillary antra are the most constant. Their shape and dimensions may be well compared to a Brazil nut of moderate size. With this idea of the capacity of the nasal sinuses one can visualise what happens when one or more of these cavities are infected. They are constantly secreting pus, a good deal of which is swallowed. The toxins are absorbed both by the mucosa of the sinus and of the intestinal tract; a chronic toxæmia is produced, which may show itself in many ways—e.g., headaches, arthritis, or nephritis. The pus swallowed may set up infection at any point in the intestinal canal, producing tonsillitis, gastritis, appendicitis, colitis, &c. The toxins may produce effects further afield, such as optic neuritis, arteriosclerosis, arthritis, &c. Acute otitis and tonsillitis are obvious conditions that may arise from pus passing down the posterior nares.

The recognition of a possible focus in nasal sinuses is of great practical importance. Treatment of the secondary conditions produced by sinus suppuration will produce little benefit while the toxic source is still present. Surgical treatment of the sinuses gives excellent results. In cases of fairly recent antral disease puncture and lavage will often effect a cure. Even in long-standing cases and when more than one sinus is involved the appropriate radical drainage operation gives most satisfactory results. Early diagnosis is thus of very great importance.

The following series of cases shows how the signs of sinus disease may be masked or referred to a remote part of the body.

The Onset of Acute Sinusitis.

Visualise for a moment the onset of an acute sinusitis following coryza. The normal mucous membrane of the nose is sterile. The skin and vibrissæ of the vestibule of the nose are septic. Very interesting experiments to prove this were done some years ago by StClair Thomson and Hewlett.[2] All day long the nasal mucosa of the town-dweller is bombarded by bacilli of various kinds, which impinge on the moist surface of the septum and turbinal bones. Here they have to contend with the defensive mechanism of the nose—the antiseptic action of the nasal secretion, the excellent blood-supply of the nose, and the mechanical action of the ciliated epithelium. Usually the defence succeeds. Occasionally, however, owing to the number or virulence of the attacking organisms or to a lack of vigour in the defending mechanism, the attack gains a foothold; a resulting rhinitis spreads through the ostia connecting the nose with the various sinuses. The inflamed mucosa secretes muco-pus, which overflows into the nose. The ostia become narrowed through the swelling of the covering mucous membrane. This tends to partial damming up of the secretions, causing acute headache, pyrexia, and toxæmia. As a rule these symptoms pass off in a few days with suitable treatment, and the sinusitis clears up. Occasionally, however, perhaps in 5 per cent. of cases, the invading organisms gain a permanent stance. A subacute or chronic sinusitis is the result.

A nasal infection secondary to influenza, scarlet fever, or any of the infective diseases may cause a sinusitis in a somewhat similar way. A distinct class of cases are those caused by dental sepsis. These, of course, are, in the first place at any rate, limited to the antra and comprise about 20 per cent. of chronic antral disease. The sinusitis having passed through the acute stage to the chronic may show little or no signs of its presence. But there it remains as a septic focus ready to flare on provocation, and a source of infection to other parts of the body. To realise the possibility of its existence will elucidate many obscure conditions.

Illustrative Cases.

The following cases are examples of illness in which there was a sinusitis present, the existence of which would not have been detected unless routine examination had been made.

Acute Otitis Media.—A single woman, aged 40, came to me on Dec. 12th, 1922, with a history of acute otitis with pain and discharge from right ear for one week. No previous attacks. The membrane showed the typical red, swollen appearance of acute otitis, and a perforation in lower half. In spite of a month's treatment and myringotomy the ear still discharged profusely. No obvious source of sepsis in mouth or throat. She gave a history of catching frequent colds—a history that often points to sinus infection. On exploring the antra I found the right full of muco-pus. After four irrigations the nose cleared up completely. The ear improved at the same time and was quite dry on Jan. 18th, 1923.

In this case it is quite probable that the pus from the antrum was the original cause of the otitis. The pus passing down the posterior nares might easily infect the Eustachian tube. At all events the septic antrum aggravated the otitis, which resisted all treatment until the septic focus in the nose was eliminated.

One frequently sees in children an otorrhœa resisting all treatment while septic adenoids are present. After removal of the adenoids the otorrhœa clears up. A septic sinus can act in the same way. Although not so common, it should not be forgotten as a possible cause.

Bad Breadth.—A girl, aged 19, came to the Guildford Hospital on Nov. 2nd, 1922. Her only symptom was "bad breath." She had no headaches or pain, complained of no nasal discharge, and in fact felt perfectly well. She was a domestic servant; the fœtor from her breath was a great handicap to her in her work, and had been a source of distress to her in social life for over three years. Puncture of the left antrum yielded creamy fœtid pus. Treatment by irrigation failed to cure, so I did a radical Caldwell-Luc operation. After a week she was practically well, and has had no trace of "bad breath" since. Previous to coming to hospital this girl had been treated for "dry" catarrh of the nose. Probably the case had been diagnosed as ozæna. A glance at the interior of the nose should have negatived this diagnosis. Also the girl was acutely conscious of her own bad breath. The fœtor was both subjective and objective. In ozæna it is objective only.

Cases of "bad breath" are frequently put down to bad teeth, "disordered stomach," constipation, &c. A septic mouth is, indeed, frequently the cause, but where the mouth is clean the nose is probably the source. It is exceptional to find bad breath as the only symptom of sinus disease. It is usually found combined with discharge, headache, and ill-health.

Perpetual Colds.—A man, aged 59, seen Jan. 2nd, 1923, complained of a "perpetual cold" affecting both sides of his nose. Symptoms dated back five years but could not be traced to any illness. No headache or tenderness; sight and sense of smell good; no fœtor detected from the discharge, although he volunteered that instead of handkerchiefs he used old pieces of linen which could be burned. Anterior rhinoscopy showed a typical picture of chronic sinusitis. On the right side a mucous polypus blocked the view; on the left side the anterior end of the middle turbinal was outlined in pus, the "creamy crescent" I like to call it, which tells of pus in the anterior group of nasal sinuses. Proof puncture on both sides yielded fœtid creamy pus which mixed readily with the irrigating fluid. This miscible pus always indicates old-standing disease. The probability is that such a case will not clear up with puncture combined with injection of antiseptic. The case required a radical drainage operation—a double Caldwell-Luc operation with removal of the ethmoid cells on the right side.

Vaccines are quite useless in these chronic cases. The mucous membrane is degenerated. The blood of the vaccinated patient, although it may have much added antitoxin and increased antibodies, does not reach the organisms in the septic pool and does not circulate efficiently in the degenerated mucosa. In the acute and subacute cases, however, vaccine is no doubt of help in treatment, although it is often difficult to judge on this point, as the patient is rapidly getting better by the time the vaccine is ready for use.

Head Injury.—A carman, aged 20, sent to Guildford Hospital on Dec. 13th, 1922, as a case of head injury, possibly with cerebral hæmorrhage. A week previous to admission the door of his van had struck him on the left fronto-parietal region. He was dazed by the blow, but resumed work next day, although his head ached and was tender to touch. Two days after the accident his nose bled; headache became very severe—intense boring pain round left eye prevented sleep. On admission he was mentally quite clear; his chief complaint was of the headache, and he was tender over the left malar and frontal regions. Temp. 99° to 100° F. Mr. Milligan, the house surgeon, noticed a nasal discharge on left side. Mr. H. B. Butler, the surgeon in charge of the case, asked me to see the patient. I found an acute purulent sinusitis on left side with typical creamy crescent. Turbinal bones showed extreme engorgement, completely blocking the nose on that side. Puncture of left antrum yielded creamy pus. After lavage pus could still be traced coming down from ethmoidal area, indicating infection of anterior ethmoidal cells. X ray examination showed left antrum and left ethmoid opaque—but frontal sinuses clear. Pus from antrum yielded staphylococcus from which a vaccine was made and given. With treatment he gradually improved; it took over a month to get the nose free from pus. In fact, I had put him down for a drainage operation when he showed a sudden improvement and the sinuses cleared up completely. His symptoms, headache, tenderness, and fever had disappeared after ten days of treatment. On questioning him it was found that he had had a "cold" for a month previous to his head injury. Whether the blow had any exciting influence on the sinusitis it is hard to say. Probably not.

The moral is that here we have a case sent in by a most competent doctor as a possible cerebral hæmorrhage. This case might easily have been trephined had not the possibility of coexisting sinus infection occurred to the surgeon in charge.

Duodenal Ulcer.—A woman, aged 39, admitted to Royal Surrey County Hospital, Guildford, for recurring gastroduodenal symptoms for some years, suggesting a duodenal ulcer. She was referred to me for preliminary treatment on Nov. 9th, 1922, when I enucleated the tonsils. On seeing her again I found pus in the left nostril and got a history of nasal discharge for over a year, and frontal headaches "as if there was something drawing her eyes." Exploration of the left antrum yielded creamy pus mixing with the irrigating fluid. On Feb. 16th, 1923, a laparotomy was done by Mr. E. W. Sheaf, who found no ulcer in stomach or duodenum.

Sir Berkeley Moynihan, in his Hunterian lecture delivered on Jan. 29th, 1923, on Some Problems of Gastric and Duodenal Ulcers, says: "Before treatment begins a general survey of the patient must be made, especially in reference to the existence of sources of infection in the mouth and the accessory sinuses." The above case well illustrates this point. If the infection sources can be eliminated early enough the gastritis will clear up before the ulcerative stage is reached.

Pyrexia.—A boy, aged 9, had an attack of "influenza," with some tonsillitis and nasal catarrh. These symptoms cleared up, but the temperature persisted. For three weeks it kept up to 103°, 104°, and even 105° F. in the evening. No cause whatever could be found for the fever. He felt, slept and ate well; he was seen by four doctors and carefully examined, and the doctor in charge finally asked me to examine the sinuses. Both antra contained pus. A double drainage operation was done. The temperature fell by lysis to normal in a few days. Another interesting point about this case is that the boy had developed albuminuria. This also disappeared three days after the operation. This case I have published in a previous paper,[4] but I mention it again as being unique in my experience.

One of the commonest symptoms of chronic sinusitis is headache. This is most commonly frontal. In acute maxillary, ethmoidal, and frontal cases it is a brow ache. In chronic cases the pain is higher. Occipita headache points more to sphenoidal sinus. The headache is usually matutinal; the patient wakes with a dull pain which lasts for some hours, until by the help of the upright position, drainage and other factors such as blowing or washing out the nose, the pent-up secretions are partly evacuated, thus relieving tension. Headache may be the *only* symptom of chronic sinusitis, as the following case and many others show.

Headache.—A girl, aged 17, had suffered for seven years from headaches of supra-orbital type generally on the left side. No other symptom than almost continuous headache. Transillumination showed dullness on left antral region. Lavage of left antrum discovered an empyema of fœtid pus. After the second lavage headaches entirely ceased. She is still under treatment as the antrum is not yet free from pus. A drainage operation may be required.

The contents of the antrum may be a clear straw-coloured sterile fluid which gushes out when the trocar is introduced. This retention of fluid is due to the antral ostium being obstructed by an enlarged middle turbinal or a deflected septum or other anatomical defect. Treatment of these cases resolves itself into restoring the patency of the ostium by rectifying the anatomical defect.

It is not uncommon to meet cases in which the operation for removal of adenoids has been performed on one or more occasions, and yet in spite of this treatment the patient still has a "wet nose." On palpating the posterior nasus one feels a soft, raised patch in the adenoid area. One is apt to jump to the conclusion that the operation has not been thoroughly done. But this conclusion may not be correct. The pad one feels may be a layer of granulation tissue kept in a septic condition by the discharge from an infected sinus. The following case illustrates this point:—

Adenoids.—A boy, aged 10½, had had "nasal catarrh" for some years, got easily tired, caught frequent colds, and sometimes lost his voice. Tonsils and adenoids efficiently removed 18 months previously; he seemed better for some months but then gradually the above-mentioned symptoms returned. Lavage of right antrum yielded a mass of muco-pus. Immediate improvement in symptoms ensued.

To ignore the possibility of a sinus infection in such a case may bring the operation for removal of adenoids into unreserved disrepute, and may also withhold urgently needed treatment for the patient. The similarity between the symptoms of sinusitis in children and those of adenoid hypertrophy was pointed out by Cleminson.[5]

Neuritis.—A married woman came to see me on Nov. 20th, 1922, with a history of "neuritis" in various parts of the body and frequent headaches. She diagnosed her own case quite correctly after reading an article in The Lancet[4] on sinus disease, although she had no obvious signs—in fact, her anterior nares showed no sign of pus or œdema. Her transillumination was clear, and only her own persistence induced me to proceed further and wash out her antra. Her antrum proved to be full of muco-pus. The condition cleared up rapidly; and so far the patient has had no headaches and very little "neuritis."

Arthritis.—A girl, aged 17, referred to me by Dr. J. Cohen, of Aldershot, gave a history of pain in the right knee-joint of three months' standing. No evident swelling but joint grated on movement. Nasal discharge for over a year. No subjective or objective fœtor, but her mother noticed a "sickly" odour from her handkerchiefs. Nose showed no visible pus, but transillumination was dark on right, and right antrum yielded muco-pus on proof puncture. After six washings combined with injection of argyrol her antrum was free from discharge. Her knee gradually improved concurrently with the treatment of her sinus and got quite well within a month.

I do not wish to give the impression that infection of the nasal sinuses is the only septic focus in the field of observation. It is only one of many. But it is apt to be forgotten, as I think the cases I have mentioned prove. It is a very important condition and fairly common, and the only safeguard against its being overlooked is routine examination. This should be done in all cases which may possibly be due to sinus disease. This paper is a plea for routine examination of the nasal sinuses.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OTOLOGY.

The first meeting of the section for the session was held on Nov. 3rd, under the presidency of Mr. **Sydney Scott**.

Changes in the Inner Ear in a Deaf Dog.

Mr. J. S. **Fraser** (Edinburgh) gave an interesting epidiascopic demonstration of the changes he had discovered in the inner ear of a dog which had been deaf from birth. He said they differed from those seen in dancing mice, which had also a deficient power of balancing. In the latter there were changes in the neuro-epithelium of the cochlea and the saccule. Alexander had held that an important cause of the changes in the cochlea was a deficiency in the vascular supply. Further study was required to discover the relationship of pigmentation to congenital deafness. The lesion in cases of congenital deafness was evidently in the region of the stria vascularis.

The **President** said the disease in these cases was apparently limited to the membranous labyrinth, and it was probably associated with failure of secretion of the stria vascularis. His own view had been that the stria vascularis corresponded to the analogue of the choroid plexus. He congratulated Mr. Fraser on the beauty of his slides.—Dr. **Albert Gray** (Glasgow) said he had heard from veterinary surgeons that deafness was much more common in dogs than in horses or cats. He had made sections from the ear of a deaf albino cat, and they were very similar to those shown by Mr. Fraser now from the dog. He thought the lesion was confined to the ductus cochlearis. The organ of Corti was flattened, and the tectorial membrane was rolled over it. He referred to the greater complexity of the human auditory apparatus in comparison with that of animals, and the difficulty of applying Mendelian principles to the human subject.—Prof. F. **Hobday**, F.R.C.V.S., remarked on the frequency with which congenital deafness was met with in the bull terrier, and veterinarians deplored the fact that they were powerless to remedy it. He hoped the work would be continued, and he considered this a further illustration of the need for coöperation between the medical man and the veterinary surgeon.

Otoliths in Fishes.

Mr. G. **Allen Frost** gave an exhaustive demonstration, by means of lantern slides, on the otoliths found in a large number of varieties of fishes.

In the discussion which followed, most of the speakers expressed the view that fishes could not hear ordinary sounds, but were remarkably susceptible to slight vibratory impulses, not only communicated direct to the water, but even to the contiguous bank. The **President** thought future observations in this connexion would be directed to the functions subserved by the otoliths, especially in view of the new work done in Holland in relation to the saccule and utricle and the various tonic reflexes.

Exhibition of Cases.

Sir **James Dundas-Grant** showed a patient whose pulsating tinnitus was greatly relieved by digital compression of the vertebral arteries. He pointed out the diagnostic value of the method, for in congestive conditions—i.e., at the climacteric—the compression of these arteries checked the trouble.

Mr. **Arthur H. Cheatle** showed a woman, aged 34, who had lupus of the lobule of the ear. There was no ulceration, and the skin was smooth. No sign of lupus or tubercle could be found elsewhere. He had removed the tumour and nodule in one piece, and sutured the skin.

Mr. T. B. **Layton** exhibited a youth, aged 19, who had suffered from meningitis, from which he recovered without the performance of trans-labyrinthine drainage. He had had severe influenza ten months ago, and for years there had been chronic ear disease, with discharge. In hospital he was so ill that it was thought he could not survive an operation. However, diseased bone was removed over the posterior cranial fossa, and a foul sloughing dura was exposed. The wound was packed, its edges left open, and lumbar puncture was carried out. No organisms were present in the fluid after 72 hours culture.

Dr. **DAN MCKENZIE** showed a patient on whom the radical mastoid operation was done without grafting or meatal plastic, according to the method of Bárány—i.e., operation was performed on the bone in the usual manner, without interference with the membranous meatus. In this patient there was complete healing without contraction of the meatus.—Mr. **L. COLLEDGE** thought it a retrograde step to treat cases in this way, because of the liability of débris and discharge collecting behind the meatus. He quoted cases which supported his remarks.—Mr. **H. TILLEY** agreed with Mr. Colledge, and said the surgery of these cases must be based on the best which could be done for 95 per cent. of the cases, rather than on what might happen to 5 per cent.—Dr. **P. WATSON-WILLIAMS** said that sometimes by not interfering with the tympanic wall one might retain to the patient a useful degree of hearing, whereas by a more complete operation a good deal of the hearing power might be lost.

Dr. **MCKENZIE** also showed a patient, a woman aged 60, whose cholesteatoma with fibrous changes produced a close simulation of malignant disease. An old-standing discharge was followed by recent facial paralysis, a hard semicircular mass could be felt under the skin and extended down in front of the ear as far as the tragus. The fibrous mass contained fibromatous material and gland tissue, and examination revealed no trace of malignancy.

Dr. **A. R. FRIEL** showed two patients whose chronic suppurative otitis media he had successfully treated by ionisation. The first patient, 16 years of age, had had aural discharge for many years, and it had persisted in spite of the application of drops. He brought about destruction of the granulations on the posterior wall by zinc electrolysis and nitrate of silver, followed by zinc ionisation of the cavity from which pus had been aspirated. This caused the discharge to cease. He described the technique in detail. His other case gave a history of aural discharge on one side for four years. There was attico-mastoid disease with a fœtid discharge, and cholesteatoma with polypus and granulations in the tympanum. Much the same treatment was carried out as in the last case, and the ear had now been dry for several months.—Dr. **WILLIAM HILL** said that although at first he felt sceptical as to whether Le Duc's method was likely to benefit such cases as Dr. Friel showed, he had been agreeably surprised at the results that gentleman had secured.

Mr. **H. RICHARDS** showed a woman, aged 27, the subject of herpes auris on the concha and floor of external auditory meatus. She had transient otorrhœa 16 years ago. Spontaneous gradual improvement set in. He also showed a case of cerebral abscess as a sequel to an otitis media which had completely healed. The abscess (encapsuled) was found to be in the temporo-sphenoidal lobe. The recovery was uninterrupted.

LIVERPOOL MEDICAL INSTITUTION.

A MEETING was held on Oct. 25th, with Dr. **J. HILL ABRAM**, the President, in the chair, when Dr. **JOHN HAY** and Dr. **H. WALLACE JONES** contributed a note on

Dextrocardia.

Dr. Jones said that the term dextrocardia in its widest sense was applied to a heart beating in a more or less permanent manner in the right half of the thorax. The condition had been known from ancient times, but the modern application of X rays and electro-cardiographs had made the diagnosis one of comparative ease. He classified the varieties as follows:—Inversions: "Mirror image" of the heart. 1. Complete. 2. Incomplete—(*a*) transposition of viscera with heart in the normal position; (*b*) complete inversion of the thoracic organs, and a liver situated in the middle line; and (*c*) inversion of the heart only. Dextro-versions: Heart displaced to the right without inversion of the cavities. (*a*) Occurred during fœtal life; and (*b*) acquired since birth. He showed records of four cases—two cases of complete transposition with inversion of the main deflections in lead 1 of the electro-cardiograph and two cases of acquired dextrocardia, not due to any obvious cause, with normal electro-cardiograph records.

Dr. **T. W. WADSWORTH** read a note on a case of

Syringomyelia.

He said that the cord was obtained from a patient in the Walton institution, who died, aged 51, from a pontine hæmorrhage. There was an extensive gliosis of the central region of the cord extending from the upper cervical cord to the lumbar region. In the cervical and mid-dorsal regions there were large cavities near the central canal, not lined by ependyma. He had manifested symptoms of syringomyelia for over 20 years, and carried on his occupation as a labourer up to three years of the time of his death. The hands were claw-like, with many scars, due to old painless injuries and burns—some of the latter were recent; tactile sensation was almost normal, but there was loss of sensation to heat, cold, and pain, especially of the hand. There was well-marked scoliosis and spasticity of the legs; towards the end he became ataxic. No arthropathy, perforating ulcer, or nystagmus was present.

Dr. **A. C. RANSOME** read a paper on the treatment of

Late Neuro-syphilis and Disseminated Sclerosis.

He gave the results of his treatment of these two classes of organic nervous diseases in Manor Hill Neurological Hospital. Cases of tabes, tabo-paresis, and early G.P.I. were divided into two groups for treatment according to the condition of the cerebro-spinal fluid. Those with a high cell count, a tabo-paretic gold curve, an excess of globulin, and a positive W.R. were given intrathecal injection of re-enforced salvarsanised serum, while those with a luetic gold curve, a lower cell count, and globulin excess and positive W.R. were given neokharsivan or oxycyanide of mercury by intravenous injection. Both groups received the same after-treatment of mercury and pot. iod. by mouth. The clinical results of treatment agreed very closely with the effects on the condition of the cerebro-spinal fluid. In this the reduction of lymphocytes, of globulin, and the flattening out of the gold curve were very marked, and were accompanied by the cessation of pains and crises, by increased control of sphincters, and in some cases by ability to return to work. Slides were shown illustrating the condition of cases before treatment, after treatment, and after an interval of a year. Thirteen cases treated by intrathecal salvarsanised serum showed 8 improved, 3 no change, 1 worse, 1 transferred. Twenty-six cases treated by intravenous neokharsivan and oxycyanide of mercury showed 9 improved, 11 no change, 6 left hospital. Thus intrathecal treatment appeared to be more efficacious than intravenous, in spite of the fact that the former group were more advanced clinically and pathologically. Thirty-six cases of disseminated sclerosis were treated by intravenous injection of silver salvarsan on the assumption that the disease is caused by a specific spirochæte distinct from that causing syphilis. The results were 14 improved, 10 no change (including 5 only recently treated), 9 left hospital, 3 died of intercurrent disease. While allowing for errors of observation, possible remissions, for the concomitant effects of massage, exercises, healthy surroundings, &c., Dr. Ransome considered the result of this treatment as encouraging and worthy of further trial.

Dr. **DOUGLAS BIGLAND** thought that too much weight had been placed upon the colloid gold reaction, which was notoriously unreliable on occasions. This test was most useful when it agreed exactly with the other spinal fluid reactions. Good results might be obtained from intrathecal therapy, but he had obtained just as good effects with drugs administered by the intravenous and oral route. He considered that when two methods of treatment give approximately equal results, the simpler, the less expensive, the less painful, and the more generally applicable one should be used in preference to the one not having these advantages. The effects of mercury, especially when administered by inunction, were little short of marvellous in certain forms of neuro-syphilis.

Dr. **BAKER YOUNG** stated that the advocates of intrathecal therapy claimed that advanced cases of neuro-syphilis could be benefited, and in some cases be enabled to return to work; in others the improvement would allow them to resume home life. Cases in which a paretic curve with the gold sol is persistent in spite of treatment were invariably fatal and particularly prone to suicide. Intrathecal therapy was indicated in early cases which showed an abnormal fluid. J. A. Fordyce had stated that at least 25 per cent. showed changes even after intensive treatment intravenously. If these cases were then treated intrathecally the fluid became normal, and the natural inference was that a potential tabetic or paretic finale had been avoided. Dr. Young congratulated Dr. Ransome on the excellent results of his cases.

ROYAL MEDICO-CHIRURGICAL SOCIETY OF GLASGOW.

A MEETING was held on Oct. 19th, Dr. A. MAITLAND RAMSAY, the President, being in the chair.

Discussion on Pathology, Symptomatology, and Treatment of Disseminated Sclerosis.

Dr. **DOUGLAS ADAMS**, in an opening paper, briefly reviewed the literature of disseminated sclerosis, and referred more particularly to recent results obtained in an investigation which is being carried out in the pathological department of the University and Western Infirmary of Glasgow in collaboration with Drs. E. M. Dunlop, J. W. S. Blacklock, and J. A. A. W. McCluskie. In a considerable number of cases paralysis had been transmitted to rabbits by the injection of blood or spinal fluid from patients suffering from the disease, and had been passed from rabbit to rabbit both by direct inoculation and by passage through culture. Spirochætes were found in the organs of seven of the inoculated animals both by dark ground examination and by staining, though examination of the cultures employed yielded negative results. These results were regarded as confirming the view that the disease is infective in origin. Emphasis was laid on the necessity for early diagnosis, and in this connexion the value of the colloidal gold reaction was urged. The results of intensive anti-specific treatment of 50 cases were referred to. In many cases considerable clinical improvement had been noted, and this had coincided with a modification of the colloidal gold curve in a direction towards negative. In the majority of cases the subsequent absolute or relative freedom from relapses during a period of three years was striking. The investigation was being continued under a grant from the Medical Research Council.

Dr. **BLACKLOCK** described in more detail the various experiments performed, and said that when blood or spinal fluid from cases of disseminated sclerosis had been inoculated directly into rabbits, about one-third of the animals developed nervous symptoms. An emulsion of the central nervous system of these paralysed animals produced nervous symptoms in a proportion of cases on inoculation into other animals either directly or after passage through Noguchi's medium. No nervous symptoms had been noted in over 200 normal control animals kept under observation for periods varying from four months to over a year, nor had paralyses developed in animals inoculated with various protein substances. He considered it probable that a virus was present in the blood and cerebro-spinal fluid of these patients which was capable of existing in the central nervous system and of producing paralysis in a proportion of the animals inoculated. The pathological lesions that had been noted in the central nervous system of the inoculated animals were: (1) Cellular infiltration, chiefly under the ependyma of the ventricles. (2) Degeneration of nerve tracts—this latter had been observed only in one animal that had lived for over a year after the onset of paralysis. The other animals that had shown nervous symptoms had lived for too short a time after the onset of such symptoms to allow definite pathological changes to occur. (3) Petechial hæmorrhages. (4) Multiple lesions of the nature of softening.

Dr. **BROWNLOW RIDDELL** referred to the frequent occurrence of slight and transient eye symptoms in the early stages of the disease, and urged the importance of a critical interpretation of such symptoms in a case presenting no other apparent clinical feature. The surprisingly slight attention paid by the average patient to transient eye symptoms, with the speedy recovery therefrom, and the absence of any other sign or symptom, combined to present a clinical picture often under-estimated or attributed to a functional, hysterical, or digestive origin. Dr. Riddell then considered in detail various symptoms, including diplopia, acute retro-bulbar neuritis, nystagmus, and optic atrophy, and described a number of illustrative cases.

Prof. C. H. **BROWNING**, in commenting on the results of the experimental work, said that the small proportion of successful transmissions was not surprising in view of the insusceptibility of both man and animals to the disease. He emphasised the fact that the virus persisted in the culture media which had been inoculated with blood from cases and kept over long periods in the incubator, and was inclined to the opinion that the pathogenic agent was a living organism or the product thereof. He then referred to the value of the colloidal gold reaction as a means of early diagnosis and of controlling the results of treatment.

Prof. **ROBERT MUIR**, in referring to the pathological and histological changes in the disease, said that, while very definite, they yet presented certain peculiar characteristics. The essential features at an early stage were (*a*) a disappearance of the myelin sheaths, (*b*) a persistence of the axis cylinders, and (*c*) an absence of Wallerian degeneration. These changes occurred in patches which were often sharply cut off, as though by a knife, from the surrounding healthy tissues. The process was peculiar and quite unlike a true sclerosis. The colloidal gold reaction in the cerebro-spinal fluid he considered would mark a real advance if completely established, and would prove of great assistance in controlling treatment. Referring to the ætiology he was of the opinion that, while a great many facts supported the infective theory, the state of the experimental work was as yet too uncertain for complete proof—while hopeful, it was not conclusive.

BATH CLINICAL SOCIETY.

A MEETING was held recently with Dr. W. P. KENNEDY, the President, in the chair.

Dr. R. G. **GORDON** read a paper on the Difficult Child. He dealt with the types of difficult behaviour in children both in infancy and in later life. The importance of the attitude of the parent was emphasised. The causes of failure of integration of the personality leading to difficulty in adaptation to life were classified under three headings in relation to the proper functioning of the cortex: (1) Failure of development—mental deficiency; (2) disease of the cortex, specially congenital syphilis and epidemic encephalitis; (3) inherent lack of proportion in dispositions leading to psychological maladaptations. Illustrative cases were quoted.

Dr. R. **WATERHOUSE**, Mr. A. L. **FULLER**, and Mr. J. S. **LEVIS** showed specimens.

Reviews and Notices of Books.

THE MECHANISM AND PHYSIOLOGY OF SEX DETERMINATION.

By DR. RICHARD GOLDSCHMIDT. Translated by Prof. W. J. DAKIN. London: Methuen and Co. 1923. With 113 figures. Pp. 259. 21*s.*

SEX is an accident, the result of the immutable laws of chance. To the world at large it does not matter at all which individuals are male and which are female, so long as there are approximately the same number—or an equivalent functional number—of each. But it matters so much to the individual, or so he or she thinks, that the problem of sex determination has always been one of absorbing interest. This massive and scholarly book discusses the whole question on the basis of sex as a Mendelian character, and in it the author weaves together a fascinating account of cytology combined with experiment, pointing out very clearly how the two lines of research have dovetailed into one another. After an account of the normal behaviour of the sex-chromosomes, and a discussion of the intersexes in moths which he has himself studied to such good purpose, the author gives a clear summary of the main position.

> Every developing individual of a bisexual organism contains the substances whose action can call forth the one or the other sex. A particular mechanism, disclosed by Mendelian experiment and visible in the sex chromosomes, distributes these substances to the offspring in such a manner that half the offspring receive the substances in one proportion whilst the rest receive them in another, and so that either the male or the female substances are present in excess quantity. These substances act like enzymes—proportionally to their concentration. The quantitative difference of the substances in the two groups of individuals is automatically responsible for either the male or female enzyme completing the determining reaction first. This reaction is the production of specific hormones of sexual differentiation.

There is one pathological relation in which the author's conception that each factor is a dose which may diminish or be exhausted in the course of the individual's life is specially suggestive. A hen is female because its femaleness predominates, not because it has no maleness, and its femaleness may, as it were, wear out. It may then become an anatomical, and even a functional, cock. The magnificent studies of Miss Stye on the inheritance of cancer in mice (summarised in a convenient form by Prof. H. G. Wells in the *Journal of the American Medical Association*, vol. lxxxi. (1923), pp. 1017, 1103) show that the tendency to develop cancer behaves as a Mendelian recessive character. And the age-incidence of the disease suggests that we may here have another example of the quantitative efficacy in time of a heritable quality such as explains the changes of sex in fowls and moths.

The later chapters deal with various special problems—the inheritance of secondary characters, hermaphroditism, parthenogenesis, numerical sex ratios and sex determination in man. There is no recipe for getting a boy, and those who have no particular knowledge of the modern development of the subject will not find the book very easy reading. But it is worth some pretty stiff study.

PSYCHOLOGY.

The Psychology of Reasoning. By EUGENIO RIGNANO, Professor of Philosophy in the University of Pavia. Authorised translation by WINIFRED A. HOLL. London: Kegan Paul. 1923. Pp. 395. 14*s.*

PROF. RIGNANO's aim is to show that reasoning depends upon two primordial activities, the intellectual and the affective. The first consists in mnemonic evocations of perceptions and images of the past; the second appears as aspirations towards a certain end, whither the reasoning is directed. Retention and recall of memories are easily explained thus: "The simple conception of specific mnemonic accumulation, that is to say, of specific nervous energy which passes alternately from the actual to the potential state and vice versa, is sufficient to account completely for the phenomena of evocation" (p. 374). But why formulate this conception, which is simple only through the impossibility of examining the supposed physical mechanism? The satisfaction derived from its contemplation is an unhealthy substitute for a confession of ignorance. It is really offered as an alternative to the theory of the unconscious, but is lacking in the pragmatic justification which the latter possesses. The author criticises this theory on a priori grounds; he has plainly not attempted to employ those practical methods, unknown to the older academic psychology, which necessitate the theory of the unconscious as a convenient means of summing up the results obtained. The author shows a thorough grasp of the views enunciated by recognised authorities, and brings his own ideas into relation with general theory. But the book reminds us that psychology was till recently little more than philosophical speculation, and it is disappointing to the reader who seeks the possibility of applying psychology to the actualities of life.

The Unconscious Mind. By S. HERBERT, M.D., M.R.C.S., L.R.C.P. London: A. and C. Black. 1923. Pp. 230. 6*s.*

THIS book covers within a small space the greater part of psycho-analytical theory. Except for some illustrations from the author's own experience it is a compilation from well-known sources, with occasional criticism. It will prove useful to anyone who wishes to obtain a general idea of the ramifications of Freud's theories and is willing to believe them; but it will carry little conviction to those for whom belief is difficult.

THE PRACTICAL MEDICINE SERIES.

Vol. I. *General Medicine.* Edited by GEORGE H. WEAVER, M.D., LAWRENCE BROWN, M.D., ROBERT B. PREBLE, A.M., M.D., BERTRAM W. SIPPY, M.D., and RALPH C. BROWN, B.S., M.D. Series 1923. Chicago: The Year Book Publishers. Pp. 678.

THE multiplicity of medical literature at the present day makes it impossible even for the research worker to keep abreast of the advances of medical knowledge except in a very narrow field. Epitomes of advances must accordingly be of ever-increasing value to all members of the profession. The present volume deserves a wide circulation; its contents are largely derived from American sources, and if this deprives it of completeness it is at the same time a further tribute to the excellence and magnitude of the clinical and laboratory research which is in progress in the United States. Full references are given. No medical man who reads this book can fail to secure from it both interest and instruction. The volume is compact, and is enriched by numerous illustrations reproduced from the original articles quoted.

A PRÉCIS OF PATHOLOGICAL MEDICINE.

Maladies de l'appareil respiratoire. By FERNAND BEZANÇON and S. I. DE JONG. Paris: Masson et Cie. 1923. Pp. 566. Fr.20.

TEXT-BOOKS seem to be getting smaller as knowledge increases, an observation which suggests that the concentration of knowledge in the older text-books was not very high. The present volume is characteristic of the modern tendency. There are, indeed, as many as 566 pages, but the print being large and the pages small, the words are comparatively few. Thanks to an elaborate table of contents and numerous sub-headings in each chapter, the reader can speedily find any subject he is particularly interested in. The work is a study of the respiratory structures from the nose and larynx to the diaphragm. Under each heading, such as pleurisy, there are sub-headings dealing with physical signs, diagnosis, and treatment, all being arranged in a logical sequence. Scattered throughout the book are innumerable hints and "tips," such as the experienced clinician, rather than the physician who spends most of his time in writing and teaching, is in a position to give. For example, we are told that the pleural effusion due to disease of the heart and kidneys is nearly always on the right side, and that the interlobar effusion is generally due to the pneumococcus. Some parts of this book are much better than others. The short section dealing with tuberculin treatment, for example, is unsatisfactory. The authors would, no doubt, be the first to admit this, and they could well justify themselves by the defence that the position of tuberculin treatment is itself unsatisfactory at present, and that the author who discussed it in a clear-cut, dogmatic fashion would be lacking in truthfulness. There are numerous illustrations, of which the line-drawings are undoubtedly the best. The reproductions of certain skiagrams are poor; they may possibly be of interest to radiologists, but they are not easily interpreted by the student or general practitioner.

On the whole this work fulfils its aim—that of being a handy vade-mecum.

JOURNALS.

QUARTERLY JOURNAL OF MEDICINE.—The October number contains the following articles: Paraplegia and Cauda Equina Symptoms in Lymphogranulomatosis Maligna (Hodgkin's Disease), by F. Parkes Weber. A case of Hodgkin's disease is described which came under the author's care. Ten months before death lumbar pain was noticed, which was later followed by pain in the right thigh and paraplegia. Post-mortem examination showed that these nervous symptoms were due to a lymphogranulomatous mass inside the vertebral canal, attached to the outside of the dura mater over the end of the spinal cord and the cauda equina. A periosteal growth of a similar nature was present on both outer sides of the vertebral centra near the diaphragm. A description is also given of certain other cases from the literature dealing with cord pressure symptoms in Hodgkin's disease.—Erythrœdema Polyneuritis (the so-called "Pink Disease"), by Donald Paterson and J. Godwin Greenfield. Swift, in 1914, first gave the name erythrœdema to this disease of children, many cases of which have subsequently been recorded in Australia and America. The authors, who have observed five cases, give here a clinical account of the disease and produce fresh evidence as to its essential nature, based on the post-mortem examination of the nervous system. A coloured plate shows the characteristic appearance of one of the patients, whose hands, feet, cheeks, and nose are red and swollen, but do not pit on pressure. There are muscular hypotonia and loss of deep reflexes but no pyrexia. The ætiology is unknown, but it does not appear to be a food-deficiency disease, and is probably due to infection. Peripheral neuritis and chronic inflammatory changes in the spinal cord and nerve roots are found after death. On the whole, the prognosis is good and the tendency is towards a complete recovery.—The Reaction to Adrenalin in Man, by D. Murray Lyon. Certain reactions produced by the subcutaneous injection of 0·5–1 c.cm. adrenalin chloride were studied in 35 subjects. Attention was directed to the results following the administration of the drug as judged by local and general reactions, and alterations in the blood pressure, pulse-rate, basal metabolism, respiratory quotient, respiratory rate and depth, and blood- and urine-sugar content. The subjects of the investigation included normal individuals, and sufferers from diabetes mellitus, hyperthyroidism, hypothyroidism, and asthma. Whereas in every case the systolic blood pressure showed some rise, the diastolic reading was usually lowered. The metabolic rate was invariably increased, on the average by 20 to 40 per cent. The blood-sugar was increased, but this rise occurs more slowly than is the case with the other reactions, and takes longer to pass away. A considerable proportion of the patients showed a transitory glycosuria. No changes characteristic of the diseases investigated were discovered.—The Lævulose Test for Liver Efficiency and an Investigation of the Hepatic Condition in Pregnancy, by Kenneth H. Tallerman. The author regards the lævulose test for liver efficiency as a most useful one. Observations were made upon a series of adult males who showed no signs of hepatic disease, and their blood-sugar curves were determined after administering 30 to 50 g. of lævulose by the mouth, according to the weight of the subject. The normal renal threshold for lævulose was found to be lower than for glucose. Women in the seventh month of pregnancy were also investigated. They were selected as normal cases, showing no albuminuria and no toxic symptoms. The lævulose test did not point to any impairment of liver function, but the renal threshold for lævulose in pregnancy was found to be practically non-existent.—Visceral Pain in the Upper Alimentary Tract, by W. W. Payne and E. P. Poulton. An ingenious apparatus was used to register changes in pressure in the œsophagus, stomach, duodenum, and jejunum. It consists of a small rubber bag containing water which the patient swallows and which is connected with a water manometer. With the bag in the œsophagus a wave of contraction followed by a wave of relaxation was observed on swallowing, the rate of their progress being about one inch a second. Peristaltic movement of the œsophagus is also associated with the sensation of "heartburn" felt beneath the sternum. Confirmatory evidence of Verdon's view that angina pectoris is caused by distension of the stomach was not obtained, and in one case the pain was abolished by sucking air into the stomach. In another instance angina was not associated with œsophageal movements. In gastroptosis the pressure in the stomach was found to be higher in its upper than in its lower part, and this difference may be abolished by wearing a belt. Pain in the upper abdominal region may be associated with movements of the pylorus, duodenum, or jejunum, but the exact relation of the pain to these movements was not fully determined.—Liver Atrophy, by James Miller and Andrew Rutherford. This article opens with a historical account of the views held as to the varieties of liver atrophy, and this is followed by a description of 16 cases, of which clinical and pathological notes are given. These fall into three groups: (1) Acute, corresponding with the old "acute yellow atrophy"; (2) subacute, in which, in addition to destruction of liver parenchyma, there is vascular and inflammatory cell reaction and early fibrosis; and (3) "Multiple nodular hyperplasia": here adenomatous nodules of new liver tissue are found. Five plates are included illustrating the macroscopical and microscopical appearances of the liver in various cases.—Generalised Myositis Fibrosa, with the Report of a Case, by J. A. G. Burton, John Cowan, and Hugh Miller. This is a rare disease, of which only five cases have been previously recorded. The example here described was a woman of 25, who gradually suffered from stiffness in the arms and legs, which increased to such a degree as to render her completely helpless. The muscles had the characteristic firm feeling, suggesting a sandbag or piece of wood. The electrical reactions showed no R.D., but the deep reflexes were absent. A small piece of muscle was excised, and on microscopical examination degeneration of the muscle elements was seen. The patient, despite relapses, improved very considerably with massage and electrical treatment. The appearances of the muscle are well shown in the accompanying plate.

THE TROPICAL DISEASES BULLETIN for October contains a review of recent studies on malaria by Clayton Lane.—A large section on medical zoology is reviewed by A. Alcock.—Undulant fever, dengue, pappataci, unknown fevers, Rocky Mountain spotted fevers, Japanese river fever, Oroya fever, and Verruga peruviana are summarised by P. W. Bassett-Smith. Beri-beri and scurvy are also dealt with by the same author.—Leprosy is reviewed by Leonard Rogers; yaws and a number of miscellaneous subjects by A. G. Bagshawe.

Reports and Analytical Records.

NEW ZEALAND IMPERIAL BEE HONEY.

(MARKETED BY THE NEW ZEALAND HONEY PRODUCERS ASSOCIATION, LTD., AUCKLAND. IMPORTED BY MESSRS. A. T. MILLS & CO., LTD., TOOLEY-STREET, LONDON, S.E. 1.)

When analysed this honey was found to have the composition :—

Dextrose	39·4 per cent.
Lævulose	35·8 ,, ,,
Water	16·5 ,, ,,
Cane sugar	1·6 ,, ,,
Ash	0·16 ,, ,,
Acidity (formic acid)	0·01 ,, ,,
Wax, protein, and undetermined matter	6·53 ,, ,,

Microscopical examination showed the presence of clover and heather pollen grains.

This honey is of a mild and pleasant flavour, which cannot be said of all Australasian honeys. It is a pure honey containing no admixture of invert sugar or dextrin-glucose and no preservatives. The makers state that at no time during extraction or packing is it touched by hand. It should prove a useful addition to the limited supply of home-produced honey.

MOUNTAIN DEW SCOTCH WHISKY.

(EDWIN YOUNG & CO., GLASGOW, LONDON, AND LIVERPOOL.)

This well-known brand of whisky, which claims to be "the real original as sold prior to 1834," when analysed gave the following results :—

Proof spirit	70·15 per cent.
Equivalent to	29·85 U.P.
Absolute alcohol by volume	40·1 per cent.
Total extractives	0·15 ,, ,,
Ash (mineral matter)	0·01 ,, ,,
Secondary constituents expressed as parts per 100,000 of absolute alcohol—	
Volatile acidity (as acetic)	19·4
Fixed acidity	Nil.
Furfural	0·6
Esters (as ethyl acetate)	44
Aldehydes	22·5

Considerations based on these analytical figures point to this whisky being a thoroughly well matured and carefully made spirit. The flavour and aroma are agreeable and characteristic of a high-grade Scotch whisky.

SOFTENING OF HARD WATER.

A sample of water received on Oct. 25th from a physician at Scarborough, when analysed was found to contain :—

Total solids	26	parts per	100,000
Total hardness (soap test)	20	,, ,,	,,
Permanent hardness	9	,, ,,	,,
Temporary ,,	11	,, ,,	,,

To soften every 100 gallons of this water 2 oz. of a mixture consisting of 4 lb. freshly slaked and powdered pure lime and 3 lb. of anhydrous sodium carbonate should be added. The 2 oz. should be stirred up with about a quart of the water and the resulting cream thoroughly stirred into the 100 gallons. The whole should be allowed to stand until clear (not less than 12 hours) when the upper portion may be drawn off for use.

LLATAI FINE TOILET SOAP.

(LLATAI TOILET CO., 122, QUEEN-STREET, CARDIFF.)

This soap, which is made up into heart-shaped tablets, is stated by the manufacturers to be prepared from tallow and American resin. When analysed it was found to have the composition :—

Water	12 per cent.
Fatty and resin acids	76·5 ,, ,,
Total ash	17·65 ,, ,,
Free caustic alkali	nil
Alkali (Na_2O) combined as sodium carbonate	0·1 ,, ,,
Alkali (Na_2O) combined as soap	9·44 ,, ,,
Resin acids	Present

The moisture in this soap is very low, which makes it unusually economical to use. Another point in its favour is the absence of free alkali. It is pleasantly, but not excessively, scented with woodruff, and lathers well.

New Inventions.

APPARATUS FOR THE ADMINISTRATION OF WARMED ETHER VAPOURS.

In this apparatus the air from the bellows, instead of passing direct through the ether, is first heated by being passed through a loop of copper tubing, which is placed within the spiral coil immersed in hot water and contained in the large thermos flask. This increases the evaporation of the ether, thereby producing a high percentage of ether vapour, and a steady and uniform strength. The heated air passes by a small tube into the ether bottle and into a large metal cylinder, so that the cylinder which goes to the bottom of the ether bottle can slide up and down over the small tube, and this can be made adaptable, if necessary, to a varying size of bottle. The cylinder, which is closed at the lower end, has a number of small holes through which the air passes into the ether. This results in the air-bubbles, instead of being large, as produced by a single tube, being broken up into a number of smaller ones. Thus the air becomes more thoroughly saturated with ether. The apparatus has the following advantages: 1. A very strong ether vapour can be produced, resulting in a deep anæsthesia, so that very little chloroform need be used, often none at all. 2. The thermos flask being a large one, it is only necessary to change the water in exceptionally long operations. 3. No freezing takes place in any part of the apparatus. 4. By sliding up the cylinder, a weak ether vapour can be procured and a mixture of chloroform can be employed. 5. By removing the cylinder, hot air passes over the ether, so that with the addition of a manometer it can be used as a simple form of apparatus for intra-tracheal use. 6. The anæsthetic vapour or vapours and air are thoroughly heated. 7. The spiral tube in thermos flask is an excellent device for heating nitrous oxide, oxygen, and so forth. The apparatus can be used for warmed oxygen and alcohol inhalations. I have had the apparatus in use for some years in South Africa and found it of great value.

Public Health Services.

Ministry of Health: The General Practitioner Service.

The section of the annual report [1] of the Chief Medical Officer of the Ministry of Health for 1922 dealing with service under the Insurance Act shows how the work of the men in general practice is recognised now as part of the Ministry's activities. Those who undertake insurance work form a definite part of the "great national organisation for the control of disease and the prevention of premature death," to quote Sir George Newman's words. It is well that this should be recognised both by the public and the medical profession.

Both the value and the potentiality of the service is shown by the figures quoted in the report. There are approximately 12½ million insured persons on the practitioners' lists, and rather more than 12,500 practitioners under contract to give the necessary treatment in the form of medical benefit, the average number for which each practitioner is responsible being therefore about 1000. As an indication of the amount of work involved in the year under review it is estimated that 6 million persons received treatment and about 44 million attendances were made. The small number of cases dealt with by the disciplinary committees and tribunals affords some index of the standard of efficiency and conscientiousness which has been reached, and the general satisfaction given; with such evidence, positive and negative, to rely upon the assertions that the medical benefit clauses have wholly failed in their promise and objects need not too much depress us. Lapses, however, do not go unnoticed; 520 reports of investigations into complaints were received in 1922, and in 84 cases, the complaints being substantiated, fines were inflicted. Seven representations were made to the Minister that the practitioner should be removed from the panel. Of these cases, five were investigated by inquiry committees and two of the practitioners were removed from the list. The three remaining practitioners were not removed, but in one case a sum of £100 was withheld from the practitioner's remuneration. In two cases an inquiry was not held, one practitioner's name having been removed from the Medical Register, and the other having given satisfactory assurances for the future ordering of his practice.

The work of the Regional Medical Staff is reported upon in favourable terms. The services of the regional officers have been sought in a greater number of cases. The references of cases of doubtful incapacity for work amounted to 113,685 in 1922 as compared with 69,543 references in 1921. In addition, 1253 consultation cases were referred, and of these 802 were examined. The staff also examined 382 persons claiming old age pensions under the Blind Persons Act of 1920. It may be remembered that it is also incumbent on the regional staff to inspect the medical records and the register of dangerous drugs required to be kept by all dispensing doctors under the Home Office Regulations of 1920. The work of the staff and the practitioners will be more effective when the additional facilities for diagnosis are in operation next year, and the help which the regional medical officers could give to insurance practitioners would be considerably greater if the provision of hospital beds were materially increased.

The attention of general practitioners may be specially called to the concluding observations of Sir George Newman in which he emphasises the importance of early diagnosis. "We are liable to forget that the largest burden of our invalidity, and the chief contribution to premature mortality, are due to the neglect of the comparatively minor or incipient forms of sickness and ill-health. . . . They lay the foundations of the major diseases. . . . This is one of the great spheres where the medical practitioner coöperates with the Public Health Service."

MENTAL HOSPITALS SERVICE.

The recently published reports of three mental hospitals [2] in England, Northern Ireland, and India respectively present several features of interest. Each report is something more than a formal record of the year's activities, and a quantity of information is given which enables the reader to appraise the work of the institutions and the difficulties which have been encountered.

At Hellingly a visiting dentist and surgeon have been appointed, and during the present year it is hoped to add an ophthalmic surgeon to the consulting staff and an operating theatre to the equipment of the hospital. A long list of operations performed during the year under review indicates the future value of this improvement. An out-patient department under the direction of the medical superintendent has been opened in Eastbourne, and the number of patients attending it has steadily increased. Dysentery has unfortunately been more or less endemic in the hospital throughout the year, and 14 deaths occurred from this disease. It is interesting to note that treatment with a stock vaccine (Shiga and Flexner), as recommended by the Board of Control, produced no appreciable effect, but the results of treatment with an antidysenteric serum were "most satisfactory, patients reacting immediately." Good results were also obtained with luminal in epileptic cases, the number of fits being greatly reduced, but no improvement in the mental condition occurred, and withdrawal of the drug was apt to be followed by status epilepticus.

The Belfast District Asylum, which is constructed on the "Villa Colony" system, has undertaken the erection of further new buildings, including "reception villas" for new cases. It has now been decided to combine these in a single building for the treatment of recent cases, male and female, so situated that all contact with the chronic insane will be avoided. The diet of the patients has been amplified, chiefly by the addition of fresh garden produce in the form of salads. No less than 81 per cent. of the patients are usefully employed. A "tuck-shop" has been installed in the grounds, where patients and their friends may buy confectionery, fruit, and tobacco. Parole has been granted to a large number of patients. On the recent retirement of the matron and the head attendant these positions were combined as a single office, and the newly appointed matron has control of both female and male nursing staff. This report, as usual, is attractively illustrated with photographs of the estate and of the wards.

The European Mental Hospital at Ranchi, which accommodates about 150 patients, has recently been transferred by the Indian Government to the control of a Board of Trustees. It has also been "affiliated to the University of London in connexion with the examination for the Diploma in Psychological Medicine." Its name has been changed from "Asylum" to "Mental Hospital" under the provisions of the Indian Lunacy (Amendment) Act, 1922, and this change is regarded as signalising the first step towards the hospitalisation of the Indian asylums. The medical superintendent, in a long report of great interest, alludes to some of the difficulties which attend the treatment of the insane in India. Of these the nursing problem appears the greatest. No mental nurses in India hold qualifications, for there are none to be obtained in that country; their training is often inadequate, and "in existing circumstances—i.e., of inadequate remuneration and work under very trying conditions—persons who are willing to engage in the care of the insane do not possess, as a rule, the education that is otherwise desirable."

[2] Annual Report of the East Sussex County Mental Hospital, Hellingly. Annual Report of the Belfast District Asylum. Report of the European Mental Hospital at Ranchi (India).

There is also a lack of any organisation in the country to deal with mental prophylaxis and the after-care of discharged patients. Among the minor difficulties and abuses may be noted the confinement of civil patients in jail for purposes of observation, and the conveying of female patients to the hospital by male police officers. Certification papers are often faulty, and the medical superintendent has suggested an amendment to the existing law to provide for the detention of improperly certified patients pending further steps, but this proposal has not been adopted. The War Office has recently arranged for the free conveyance of mentally afflicted members of families of Government officers to the United Kingdom. Accommodation has been set aside for this purpose in all transports. Difficulties, however, have arisen; "great difficulties are placed in the way of even quite quiet mental cases taking air and exercise on deck" and "in the case of male patients the absurd prohibition to shave or be shaved appears still in force." Finally, under the existing English law, such patients have to be re-certified in the United Kingdom. As regards the work of the hospital, stress is laid on hydrotherapy, which is conducted in the patient's own room in order to eliminate disturbance and enhance the sedative effect, and on occupation therapy, for which a work master and mistress are badly needed. Organotherapy (with extracts of ovary, thyroid, and pituitary) has yielded "most discouraging results." Parole is granted to a large number of cases with no untoward results hitherto. Various changes are contemplated, including the abolition of male attendants and their replacement by female nurses. There is altogether much evidence that lunacy administration is undergoing changes more numerous and rapid in India than in England.

SCHOOL MEDICAL SERVICE.

Liverpool.

The coöperation between the School Medical Service and the University in Liverpool has resulted in an important extension of facilities for dental training. Fourth and fifth year students are allowed a regular attendance at the school clinic for a period of one or two months at a time, during which they are under the personal supervision of the school dentists, and have excellent opportunity for increasing their experience of dental work amongst school-children. At present, owing to the cost of equipment, only four or five students attend simultaneously, but it is hoped shortly to accommodate at least 12 students at a time. The advantages gained by the university and the education committee are mutual and well balanced, as the amount of work undertaken in 1922 shows a considerable increase over that of the previous year—6828 against 5859 cases—although the arrangements had only been in operation for about three months. The increase in the amount of dental work undertaken in Liverpool is enormous. The figures have risen steadily from 13,481 in 1919 to 29,772 in 1922. "The presence of active dental caries was noted in about 78 per cent. of the children of clinic age examined, this being the most prevalent defect amongst school-children for which the committee are required to make provision. As years go on and treatment is carried out over a wider area, the proportion will no doubt considerably diminish, but the problem will always be an expensive one to cope with."

Dr. E. W. Hope, the medical officer, reports that for years past in Liverpool sporadic cases of what was considered to be trachoma, a contagious inflammation of the lining membrane of the eyelids and front of the eye, have been discovered chiefly in the Kirkdale district, but not in sufficient numbers to require special action to be taken. During 1922, however, a number of suspicious cases were reported from schools in different centres of the city, and on these being sent to the committee's oculist for examination and report, it was found that 28 out of 32 were definite cases of trachoma, the remaining four being cases of follicular conjunctivitis. Only two girls were affected, and the majority of the children were between 12 and 13 years of age. At the end of four months only four were cured. During the year 115,835 children were examined, 73,484 of these being elementary school-children, and only 306 cases of malnutrition were found. This is equal to 0·87 per cent. and compares with 1·3 per cent. in 1921 and 1920. In 1913, the year before the war, this figure stood at over 7 per cent., and in 1914 was 5 per cent., so that the recent figures may be considered small by comparison.

The report of the inspector of physical training makes interesting reading, and it is good to know that the scheme of organising games for boys and girls in the parks during the summer holidays is being continued. The parks are provided with paid "play leaders," and games apparatus consisting of cricket bats, balls of various kinds, skipping ropes, net-ball outfits, rounder bats and balls, in addition to numerous other necessary appliances are provided by the committee. This apparatus is stored in lock-up huts which were erected in the parks in 1920. The scheme is one which should be copied far and wide.

Manchester.

In Manchester the staff has been reduced by two nurses and three clerks, and Dr. Brown Ritchie considers the staffing in all departments below the amount necessary for satisfactory work. He draws the committee's attention to the fact that a considerable amount of clerical work, which is bound to increase, is involved in work not strictly medical, such as the work connected with school attendance. Such work as this cannot be delayed or set aside as promptness of action is an absolute necessity here. He deplores also the increase in the number of cases seen by the doctor, from eight to ten per hour. The Shakespeare-street School for Stammerers dealt with 57 cases in six courses—48 boys and 9 girls. Analysing 100 children chosen haphazard out of those already treated at this centre, 78 per cent. might be regarded for practical purposes as normal speakers, 45 of these had perfect speech, the remaining 33 speaking perfectly normally to the ordinary listener, but stating that under stress of excitement or if in a state of poor health there is an occasional hesitation of varying degree—this, they say, they are able to control so that the interruption is scarcely perceptible to the listener; 17 stammered at intervals but not to such a degree as to unduly interfere with their occupation; five stammered in a pronounced fashion. The number of cases of scabies has decreased by 236—almost one-third of the decrease being attributed to the Norwegian treatment by Marcussen's ointment [3] which has been used at the special skin clinic here for two years. The treatment is now given in a special department of one of the clinics, and one nurse, one bath attendant, and one bath are now made use of instead of the two nurses, three bath attendants, and three baths of the previous year. The number of children examined was 35,574 in the routine group, 27,729 "specials," and 24,415 "re-examinations." The number of inspections made by nurses for uncleanliness was 235,359. Dr. Brown Ritchie urges the necessity for day open-air schools for the 2000 cases found specially suitable during the past year, and the insufficiency of accommodation for mentally defective children is also brought to the committee's notice; the accumulation of cases now waiting to be dealt with amounts to 900. In the medical officer's opinion, with such an accumulation and in the absence of provision for special training of children over 14 years of age, it is inexpedient to retain all cases until they have reached the age of 16. This is a point which decidedly requires consideration by the majority of education authorities at an early date. The coloured chart at the end showing the growth of medical inspection and treatment since 1915 is very striking and speaks for itself.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 10, 1923.

EDUCATION IN OTO-LARYNGOLOGY.

The Semon lecturer acted wisely in choosing as his subject a plea for adequate training of the student and graduate in laryngology and otology, and for closer coöperation in the conduct of clinics and in collective investigations in these subjects; and we believe that Dr. Logan Turner's address, delivered at the Royal Society of Medicine on Nov. 1st, will do much to further the cause which he has at heart, the advancement of oto-laryngology in this country. Two recent educational alterations have considerably affected the relations of the student to these subjects. In the first place, the new regulations of the General Medical Council have now made instruction in laryngology and otology compulsory for every candidate seeking a degree in medicine and surgery, and, secondly, the Conjoint Board have decided to grant, after examination, a special diploma in oto-laryngology, the object of which is, more particularly, to provide what may be called a hall-mark for medical officers working under the Ministry of Health and the educational authority, whose duties are largely concerned with disease of the throat and ear. Dr. Turner points with satisfaction to these two signs of progress and believes, we think rightly, that the public will benefit from the improved training which the medical officers will receive, and that the specialty will gain prestige through the better conduct of the work performed. He advises all who are interested in the welfare of these branches of medicine and surgery to consider carefully the best means to provide both the student and the budding specialist with adequate training, and, beside these two points, he considers that a third and most important matter is to afford improved opportunities for education to the teacher himself.

For the education of the student Dr. Turner suggests a ten weeks' course of mixed didactic and clinical instruction, consisting of three meetings per week for each student—that is, 20 hours devoted to clinical work and ten to lectures—and he gives his opinion that a considerable amount of useful knowledge can thus be imparted. As he says, it is all that can reasonably be granted to one of the subsidiary subjects; it is certainly an increasingly difficult problem for the student to find time to acquire even a minimum adequate knowledge of the continually expanding number of subjects which he has to learn. Some knowledge of diseases of the throat, nose, and ear is very necessary to the general practitioner, who finds that these diseases play a far larger part in his work than he had any idea of when he was a student. There is no doubt that a more intimate knowledge of the diseases of these regions, and of their relationship to disease of other parts of the body, than is at present usually possessed by the practitioner, would be of great value both to him and to his patients. The article by Dr. A. L. Yates on Painless Maxillary Sinusitis, published in our issue of last week, and that by Dr. T. B. Jobson on Unsuspected Nasal Sinus Disease in this number, are witnesses of how easily common intranasal diseases may be overlooked by those who have not been taught to expect them, and how various and far-reaching their reactions on distant parts of the body may be.

For the education of those intending to become specialists Dr. Turner recommends a very thorough course of training, occupying some five years after qualification, of which the first two years, we are glad to see, are to be spent in general training either at hospital or in private practice. He urges that the special hospitals, and special departments of general hospitals, should demand from candidates applying for appointments to the staff evidence that they had undergone an adequate training on the lines that he describes, and he believes that until this is an invariable rule we cannot hope to see a change in the mental outlook of the young specialist towards his training. While we agree that at present no such regular course is followed as that prescribed by Dr. Turner, nevertheless we think that aspirants for staff appointments to the special departments of our more important hospitals will be found to have worked and studied industriously for fully the period he suggests. Dr. Turner thinks that the Fellowship of a Royal College of Surgeons on its present basis should not be an essential qualification for appointment to the special departments of a hospital, and considers that this rule induces the prospective specialist to devote the greater part of his time and energy to general surgery; he suggests that the Royal Colleges should grant a Fellowship to the oto-laryngologist on a special basis, after a prescribed course of study, by examination confined to the anatomy, physiology, pathology, and surgery of the territory embraced by the two specialties. It is an interesting point, and Dr. Turner has rendered a service in ventilating it; we think that many will consider that to abolish the necessity for the ordinary Fellowship would be to destroy that sound groundwork of general surgery which is so essential to the specialist, and that it should not be replaced, though it might be supplemented, by a special examination.

On the education of the teacher, Dr. Turner makes a powerful plea for better organisation of the clinics and special departments, so as to make time and opportunity for teaching on a larger scale; in the clinic better team-work, closer coöperation between the various departments of the same hospital, and more coördination between special hospitals and departments throughout the country, and even throughout the Empire. He urges that, as a preliminary, all clinics should adopt one and the same system upon which to classify the diseases of the specialty, and, finally, he gives instances of subjects which offer a hopeful field for collective investigation. Dr. Logan Turner has performed a service, not only to his own specialty but perhaps also to others, for all would benefit by improved facilities for education, by better organisation, and by greater coöperation.

◆

THE MINISTER OF HEALTH'S OFFER.

After a real discussion with representatives of the panel executive the Minister of Health has made his final offer of terms for a new contract with insurance practitioners. This offer is in the form of a letter to the Insurance Acts Committee, which has been widely circulated, but which we print again for convenience on page 1047. The Minister was accompanied by his Scottish colleague, so that it may fairly be concluded that the terms apply to the whole of Great Britain. Whether this offer represents, as the Minister hopes, a reasonable and fair basis of settlement "under the present circumstances," can only be determined by those who know what are the present circumstances to which the Minister refers. It seems clear enough that stringent economy is a necessary item of Government policy. As part of the new offer the Government actuary is prepared to meet an actuary nominated by the doctors, and if it be clearly shown that there is no more money available, no doubt the insurance medical service will do well and wisely to accept the former of the Minister's alternative offers in paragraph (5). This alternative would fix the capitation fee at 8*s.* 6*d.* for a period of five years, unless the Royal Commission to be appointed should suggest material alteration in the conditions of service. Our Special Commissioner has formed the impression that "under the present circumstances" this offer will be regarded as acceptable by panel doctors in one area at least, although it would be premature to forecast a decision which will have to be taken by representatives of all the panel committees of Great Britain at the special conference to be held on Nov. 14th.

The final discussions with the Minister of Health appear to have been in the nature of real negotiation, and the conditions laid down in the earlier paragraphs of the Minister's letter make it far easier for the doctors to accept with good grace one of the alternative offers. A formula which is set out in paragraph (1) runs as follows:—

> "Medical benefit is, with sickness, disablement and maternity benefits, one of the primary benefits under the National Health Insurance Acts. Other benefits are additional and contingent upon the foregoing being first provided. The question, what is the proper amount of remuneration to be paid to the doctors, is one to be determined on its merits by the Government after due inquiry and after negotiation with the representatives of the profession."

This will go far to allay the uneasy feeling that approved societies have manœuvred themselves into a favourable position for taking over the control of medical benefit. The formula is something like a pledge, which we desired to have from the responsible Minister, that this fear was ill-founded. The economy campaign, it is now seen, created a real danger of separation of the insurance service from the rest of the health services of the Ministry. Self-supporting and self-contained, the service would be at the mercy of the men who are now telling the public that the Minister of Health's offer will deprive insured persons of their legal rights. For this reason we have set out alongside the offer, and at the risk of vain repetition, what it was that happened in 1911; for the same principle is now involved, and, if it is to be overthrown in 1923, the reversal of policy must be made by authority of Parliament after weighing all the relevant facts, and not by any form of administrative action.

The promise of a Royal Commission gains importance in view of the Premier's statement at Swansea on Oct. 30th, that instructions had been issued for a far-reaching inquiry into the manifold possibilities of social insurance. This declaration seems to foreshadow a wider scheme of protection for the worker against sickness, accident, unemployment, and poverty in old age. In spite of the prevailing industrial depression the existing unemployment insurance has recently been shown to be solvent. We may hope that the Royal Commission will see its way to review this wide field of social insurance in so comprehensive a manner as to include the reform of the Poor-law, and to secure its machinery of medical relief for the purposes of a complete health insurance scheme. The delay in the transfer of Poor-law medical institutions is hardly tolerable. Finally, the increased mileage grant to the rural practitioner will help to solve the knotty problem of working expenses in sparsely populated areas. The wonderful solidarity of panel doctors, with the support behind them of all other branches of the profession, has, we feel sure, been a potent factor in producing the greatly improved situation. The Insurance Acts Committee may be congratulated upon the loyal support which it has received, and on the large measure of approval shown in the public press of the country. As one of the most friendly of our daily contemporaries has put it, a settlement on the lines of the Minister's final offer would end the acute phase of the panel controversy and enable difficulties which have arisen to be examined quietly and efficiently. The precise fee which it is just and possible to pay to the panel doctor is only one of the difficulties to be considered.

◆

INSULIN HYPOGLYCÆMIA: DANGERS AND PRECAUTIONS.

THE advantages of insulin in the treatment of diabetes mellitus are now well recognised; the dangers, although they have been described, are not so well recognised, partly because the treatment has been confined to comparatively few patients who have been under fairly close supervision. The most striking effect of an injection of insulin is the reduction which takes place in the amount of sugar in the blood. It has been shown that when the blood-sugar of a rabbit falls below 0·05 per cent, the animal has a convulsion which may be of quite a short duration or which may kill the animal. This phenomenon has provided a useful basis for the standardisation of insulin. The quantity of insulin which will depress the blood-sugar of a rabbit weighing about 2 kilos below 0·05 per cent. in two hours is called three units. Tne exact cause of the convulsion is not known, but it is connected in some way with the amount of sugar in the blood since it can be checked in a few minutes by the subcutaneous injection of some grammes of dextrose. The rabbit then seems as well as ever, provided that the dose of insulin was not too big and enough sugar was given. Similar remedial effects can be produced by injecting either adrenalin, which raises the blood-sugar, or pituitary extract. In human beings the symptoms of overdosage are various. They do not, as a rule, occur unless the blood-sugar is less than 0·05 per cent., although they may occur when the blood-sugar is still as high as 0·09 per cent. The commonest symptom complained of is a feeling of inertia or lassitude, sometimes accompanied by slight dizziness, about three to four hours after the injection. This is often accompanied by sweating and abdominal pain, which is described as similar to a hunger pain. Tremor of the hands is often complained of and numbness of the hands, face, or tongue; diplopia may also be present. All these symptoms, although very unpleasant, do not put the patient in any danger of life. They may be relieved by giving, at once, a hot drink or some of the food which would have been eaten at the next meal. It is not necessary or desirable that patients should take sugar in order to relieve these symptoms. During the preliminary period of treatment in which the correct dose of insulin is being ascertained some slight symptoms are often unavoidable, but once the blood-sugar is normal and the size of the dose settled the patient should not experience any such symptoms.

The dangerous symptoms are: (1) a state of unconsciousness and (2) convulsions of a peculiar kind. The unconscious state is very alarming, and although it usually occurs after some of the milder symptoms already described it may take place in their absence. Unconsciousness may develop while the patient is talking or eating (just as a person may fall asleep while doing these things), and the state is very similar to one of deep slumber, from which, however, the patient cannot be roused, the breathing, pulse, and colour all being good. Although the rabbit has convulsions it was at one time thought that human beings did not suffer from them. The case described by Dr. C. M. HINDS HOWELL in THE LANCET of Nov. 3rd (p. 1007) is certain evidence of their occurrence. Moreover, in a pamphlet[1] which has just reached us through the Rockefeller Foundation convulsions find a place between aphasia and collapse in a list of symptoms likely to follow an uncorrected overdose. Although the condition is so easily relieved by the giving of sugar, it is one which calls for a widespread knowledge of the symptoms and treatment. It is certain that a patient who is taking more than 15 or 20 units of insulin and going about his occupation would be well advised to carry four or six lumps of sugar in his pocket, either dry or dissolved in water, in order to be ready for emergencies. This precaution will, by the way, add to the temptations of the dieted patient. It would also be well if the patient would carry a card about in a pocket or round his or her neck stating that he or she suffers from diabetes, is taking insulin, and has some sugar in a pocket. This precaution is suggested by the prospect of a doctor being called to see a patient who is either unconscious or having convulsions. If he did not know that the patient was taking insulin it is extremely unlikely that he would diagnose the cause of the condition correctly. A dose of sugar, either four or six lumps, dry or in solution, should be ample to restore the patient, provided that he can swallow. If not, a subcutaneous injection of adrenalin, 1 in 1000, minims 15, will restore the patient to consciousness within about five minutes. Sugar should be given afterwards in order to prevent any fear of relapse. If no adrenalin is at hand, pituitary extract, 1 c.cm., will also act very promptly. If neither of these is available, it will be necessary either to give the sugar by means of a stomach-tube or to inject about 20 g. of dextrose (5 per cent. solution) intravenously. In order to avoid the possibility of these dangerous symptoms arising the dose of insulin should always be moderate in size, and if larger doses than 20 units are being given the patient should certainly take the precautions described. The actual size of the dose which will be liable to cause dangerous symptoms will, of course, vary with the weight of the patient, the amount of sugar in the blood, and the amount of carbohydrate eaten after the insulin. When a patient has taken a large dose of insulin—say 30 units—and has eaten a definite amount of bread he does run a certain risk in that the bread may not be absorbed or, apparently after exercise, as in the patient whom Dr. HOWELL saw, may not be sufficient. One of the early causes of overdosage has fortunately been removed by the care with which insulin is now standardised under the auspices of the Medical Research Council.

It is not desired to deter any patient from having insulin, but rather to draw attention to the dangers in order that they may be avoided and that precautions should be taken in order to make the treatment a safe one. Forewarned is forearmed.

◆

A NEW THEORY OF THE ATOM.

THE termination of Sir HUMPHRY ROLLESTON'S tenure of office as President of the Rontgen Society during the twenty-fifth anniversary of its foundation was marked last Tuesday by the announcement of the incoming President, Sir OLIVER LODGE, of a new theory of the atom. He presented it as the sketch of an hypothesis to be criticised by physicists and assumed the nucleus (or proton) of the atom to be in rotation about its axis at a speed comparable with the velocity of light, thus giving it its large mass, some 1850 times that of the electron. He surmised that the normal ether contained its constitutional rotation, and that upon this, when a pair of electric units were being somehow generated, two equal and opposite rotations were superimposed, one opposing the original rotation and giving the net result zero and the other in the same direction giving a result slightly nearer to the velocity of light than before. Round the nucleus there might be an ethereal circulation essential to the existence and behaviour of the nucleus, very intense close to and decreasing with the distance according to the vortical or ethereal law, which would have, however, nothing to do with the laws of gravitation or electric force. It was possible to conceive of strata, where the speed would obey astronomical laws, or of gravitational or electrical levels. An electron would be carried forward by the fluid at that position that satisfied its own requirements. It would be attracted to the centre in a way that the fluid was not attracted, but would have sufficient tangential velocity to counterbalance the attraction. As by hypothesis the electron was only a modified part of the fluid, the revolution it would experience would not be one involving acceleration and consequent radiation, but it would abandon itself passively to the fluid. The levels would not occur at regular intervals, but in such orbits when the vortex velocity and the electronic velocity were of the same value. Intermediately there would be no equilibrium, and the electrons would fly out or in according to circumstances.

Sir OLIVER LODGE'S address dealt with the stages by which knowledge of atomic structure had been attained. After pointing out how and why X rays and their use in connexion with crystals had made an epoch in atomic research, he remarked on the fortunate chance whereby the silver salts on a photographic plate were sensitive to the rays. MOSELEY'S work, which showed how the elements were stepped up in simple arithmetic progression, had brought the theory of discontinuity right into the heart of the atom, and it was remarkable to note the way in which arithmetic conceptions were entering into physics when such natural units as atoms and electrons were employed. He protested, however, at the attempt to introduce the idea of discontinuity into space and time. The discovery of the quantum did not displace the laws of mechanics which still held. Discussing X rays from the medical standpoint, he noted that the radiation depended entirely on the nature of the luminous stimulus, and remarked how the recent progress of physics had made it possible for X ray workers to analyse the nature of the rays and make use of them for the purposes for which they were most suitable. He expressed a very marked preference for the kinetic atom of the physicists as contrasted with the static atom of the chemists.

◆

WE regret to announce the death of Dr. Thomas Henry Green, consulting physician to the Charing Cross and Brompton Hospitals, and author of the well-known manual of pathology, which occurred at his home in St. Albans on Monday last, Nov. 5th, in the eighty-second year of his age.

Annotations.

"Ne quid nimis."

THE LONDON FEVER HOSPITAL.

In years when the metropolis is free from serious epidemics the London Fever Hospital is apt to escape public notice. Like other hospitals under our voluntary system it has its common difficulties in the shape of high rates, increased prices, and the incidence of heavy taxation upon those classes which would normally furnish its supporters and its patients. In addition, it has its special difficulties in competing against rate-aided institutions. The Metropolitan Asylums Board can open, close, or change the character of its various establishments at discretion according to temporary requirements. The London Fever Hospital must continue to offer the specific facilities for which it was founded, and, unless adequate support is forthcoming in lean years, it must incur cumulative losses which in time may be fatal to its existence. Financial support, of course, is essential, but the need of money contributions is not so acute if the medical profession will give the equally valuable support of sending patients to be treated there. Not for one moment is there the slightest idea of underestimating the admirable treatment given in rate-supported institutions if we venture to suggest that there must be large classes of Londoners who do not wish for gratuitous treatment in Poor-law hospitals or at the expense of the rates. There must be many who at the same time are anxious to avoid the full cost as well as the risk and inconvenience of being treated for infectious illness in their own homes. And, though there are no class distinctions in medicine, there may be middle-class patients for whom the irksome period of convalescence will pass more cheerfully in a hospital where others of their kind are treated than in an institution open to all comers.

It has been suggested that the London Fever Hospital is not sufficiently well known to the practitioner. If this be so, it may be explained that this hospital was founded as long ago as 1802, being the first to be opened in London for the treatment of infectious fevers. It accepts for treatment and isolation patients suffering from all such fevers, including influenza, pneumonia, rheumatic fever, encephalitis lethargica, and cerebro-spinal fever, but not small-pox. It provides ward accommodation at 5*s.* to 7*s.* a day, as well as treatment in private rooms from 6 guineas a week, for scarlet fever, measles, German measles, and diphtheria cases, and the charges do not seem unreasonable. A doctor, it is true, though aware of the existence of these facilities, may yet feel a natural disinclination to lose sight of his patients by sending them off to Islington. He can, however, visit them there at any hour convenient to himself, though in practice it is probable that a single visit will be sufficient to reassure, since in addition to its resident medical officers the hospital has always been generously served by distinguished physicians from outside. Relatives, too, can visit patients in private rooms or wards, though for obvious reasons they are not advised to do so.

With the special facilities to subscribers—a form of insurance for householders—we are not now concerned. We are not addressing the subscribing public but the medical practitioner. If it be true that doctors are not fully aware of the existence and record of the London Fever Hospital, we commend to their notice an excellent institution which, if its beds stand empty much longer, is in serious peril of extinction.

THE BLOOD IN PSORIASIS.

Dr. Albert Strickler, professor of dermatology and syphilology, and Dr. Eugene Asnis,[1] professor of pathology and bacteriology of the Temple University Department of Medicine, Philadelphia, remark that although psoriasis is one of the commonest dermatoses, its specific cause and cure are still unknown. They point out that the bacterial theory of its origin to which they subscribe is supported not only by the clinical symptoms but also by the results of examination of the blood. A differential blood-count made by them in 27 patients suffering from psoriasis, which varied in type, severity, and extent, showed that 14, or 54 per cent., had a lymphocytosis of 35 per cent. or over, which was always at the expense of the polymorphonuclear leucocytes. The remaining white cells were all practically within the normal ratio. An examination of the blood smears was then made by Fontana's method to find some form of spirochæte, but with entirely negative results. Finally the Wassermann reaction was tested in 34 cases of psoriasis, two antigens being employed—viz., the alcoholic extract of human heart and the same antigen fortified by cholesterin. The anti-sheep hæmolytic system was used. The results were again negative in all cases. Commenting on their investigations the writers come to the conclusion that as marked lymphocytosis is often found in chronic infectious processes of both bacterial and parasitic origin, such as tuberculosis or trichophytosis, the presence of lymphocytosis in psoriasis is another sign-post pointing in the direction of bacterial origin for this common disease.

PROSTATIC DISEASE IN OLD MEN.

A paper by Dr. E. Platou in *Norsk Magazin for Laegevidenskaben* for October is an epitome of the advances made during the last ten years in the operative treatment of adenoma and carcinoma of the prostate. His material consists of 198 cases under the care of Prof. P. Bull between Jan. 1st, 1913, and Jan. 1st, 1923. There were 26 deaths and 117 cases in which a radical operation was performed, the 10 deaths among the patients operated on being equivalent to an operation mortality of 8·5 per cent. There were 152 cases of adenoma and 46 of carcinoma. It was somewhat remarkable that there was so little difference in the immediate mortality in these two classes; there were 19 deaths among the patients with adenoma, and seven among the patients with carcinoma, the mortalities being 12·4 and 15·2 per cent. respectively. These figures represent deaths in hospital, and when the late results of treatment are studied the chances of recovery are seen to be much greater for patients with adenoma than for those with carcinoma. Of the 152 patients with adenoma, 99, or 65·1 per cent., were discharged as cured, whereas only eight of the 46 carcinoma patients were discharged improved, three of them being found to be without signs of recurrence three years later. The ages of the patients in the two classes were practically the same, the average being 68·4 years for the patients with adenoma, and 69·7 years for the patients with carcinoma. But there was a marked difference in the average duration of the symptoms before the admission of the patients to hospital; it was four years and nine months for the patients with adenoma and only a year and a half for the patients with carcinoma. With regard to sepsis, it was observed that uneventful recovery often occurred in cases in which the urine was infected before the operation, whereas originally sterile cases sometimes showed severe post-operative sepsis. In more than half the number of cases (53·3 per cent.) the urine was infected before the operation, and Dr. Platou has come to the conclusion that the importance of an infected bladder before operation has been much overrated. In 40 cases the "rest" nitrogen in the serum was estimated, and in 28, or 70 per cent., it was found to be above normal. This test has proved an invaluable guide in deciding when to operate, and it is Prof. Bull's practice to wait till conservative measures have restored the "rest" nitrogen to normal before enucleating an adenoma. When the "rest" nitrogen content of the serum is very high he does not even attempt a cystostomy, but contents himself with passing a catheter twice a day, taking care not to evacuate the bladder completely till the functions of the kidneys have been at least partially restored. He has discontinued the use of a permanent catheter after operation, having found that, among 20 cases thus treated, there were as many as seven in which epididymitis, and three in which severe urethritis developed, whereas among 20 patients treated without a permanent catheter there was only one who developed epididymitis. The operation he prefers is the two-stage suprapubic operation under sacral anæsthesia with novocaine. Of 108 radical operations, 79 were performed in two stages and only 29 in one. The mortality rate of the two-stage operation was 7·6 per cent., and that of the one-stage operation 10·3 per cent. The fact that about 13 per cent. of all the cases of disease of the prostate in old men terminate fatally in hospital, whether the treatment be operative or conservative, clearly shows that, when urinary symptoms overtake elderly men, the expectation of life is appreciably shortened.

THE OCULO-CARDIAC REFLEX IN MUMPS.

IN a recent communication to the Medical Society of the Paris Hospitals, Dr. René Benard [1] refers to a paper by Margarot, who found the oculo-cardiac reflex present in 90 per cent. of his cases of mumps, though it was found in only 62 per cent. of normal subjects. This high figure is explained by Margarot having regarded as a positive reaction a diminution of only 6–8 beats a minute, which was present in two-thirds of his cases. Dr. Benard, on the other hand, who has examined the reflex in more than 50 cases of mumps, has come to the following conclusions. Mumps normally causes a pronounced bradycardia of the sinus type, but does not predispose as might be expected a priori to an increase of the oculo-cardiac reflex, which, on the contrary, is much rarer than in normal subjects of the same age. The conclusion may therefore be drawn that mumps reduces the susceptibility to this reflex. In cases where the oculo-cardiac reflex was obtained a much longer ocular compression was required than in the normal subject to produce it. Apparently, therefore, the permanent hypertonus of the vagus characteristic of mumps prevents any fresh stimulation. In 50 per cent. of Dr. Benard's cases the pulse did not vary in the course of the test. In only two did it fall below 50 after ocular compression; in 25 per cent. it was between 50 and 60, in one case between 60 and 70, in 12 per cent. it remained normal (between 70 and 80), and in 20 it exceeded 80.

EXPERIMENTAL HERMAPHRODITISM.

Dr. Wilhelm Krause,[2] of Reval, has succeeded in repeating Steinach's experiments on feminising male guinea-pigs by means of ovarian transplantation, although he has modified Steinach's technique by implanting the ovaries into the testicle instead of into the subcutaneous, intramuscular, or subperitoneal tissue. The main object of these investigations was to ascertain whether the action of the hormone derived from the implanted organ was dependent on the relative amount of ovarian and testicular tissue present, consequently he varied the proportion of ovary to testis as follows: Two ovaries were implanted into one testis, the other testis being removed; one ovary into each testis; one ovary into one testis, the other being left intact; half an ovary into one testis, leaving the other untouched, thus giving proportions of ovary to testis of 2 : 1, 1 : 1, ½ : 1, and ¼ : 1. Out of 44 experiments (of which 11 animals, unfortunately, died in the cold weather) 12 have, up to date, given positive results. Two to four months after the operation an unmistakable hypertrophy of the nipples became apparent, reaching, in one to seven months after the onset of growth, a maximum of 7 mm. in length, which is the normal length in a lactating female, whereas the normal length for a male does not exceed 1–1½ mm. The form of the mammary gland also took on the characteristics of a female, broad at the base, tapering cone-shaped to the apex. After a further three to four weeks the organ became smaller again but never regained its original size. Out of the positive cases, two belonged to the series in which the proportion of ovary to testis was ½ : 1. Sufficient time has not yet elapsed to show whether all the 33 animals will give positive results, but it can already be said that those with the low proportion of ovary are not behind the others in producing the characteristic changes. Thus the quantity of ovary does not appear to influence the effect of the hormone. At post-mortem examination the testicle operated on was found to be smaller than normal, but spermatozoa were present in the epididymis, and the seminal vesicles and prostate were normal. The contents of the seminal vesicles coagulated in the normal time, whereas it has been shown by Gley that in castrated animals the fluid loses its coagulability. Macroscopic examination of the testicle showed no normal ovarian tissue, although degenerated cystic tissue could be demonstrated. The results of microscopical examination are to be announced later.

THE CAUSES OF CHRONIC INVALIDISM.

SWEDEN is a country where every person, with an income below a certain limit, is entitled to a pension when ill-health or age inflicts permanent incapacity for work. In 1918 such pensions were given to 14,607 persons, of whom 5538 were men and as many as 9069 were women. A study of the morbid conditions qualifying these persons for pensions has recently been conducted[1] by Dr. G. Kahlmeter, consulting physician to the Government department which deals with these pensions. A medical certificate indicating the nature of the disability from which a prospective pensioner is suffering must show what the nature of this disability is, and it is interesting to note that in middle age women are much more subject to crippling by articular rheumatism than men. The fact that the ratio of women to men was as 1·6 to 1 was largely due to this factor; even when a correction was made to allow for the excess of the female over the male population the ratio of women to men was yet 1·5 to 1. This "super-invalidism" of women was not evenly distributed in the different age-groups. Beginning at the age of 40, it became still more evident during the following decade, reaching its maximum between the ages of 50 and 65. In this period the ratio of pensioned women to pensioned men was as great as 2 to 1. After the age of 65 the difference between the two sexes was much less marked, and it would seem that middle age is the period in which the wage-earning woman is most susceptible to the wear and tear of life. In 58·2 per cent. of the pensioners of both sexes the age of 65 had been passed, and only 15·2 per cent. were between the age of 60 and 65. Senile debility and arterio-sclerosis were the diseases qualifying for a pension in 55 per cent. of all the cases, and the disease coming next in the order of frequency was articular rheumatism, which existed in 9·1 per cent. of all the pensioners, 7·2 per cent. of the men and 10·2 per cent. of the women being given a pension on account of this disease. Pulmonary tuberculosis, on the other hand, qualified considerably more men than women for pensions, 7·9 per cent. of the pensions for men being on account of pulmonary tuberculosis, as compared with only 4·6 per cent. in the case of women. Among the pensioners under 45 pulmonary tuberculosis was the most common cause of invalidism, and in the younger age-groups epilepsy, valvular disease of the heart, and mental disease figured most prominently. The age of 40 to 45 was the age of predilection for articular rheumatism. It is curious to find such well-known diseases as ulcer and cancer of the stomach, asthma, chronic bronchitis, and organic disease of the nervous system playing such a comparatively modest part in these statistics, which constitute a useful supplement to mortality statistics.

THE ORIGIN OF HERNIA.

The Mitchell Banks Memorial Lecture was delivered, on Nov. 1st, in the University Surgical Theatre, Liverpool, by Sir Arthur Keith, who took as his title the Origin and Nature of Hernial Formations. After alluding to the frequency of hernia, he controverted the theory that all hernias were of developmental origin, and proceeded to show that, in the case of femoral hernia at least, there is no evidence of a truly congenital process of peritoneum ever being found, while the factors present are those associated with hernial formation due to pulsion from within. Chief amongst these are local weakness of the abdominal wall at a point where it is pierced by vessels, and the increase of intra-abdominal pressure caused by even the slightest muscular strain. Illuminating parallels were given in the herniæ of the mucosa at the orifice of the bile-duct near the duodeno-jejunal flexure and in the sigmoid colon. Passing next to the subject of inguinal hernia, the speaker described the descent of the testis as a process of growth, and in no sense a pulling down by muscular contraction. The lower portion of what has been known as the gubernaculum testis he prefers to call the "inguinal strand," as it never fully develops into muscle tissue. Sir Arthur Keith looks upon it as the representative of the suspensory muscle of the marsupials. The true gubernaculum follows the track formed by this inguinal strand, and as it goes replaces it by newly developed cells. The essential element in the prevention of inguinal hernia is the unimpaired action of what the lecturer would like to call the "inguinal shutter"—that is, the lower arched border of the internal oblique contracting, straightening, and so descending over the internal ring, like the upper eyelid over the eye. This action is an unconscious reflex preceding voluntary effort of any kind, and may be interfered with by any abnormal abdominal condition. Once a sac has formed, nothing short of its removal will allow the shutter to work, or, as Sir Arthur Keith graphically put it, "until you take your coat-tail out of the hinge you can't shut the door." Finally, in reference to the medico-legal aspect of hernia, the lecturer lent the weight of his authority to insist on the extreme rarity of any truly traumatic hernia—that is, of a hernia the result of actual tearing of tissues by a single sudden violence.

SYPHILITIC CHANCRE OF THE VAGINA.

Dr. Paul Lhuillier[1] devotes his Paris thesis to a consideration of syphilitic chancre of the vagina, the rarity of which he illustrates by the following statistics. Among 249 cases of syphilitic chancre in women Fournier noted only a single example of vaginal chancre, and even that was doubtful. In the late Prof. Gaucher's service at the St. Louis Hospital in Paris, out of 1182 patients observed in the course of ten years in whom the chancre was definitely localised, Bobrie de la Rochelle found only four instances of chancre of the vaginal wall. Dr. Lhuillier himself has collected 12 cases from the literature, in addition to two which are original. In only nine, however, was the localisation of the chancre exclusively vaginal, the others being examples of chancre of the vulvo-vaginal region. The comparative immunity of the vagina in this respect, which may be compared with the immunity of the face from chancroid, scabies, and psoriasis, of the œsophagus from diphtheria, and of the upper respiratory tract from thrush, has not hitherto received any satisfactory explanation. In the great majority of cases vaginal chancre is situated in the posterior third or anterior third of the canal, while it is very rarely found in the central portion. In shape it is usually round, but it may be oval or irregular in outline and vary in size from a few millimetres to a five franc piece. Contrary to the prevalent opinion, the induration is sometimes so ill-marked as to be hardly appreciable even by the most experienced examiner. It is usually of short duration, quite superficial, and rapidly disappears under treatment. Syphilitic chancre of the vagina is quite painless, and can be pressed with the speculum without causing any discomfort. According to Ricord, the characteristic adenopathy is found in the groin when the anterior third of the vagina is affected, and in the pelvic glands when the other two-thirds are involved, but subsequent observers have noted that the adenopathy is inconstant. Dr. Lhuillier recommends that in every doubtful case of vaginal ulceration a search should be made for Ducrey's bacillus and the *Treponema pallidum*, and that the Wassermann reaction should be performed every fortnight up to 50 days after appearance of the lesion. If the result is positive, active treatment by intravenous injections of arsenobenzol should be instituted.

THE MENTAL INEFFICIENT: "TREATMENT" OR "PUNISHMENT"?

The city of Birmingham has in some measure realised the vision of Dr. A. E. Naish, who, on the opening page of our present issue, forecasts the rôle of medicine in deciding many questions involving moral conduct. In the "Birmingham Scheme"—as it is now frequently called—the justiciary court refers for special medical examination a certain type of delinquent, who can neither be classified as mentally defective nor as insane, but in whom "mental instability is exhibited either by conduct, attitude, or bearing, or oft-repeated commission of the same class of offence or other abnormality"—persons, in short, who cannot adapt themselves to the requirements of civil life. The examination is carried out by two colleagues, Dr. Hamblin Smith, medical officer of the prison, at which special facilities are provided for the purpose, and Dr. W. A. Potts, psychological expert to the justices. The scope of their work has already been outlined by Dr. Potts in The Lancet,[1] and the methods employed in testing the mental capacity of cases referred to them were detailed recently in these columns.[2] The scheme was inaugurated just after the war and the results have proved the value of the experiment, about 150 cases being examined per annum. This number has remained fairly constant, as the justices recognise the difficulty of justifying any indiscriminate remanding of offenders, even if it were thought desirable.

In the report for the year 1922–23 by the two medical officers pointed attention is called to the fact that of the cases specially remanded it was found necessary to sentence only 20 per cent. to imprisonment. Dr. Hamblin Smith continues: "Even when every allowance has been made for the fact that some of the cases would not have been sent to prison in any event, the figures are more impressive than any words as to the immense social value of the scheme. The constant requests which I have had for information, not only from this country, but from all parts of the world, indicate the interest which is taken in our methods, and suggest that the scheme is, as it was intended by its originators to be, a real advance in legal procedure. But our natural satisfaction must not be allowed to cause any relaxation of our efforts, nor must we forget the work which still remains to be done. We must continue to examine as many cases as is possible. Only in this way can we have any prospect of obtaining the knowledge which is so urgently wanted as to the prevention and cure of that social disease which we call 'crime.' We can make no progress unless we study causations, and this study can only be pursued by the intensive investigation of individual offenders. In dealing with any case, a court is quite in the dark as regards the most important factors, until information is before it as to the mentality of the offender. This information can be obtained in no other way than by the use of medical examiners who possess the requisite experience. There is no type of case which is not worth investigation in this way. But I would call attention to two classes of offenders who are specially deserving of patient study. The desirability of the thorough examination of young offenders is now generally recognised, and there is also the offender who commits 'sexual' crimes, in whose case the mental conditions which may be found are varied in the extreme. I would urge that every case of this latter form of offence should be specially examined. I have been greatly impressed with the value of friendly interviews with the younger prisoners; most valuable information can be had in this way, not only as to the particular case, but also as to the causes of delinquency in general. It is to a doctor that the ordinary offender will talk most freely. This fact, for which there are many reasons, is constantly brought before me in my work.

---

[1] The Lancet, 1922, i., 1365.
[2] Ibid., July 21st, 1923. p. 112.

"Insane persons have long been regarded as requiring treatment instead of punishment. In comparatively recent years the mentally defective offender has been removed from the ordinary operation of the criminal law. But there are other classes of mentally abnormal persons which are quite well recognised by scientists, and which require treatment on special lines. Recognition of this fact in no way implies that these persons are to be allowed to do whatever they please, without interference on the part of society, any more than is now the case with insane or mentally defective persons. In their own interests, as well as in those of society, persons who suffer from these abnormal mental conditions require most careful treatment. The point is that our present method of dealing with them by imprisonment is inadequate, and, in many instances, futile. The whole problem of delinquency is a psychological one, and when once this is generally recognised I believe that public opinion will call for a revision of our present methods of dealing with offenders."

A little imagination shows the economy of dealing thoroughly the first time with a potential criminal, even if his study involves the examination of a number of cases who ultimately show nothing more than can be discovered by examination in court. "Psychological treatment" is not a synonym for leniency, as many laymen would believe. It represents rather the outcome of the desire to save lives which might be useful to the community, and as such it stands together with all other branches of prophylactic medicine.

THE REGISTRAR-GENERAL'S STATISTICAL REVIEW FOR 1922.[1]

THE issue of Part I. of the chief vital statistics of England and Wales for 1922 within ten months of the year to which they relate is a sign that the Registrar-General's statistical work is tending to function normally once more. Although we regret the failure of the text commenting on these tables to appear simultaneously, the present volume includes information of extreme value to physicians, and especially to medical officers of health. The average experience of the entire country is indicated by the fact that the birth-rate was 20·4 per 1000, a lower figure than in any preceding year except three of the war years; and by the death-rate of 12·8 per 1000, which, with the exception of 1921, is also the lowest on record. The rate of infant mortality was 77 per 1000 births, the lowest rate in any previous year having been 80 in 1920.

Perhaps a chief use of the tables in this report is for medical officers of health of counties and county boroughs in enabling them to compare the relative position of their areas in respect of the chief causes of death. A few extreme cases may be taken in illustration. Among county boroughs the death-rate per million from enteric fever varied from 41 in Blackpool, 52 in Dudley, and 40 in Plymouth to nil in 16 county boroughs, a difference which calls for much serious investigation in the boroughs named, and in others which approximate to their position. The death-rate from respiratory tuberculosis was 611 in Southport and 1250 in South Shields; 681 in Wolverhampton and 1364 in Warrington; 761 in Bolton and 1321 in Liverpool; 732 in Lincoln and 1321 in Manchester. These differences are most striking, and can scarcely be explained solely on an industrial or social basis. Similarly the death-rate per 1000 births from diarrhœa and enteritis under two years varied from 2·85 in Bath to 12·56 in Birkenhead; from 2·68 in Burton-on-Trent to 7·67 in Burnley; from 2·96 in Exeter to 11·06 in Gateshead; from 3·14 in Ipswich to 15·31 in Kingston-upon-Hull. These immense variations call not only for much heart-searching on the part of the local authorities concerned, but for active local investigation on scientific lines, with a view of ascertaining means for reducing the excessive death-rates towards the level of the rates in the more fortunate or better governed boroughs. Similar remarkable discrepancies are seen in the death-rate from puerperal sepsis (per 1000 births). This was 0·92 in Blackburn, but in Bolton was 2·05. In Bradford it was 3·26, in Bury 4·26, and in Chester 4·62, but in Coventry it was only 0·82, and in Darlington 0·66. Are these differences entirely accidental, or can they not be related to differences in the standard of the midwifery service available in the respective areas?

Similar questions suggest themselves when we turn from special diarrhœal mortality to total infant mortality under one year of age per 1000 births. Why should this be 62 in East Ham and 113 in Burnley; why 73 in Warrington, 76 in Huddersfield, and only 61 in Wallasey; why 113 in Walsall and in Wigan, and 70 in Swansea? Factors are complex and difficult of discrimination; but careful comparative inquiry can give indications adequate for reform; and there is no reasonable doubt that the high infant death-rates can be lowered approximately to the level of the lowest rates in the Registrar-General's tables. To point the need for inquiry and subsequent reform is among the chief ways in which our national vital statistics can be made of practical value.

SOCIETY OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE thirty-sixth annual meeting of the Fellows and Members will take place on Thursday next, Nov. 15th, at the Royal College of Surgeons of England, at 3 P.M. Dr. Sidney C. Lawrence, the hon. secretary of the Society, has circularised the Members and Fellows of the College resident in the greater London postal district area, urging their presence to support two resolutions to the following effect: First, that the admission of Members to direct representation on the Council of the College is desirable; and secondly, that the President should be requested to make a statement as to the difficulties, legal and otherwise, which prevent such direct representation of Members on the Council. The officers of the Society, in drawing attention to their objects, take the opportunity of protesting against the view that their action is due to a desire to obtain representation on the Council for their own supporters. The circular note indicates that other matters to be brought forward at the meeting will be the absence from official lists of the diploma titles, and the slur upon the status of the Members due to the absence of a hood from academic dress. It is felt that the right of the M.B. of any University to wear a hood upon public occasions creates a distinction which is not warranted. The general objects of the Society may be described by saying that it is desired to arouse and maintain amongst Members an interest in the College, and to obtain a new charter which will give them representation upon the governing body.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XLIV.

THE TREATMENT OF INTERNAL DERANGEMENT OF THE KNEE-JOINT.

INTERNAL derangement of the knee-joint in a large majority of cases means an injury and displacement of the internal semilunar cartilage. This accident may occur at all ages, though it is rare before adolescence; it is naturally more frequent in early adult life during the period of greatest activity. The initial injury is a twisting strain upon the flexed knee. In many cases this initial injury is a severe one, but in some a comparatively slight twist upon a flexed knee when the quadriceps is not on guard may be sufficient. The twisting strain first stretches, or even partially ruptures, the internal lateral ligament; this allows the inner condyle of the femur and the head of the tibia to separate a little, so that the cartilage can displace slightly towards the centre of the joint. It is now liable to be split by pressure between the two bones, and when a split has once taken place the fractured cartilage can then be displaced further. An actual displacement of the cartilage can only take place after a split or fracture has occurred. The most common variety of injury to the cartilage is a split round the margin, leaving that portion of the cartilage which forms a free edge in the joint loose and attached only at its anterior and posterior extremities. This variety of split is often called a "bucket-handle" injury. In some cases such an injury affects only the posterior part of the cartilage; in others it extends completely round the margin. Sometimes, either at the time of such an injury or at some subsequent period, this free portion of the cartilage is torn right across at its narrowest point, there being then one or two free tags of cartilage in the joint. The clinical characteristic of a displacement of the internal semilunar cartilage is that following a twisting strain the knee becomes fixed in a condition of partial flexion with external rotation of the tibia (so-called "locking"), and that this fixed position can only be overcome by a manipulation of the knee by the patient himself or by some assistant. Sometimes a temporary or partial locking of the knee occurs, easily reduced by the patient simply flexing and extending the knee-joint. An acute displacement is usually followed rapidly by effusion into the joint. An occasional incident is the occurrence of a chronic or recurrent enlargement of the bursa between the inner head of the gastrocnemius and the semimembranosus; this appears to be often directly associated with an injury of the posterior part of the cartilage.

Treatment of Acute Displacement of the Cartilage.

When the knee has become locked in a flexed position as the result of a characteristic twisting strain the immediate treatment must aim at a reduction of the cartilage back into its original position, or at least into a position in which it no longer interferes with the free mobility of the joint. In most cases this manipulation will be best carried out under an anæsthetic. The object of the manipulation is to open up the space between the femur and tibia anteriorly and on the inner side, and so to enable the cartilage to spring back into position. The surgeon flexes the knee fully, rotating the tibia outwards, gripping the ankle with one hand and the outer side of the thigh just above the knee with the other. From this position the knee is extended suddenly, the thigh being pressed inwards, the ankle being pulled outwards and kept rotated out; the cartilage will then be felt to return into its position with a snap. When the manipulation has succeeded, the next step is to prevent the formation of considerable effusion or to get rid of any effusion already present. This is best carried out by wrapping the whole of the knee from mid-calf to mid-thigh in a thick layer of cotton-wool and bandaging firmly over this with a domette bandage; the elastic pressure thus kept up will often completely prevent an effusion or promote the absorption of an effusion within 24 or 48 hours. There is no need at this stage to rest the knee—in fact, a considerable amount of exercise is useful, provided that no risk is taken of twisting the tibia on the femur. Steps should at once be taken to keep the quadriceps muscle active and prevent it wasting. Daily faradic stimulation to the main mass of the quadriceps and also to the vastus internus is advisable, together with massage of the knee itself and active exercises of the quadriceps. In carrying out these exercises two points are essential: (1) to restore complete flexion of the knee as tested by the ability of the patient to kneel and sit back on to his heels; and (2) to strengthen the vastus internus. The latter muscle has as its chief function to brace up the inner side of the knee and hold the patella inwards when the weight is being taken upon the flexed knee. The muscle should be specially exercised by making the patient tip-toe and then bend the knees until he is in a squatting position, recovering again to an upright position. As soon as any effusion has disappeared and the knee flexes fully, and the quadriceps muscle is as strong as on the other side, all sorts of general exercise may be taken. It is very common for an injury of the semilunar cartilage to occur with complete displacement and locking and for recovery to be complete without any subsequent similar accident happening. For this reason it is undesirable to operate upon a knee for the removal of a semilunar cartilage which has only been displaced once. When the knee has apparently recovered completely it should be used for every exercise that the patient desires to carry out, and tested in this way to see whether the cartilage is likely to displace again.

Recurrent Complete Displacement.

When displacement of the cartilage recurs in a knee which is apparently sound it is best to decide at once upon the removal of the cartilage. Such recurrent displacements tend to recur with less and less cause; the accident may happen in the course of ordinary walking, and may become a danger to the patient. Moreover, repeated attacks of displacement with locking undoubtedly damage the knee-joint, and sooner or later tend to produce osteo-arthritic changes. The operation for removal of a cartilage is usually carried out with a tourniquet applied to the limb. The knee is flexed at a right angle and allowed to hang over the end of the table, and a vertical incision is made on the inner side about three-quarters of an inch from the inner margin of the patella down to the head of the tibia. The capsule is divided vertically as far as the lowest fibres of the vastus internus and down to just beyond the margin of the tibia. When the joint is opened a hook should be passed under the cartilage, the synovial membrane retracted, and the anterior half of the cartilage then inspected. In most cases where the history is clear a fracture around the margin of this part of the cartilage will be found. The anterior extremity of the cartilage is first detached and a heavy clamp with a tooth at the end affixed to it. The margin of the cartilage on the inner side of the joint is then carefully cut away from the synovial membrane and capsule; the posterior part of the cartilage, if it is not detached may be left in the joint, the split portion being pulled forward and cut away from the sound cartilage posteriorly. In some cases no split is found in the anterior part of the cartilage. When the history is clear this portion must then be detached and pulled upon strongly, the knee being well flexed. The posterior part of the cartilage will then usually be ound to show a split which enables it to be pulled orward quite easily, so that it springs into the centre f the joint (the intercondylar notch); the split ortion can then be cut away posteriorly in this notch. n opening the knee-joint and removing the cartilage he most careful aseptic precautions must be taken, he skin being shut off from the wound, and nothing xcept the extremities of sterile instruments intro-uced into the joint. Care must be taken both in he original incision and in detaching the cartilage ot to divide the internal lateral ligament of the knee. The synovial membrane, capsule, and skin require uture in separate layers. As a rule the wound is utured and the dressing and bandage applied with rm pressure before removing the tourniquet. Pro-ided that healing is uncomplicated, and that no onsiderable effusion in the knee occurs, the joint may be moved and used quite soon after the operation. No splint is used; the wound is looked at on the sixth ay, and if there is no effusion in the knee-joint he patient is at once allowed to get up and walk on he limb. He is encouraged to carry out active movements of the quadriceps muscle; and electrical reatment of this muscle with massage of the knee nd active exercises can be started as soon as the titches have been removed. In a young adult it is ossible to allow a considerable amount of active xercise at the end of a month from the operation. uch forms of exercise as involve risk of twisting—.g., running, jumping, tennis, and football—should e forbidden until the quadriceps muscle has become uite strong; this may be a matter of two months.

Irreducible Displacement.

It occasionally happens that a cartilage has been njured and displaced and has not been immediately educed; it may then be a matter of difficulty to educe it. In any case in which manipulation under n anæsthetic has failed to secure full extension of he joint an operation should be undertaken forthwith, as a cartilage which remains in a displaced position is certain to produce damage to other joint tructures. In old-standing displacements it is as well for the surgeon to arrange to manipulate the nee under an anæsthetic, with permission from he patient to operate if the reduction is not felt to be satisfactory.

Partial Displacement of a Cartilage: Cases Simulating Displacement of a Cartilage.

Patients frequently complain of a knee which gives way under them constantly in a flexed position, often with pain and with occurrence of a subsequent effusion but without any complete locking of the oint. In some of these the knee is apparently normal between the attacks, and it may be taken hat there is probably a small split in the cartilage, he free portion of which is not large enough to get n the way and lock the joint completely. In many other cases an examination of the knee will show that lexion is not really full, and that the quadriceps muscle, particularly the vastus internus, is not as strong as it should be. In all these cases the best nitial treatment is to give an anæsthetic and manipu-ate the knee by flexing fully, rotating out, and then straightening the knee suddenly. Adhesions will often be heard to snap on full flexion of the joint. Following such a manipulation, the electrical treatment and exercises for strengthening the quadriceps already described should be given until the knee s fully mobile with good muscle power. General exercise should then be allowed, and the knee watched o see if any further accident occurs. If it does, an exploratory operation is indicated. In this class of case an X ray photograph to exclude the existence of a loose body is an essential preliminary of treatment.

THE PANEL CRISIS.

The Minister of Health's Final Offer.

The Minister of Health, accompanied by the Parliamentary Under-Secretary for Scotland, met representatives of the Insurance Acts Committee of the British Medical Association on Oct. 30th and 31st and discussed with them the terms of a new contract with insurance practitioners as from Jan. 1st, 1924. In the result the Minister made a communication as follows:—

Ministry of Health, Whitehall, S.W. 1,
October 31st, 1923.

Sir,—I am directed by the Minister of Health to refer to the discussions which have been proceeding between him, with the Parliamentary Under-Secretary of Health for Scotland, and representatives of the Insurance Acts Committee yesterday and to-day on the subject of the arrangements to be made for a new contract for the insurance medical service.

The Minister, appreciating the importance of an amicable settlement on this question, has given it the fullest possible consideration, and has made every effort in his power to realise the standpoint of the profession and to arrive in negotiation with their representatives at a settlement fair to all parties. In the result he authorises me to make the following proposals:—

(1) He accepts the following formula:—"Medical benefit is, with sickness, disablement and maternity benefits, one of the primary benefits under the National Health Insurance Acts. Other benefits are additional and contingent upon the foregoing beirg first provided. The question, what is the proper amount of remuneration to be paid to the doctors, is one to be determined on its merits by the Government after due inquiry and after negotiation with the representatives of the profession."

(2) An impartial Royal Commission will be appointed to investigate and report on the whole system established under the National Health Insurance Acts, including medical benefit and the remuneration of the practitioner. The terms of reference of this Commission will be agreed with the profession.

(3) Provided the Insurance Acts Committee nominate an actuary of suitable standing, the Government actuary is prepared to meet him in professional consultation with a view to satisfying him that all relevant considerations have been taken into account in arriving at his conclusion as to the maximum which can be charged to insurance funds as from Jan. 1st next.

(4) As regards England and Wales, during the next year a sum of £250,000 will be provided for the mileage fund and to meet other points raised with regard to the rural practitioner by the deputation which recently saw representatives of the Ministry of Health on the subject; the Scottish mileage to be discussed as heretofore with the Scottish Board of Health.

(5) As regards the arrangements for remuneration as from Jan. 1st next, the Minister authorises me to make the following alternative offers:—

(*a*) A capitation fee of 8*s.* 6*d.* to be paid for five years from Jan. 1st next, provided that, if the Royal Commission above referred to during the currency of that period suggests any material alteration of conditions of service, the profession shall be free to reopen the question of remuneration; or—

(*b*) A special court of inquiry will be set up by the Minister as soon as possible and instructed to report on the capitation fee to be paid as from Jan. 1st next. The contract will be made on the basis of the fee recommended by the court of inquiry, the Government undertaking to go to Parliament for the necessary legislative sanction and the profession undertaking to accept the recommendation. The court of inquiry will be asked to report as soon as possible, hearing any evidence tendered on behalf of the Ministry, the profession, the approved societies or other interested parties.

I am to say that the above offer is a final offer, and that it is to be taken as a whole with either alternative (*a*) or (*b*). The Minister hopes most earnestly that the offer may be accepted, and sincerely trusts that the Insurance Acts Committee and the whole body of insurance practitioners will realise that it represents a reasonable and fair basis of settlement under the present circumstances.

I am, Sir, your obedient Servant,
W. A. Robinson.

The Secretary, Insurance Acts Committee,
British Medical Association, 429, Strand, W.C.

The representatives of the Insurance Acts Committee stated that they would submit this communication to the panel committees of the country and afterwards to a special Panel Conference to be held on Nov. 14th.

THE ALLEGED APPROVED SOCIETY "CONTROL": WHAT HAPPENED IN 1911.

Not to prolong or exacerbate controversy but to ensure full realisation of a recurrent danger to peace, it is desirable, even at the risk of wearisome repetition, to bear in mind the early history of the relations between national insurance and the medical profession. From the very beginning it was foreseen that the profession would be prejudiced if the financing of the scheme were managed in such a manner that what was given to the doctors could be construed as something wrested from the approved societies. This was the point with which Parliament dealt fully and finally in 1911.

The best friends of the original National Insurance Bill of that year would hardly claim that either the Bill or the explanatory memorandum which accompanied it paid very marked attention to the medical profession's point of view. As Dr. Esmonde observed in Parliament at the time, the doctors were told to underwrite the health insurance of the country without being consulted as to the premium arrangements. There is no need now to assign praise or blame for what happened in 1911. The Bill was unsymmetrical in its conception. It was largely framed on a German design. But, whereas Germany had had a clean slate on which to plot out its scheme, England had already developed a characteristic voluntary system over a part of the area to be covered. It is the English way to adapt old material in making revolutionary changes, and the machinery of the friendly societies was obviously too useful to be scrapped. But the medical arrangements of the pre-1911 voluntary system—recently described by Sir Clifford Allbutt as "the bad and now obsolete club system, the old practice of pulse, tongue, and bottle"—had not been satisfactory to either side. They contained the element of friction which was the legacy bequeathed by voluntaryism to compulsion. The medical profession, as was clearly stated in Parliament by a responsible speaker (Sir Robert Finlay, afterwards Lord Chancellor), was not prepared to see the "control" which the friendly societies had exercised in the old days not only retained in their hands but even vastly extended. Yet, when the 1911 Bill came to be studied it was at once seen that the opportunity of friction was perpetuated. Clause 13 provided that medical benefit, in the case of members of an approved society, should be administered "by and through the society." It was repeatedly pointed out that the societies thus had a strong interest in cutting down medical remuneration in order to maintain or increase their own profits and to make their benefits more attractive. In replying on the second reading debate Mr. Lloyd George declared that all the criticisms of the Bill had been foreseen and that there was no substance in any of them. The doctors were not being "placed under the heel of the friendly societies" at all. Nevertheless the point was afterwards placed beyond doubt. Dr. Addison's amendment to take the medical benefit administration away from the societies and to hand it over to the local insurance committees (at that stage known as local health committees) found ready support on all sides. Some speakers emphasised the necessity of freeing medical remuneration from the grip of the societies, others the undesirability of entrusting the whole subject of health to private bodies unequipped for its adequate supervision. The Addison amendment was crucial; it was frequently stated that unless the point was conceded it was idle to proceed with the Bill. Mr. Lloyd George took the Government whips off, and the amendment was carried by the overwhelming majority of 387 votes to 14. Consequential amendments were made in Clause 14 of the Bill, and, as thus substantially altered, Clauses 13 and 14 eventually became Sections 14 and 15 of the 1911 Act.

This may be ancient history, but history has its lessons. The lesson of 1911 is that Parliament, on the advice of representative Members of all parties and by a huge majority, did what it could to ensure that, in working the new national insurance scheme, the medical profession was to be free from any suspicion of the societies' control. There was still, of course, a danger that the spokesmen of the societies, obsessed by the now discarded traditions of the old club system, would put their case too high, and, if thei funds were depleted by the grant of large additional benefits or (as in 1922) by external attack, would claim direct power to squeeze the insurance practitioner. This danger has proved only too real. A recent spokesman has described the apparent intentio of the Minister of Health to protect the reasonable remuneration of the doctors as a "misappropriation of trust funds." This impossible language merely shows the need of a clear statement that medical remuneration must be settled on its own merits irrespective of the societies' finances. Sir Alfred Mond, in a speech from which we quoted last week, assured the medical profession that the 1922 legislation made no modification of "existing statutory provisions." In other words, the protection given by Parliament on the Addison amendment in 1911 was not impaired by anything in the Act of 1922. W need scarcely add that there is no reason to suppos that Parliament is of a different opinion to-day. At any rate, if the principle of 1911 is to be overthrown it must be done by the authority of Parliament an not by any form of administrative action.

THE SITUATION IN EAST ANGLIA.

(FROM A SPECIAL COMMISSIONER.)

THE Eastern Counties took no small part in th early days of controversy over contract practic A week-end tour of Cromer, Norwich, Lowestoft, an Yarmouth, and conversations with many doctors, hav proved a liberal education. An armchair study o the problem, with only the written word as a guide is apt to conjure up a picture of the panel doctor a a unit, as impersonal in the discharge of his studie as a railway clerk or porter. It is only by travellin from place to place and listening to the experience of many doctors that a correct opinion can be formed not merely of the panel service, but of the men behin it. The very status of panel practice varies greatl in different parts. Lowestoft and Yarmouth, fo example, lie cheek by jowl geographically. Bu practically every doctor in Lowestoft is on the panel and about every other doctor in Yarmouth will hav none of it.

It is obvious that the standing of such a youn service as that of the panel must suffer when, in town like Yarmouth, many of the most respecte doctors will not work in it. However efficient th panel doctors may be in such a town, the demonstrative abstention of many of their colleagues put these panel doctors in an invidious position. I would have been unnecessary to labour this rathe painful point did it not have a certain bearing on th present crisis. If half the doctors in a town lik Yarmouth will not go on the panel when the conditions and rate of remuneration are as at present is it not probable that, if the panel service is to b modified in a manner distasteful to the medica profession, many of the doctors who now are a credi to it will give it up?

Take the case of the doctor with a large privat town practice, a hospital appointment, and speci knowledge of one branch of his profession. When all th men of this class in a town are on the panel, receivin perhaps only a few hundred pounds apiece from i the reputation of the service in such a town is eno mously enhanced, and its efficiency is increased i more ways than one. Now it is just this best typ panel doctor that the service has a precarious hold n. The young doctor who has recently bought a large nel practice is in a position to be sweated, and ere is no knowing to what level he could be reduced. ut the men of standing, experience, and ability are a position to say: "We will work in this service ly under conditions enabling us to give of our best. we are harassed by wrangling and shifting conditions service, we will return to a practice which is entirely on-panel."

This desire for a settlement of a more or less ermanent character is patent everywhere. Most anel doctors, if they must perforce decide one way the other, seem to prefer the Minister of Health's rst to his second alternative for the sake of peace, hatever their opinions as to the adequacy or adequacy of the terms. The gamble is greater in e second alternative. Most doctors, being very usy, have no taste for a gamble of this kind; they refer a gilt-edged security with a comparatively w rate of interest to speculative investments which eed watching and must be a constant source of istraction from their work.

"It is an ill wind . . . .," and it is to be hoped that this crisis gives birth to a Royal Commission with omprehensive terms of reference, many much eeded reforms will be adopted. The man in the treet, whose information is obtained only from the y press, is apt to conclude that reforms are, indeed, rgently needed, but that they must be solely of the ature of concessions from the medical profession. he size of panels must be reduced, freer choice of octors must be provided, better surgery accommoation must be found, and so on. But the aforesaid an in the street has no conception of the number of oints where the shoe pinches the doctor himself. any of these points are trivial, but their cumulative ffect is to be found in the 94 per cent. of resignations. ere is an instructive, perhaps typical case. A anel doctor takes a short but much needed holiday. e spends half of it in bed with the "flu." But those ays in bed are in some senses happier than the days pent at home in his panel with its endless routine f minutiæ. In addition to the dull, slogging, clerical ork there is the emergency night work—the sudden all coming on top of routine duties. May it not be ossible for a Royal Commission in consultation with the man on the spot" to simplify the clerical work f the panel doctor? A panel doctor your Comnissioner interviewed was convinced that the endless otes he has to make on unimportant cases are not nly useless but mischievous; they obscure the ecords of important cases, and it is impossible to see he wood for the trees.

To discuss in detail every grievance of the panel doctor would be impossible in this article. There re troubles in connexion with dispensing, and in seaside towns like Yarmouth and Lowestoft there is the difficulty of the insured visitor. Then there is the newcomer who may be in the district for years before he bethinks him of his card and brings it, or having meanwhile lost it, does not bring it, to a panel doctor who is at a loss to know whether he is treating an insured or uninsured patient. There is also the difficulty of the panel doctor who happens to have spent time and money on acquiring special skill in a particular branch of his profession. If the patient is to be free to change his doctor at shorter intervals than at present, this special knowledge may be tapped to the detriment of its possessor by the insured person going on the panel of an eye specialist one week and on the panel of a throat specialist the next. In a large town like Norwich, with more or less wholetime specialists not on the panel, and with few specialists on the panel, this point is of little significance; but it is not so in a small town like Lowestoft. A system of National Insurance which does not give adequate encouragement to panel doctors, as such, to specialise is surely imperfect. There is also the knotty problem of mileage, and a town like Cromer, with a large country district to serve, feels strongly on this point.

To return to the Minister of Health's alternatives, (*a*) and (*b*), your Commissioner did not hear one word in praise of the latter. The general attitude of panel doctors in East Anglia towards these alternatives might be summed up in the saying that: "The devil you know is better than the devil you don't know." This unknown, or at least uncertain, alternative would seem to have been put forward to add much needed charm to the first alternative by sheer force of contrast. The first alternative may not be palatable, but just look at the other! Taste it! Having done so, you find your palate so blunted that the unpleasant taste of the first alternative is hardly noticed. Emphatic endorsement was voiced with regard to the point raised in this connexion by Dr. Cox—that it is not usual to suggest that a party to a dispute should accept a reduction in remuneration pending the report of an inquiry.

It is not as premature as it may seem at first sight to touch on the future, five years hence. A doctor with a 2000 panel put the matter like this: "We have gone into the whole question carefully, and with our eyes open have deliberately sent in our resignations. We may, perhaps, on the advice of our leaders accept a reduction, and do our best to carry on for the next five years. But a further reduction at the end of this period will mean that breaking point has been reached."

It would not be fair to end these notes without a reference to the appreciative comments made as to the conduct of negotiations at headquarters. The representatives of the panel doctors enjoy the reasoned confidence of practically every doctor who touched on this subject with your Commissioner, and the leaders may be assured of appreciative loyalty from the rank and file in this area.

THE MOTOR EXHIBITION AT OLYMPIA.

(By Our Medical Motoring Correspondent.)

The outstanding feature of this year's exhibition at Olympia is the marked decrease in prices for all exhibits, coupled with increased value for money; prices, in fact, are almost on a lower level than before the war. The manufacturers have achieved this result through concentrating on the reduction of expenses, rather than on the production of a large number of different models. The present prices are based on an expected larger output. I believe many makers are adopting extreme measures to retain a footing in the trade and to meet foreign competition. At all events, the public is the gainer, so it is to be hoped that prospective car owners in return will encourage home industries by purchasing the products of British factories.

Six-brake Cars and Cushion Tyres.

Since putting forward my views last week[1] I have had the opportunity of examining most of the exhibits in detail, and my impression is that revolutionary innovations find no place in this year's display. In fact, as predicted, the only exceptional points are front wheel brakes and cushion low pressure tyres. The Rolls Royce Company are now fitting the former to their cars, and are doing so in addition to the ordinary four brakes. A specimen of the "six-brake" car is not shown, but all cars bought after a certain date will have the extra brakes fitted free of charge. The Talbot Darracq, Sunbeam, and Unic among others fit them now as a standard feature. The Talbot Darracq is exceptional in that it is almost the only car the price of which has not been reduced. It is now supplied with magneto ignition and priced at £495.

I have nothing to add to my remarks of last week regarding front wheel brakes and the new tyres; a further view has confirmed my list of cars that should be inspected. In addition to those previously named, the Hillman at £350, the 9 h.p. Hampton at £275, the new Unic, with a specially designed " body " for the doctor, and sold by Messrs. Mann and Overton of 10, Lower Grosvenor-place, should be considered. Among the lighter models the Bayliss Thomas Coupé, listed at 300 guineas, is worthy of note. Of the cars enumerated last week, the 12 h.p. Austin has been reduced in price to £375, and the 11 h.p. Standard now costs £230. The 12 h.p. Sunbeam is turned out for the reduced sum of £570, and is excellent value for this money. In fact, at the above figures, all the cars mentioned are, in their respective spheres, tempting investments. I might even go further and suggest that whichever make is chosen the purchaser will not meet with disappointment, if he takes due care of his property.

---

[1] The Lancet, Nov. 3rd, p. 998.

Catering for the Owner-driver.

In considering the care of the car I might mention that those who are not keen on undertaking a periodical overhaul themselves could with advantage consult the Light Car Maintenance Co., of 3A, Elm-road, Camden Town, who specialise in that class of work. A good many manufacturers provide a similar service, either at their own factory or through their agents. Those considering the purchase of a car out of income may be interested in some of the schemes proposed by Messrs. Offord, the coachbuilders, of Gloucester-road, Kensington. This firm also specialises in body work for the profession. Intending purchasers are certainly faced with an excellent choice of coachwork. The cult of the all-weather car has many followers, and the latest models include the added comfort of side curtains which open with the doors, and are not merely buttoned on. Adjustable front seats and pedals are another improvement bound to be appreciated by those who sit at the steering-wheel. Messrs. Barker and Co., Windover, Ltd., and Hooper and Co., among others, show carriage work which in design and colour is a delight. Those favouring the saloon body may be interested in the specimens shown on the Humber stand.

Many visitors were attracted to the galleries, and especially to the section given over to the tyre manufacturers. Messrs. Dunlop and Michelin both have produced tyres of larger cross-section, which thus holding an increased volume of air at a correspondingly reduced pressure, give a marked increase in cushioning capacity. They are not easy to fit on old cars, as they usually (on account of size) need additional clearances. Where desired, this is being arranged for on new cars. Messrs. Michelin fit these tyres on the ordinary beaded rim; Messrs. Dunlop use inextensible wired edges, and a special type of rim to retain the tyre in position.

Tyre Trouble Eliminated.

Among puncture proof devices, the Adey seems likely to give satisfaction. It is an inner tube, much thicker than the ordinary type, and it has in addition a light internal coating of a special rubber compound, which seals any puncture. Another solution is offered by the Jeff tube, the inside of which contains many rubber flaps; if a nail pierces the tube it pushes one of the flaps aside. When the nail is withdrawn, the pressure of air forces the flap back into position, and so closes any hole. At Messrs. Harvey Frost's stand many vulcanisers were on view. They certainly help to preserve the life of a tyre, especially the covers. A cut filled in and vulcanised may extend the existence of that cover for many months; ordinary stopping may, of course, stay in, but as a rule it does not. A properly vulcanised repair is much better. Until the advent of the self-starter we were all slaves to the crank handle, now such labour is of the past, but tyre inflation requires almost as much energy. This can be avoided by an engine-operated pump inflator, which is connected up to the engine, taking the place of one of the sparking plugs. The engine is run, and in about four minutes the tyre is fully inflated, an indicator showing when the correct pressure is reached. Another boon is the spare wheel, or, what is even better, the Warland dual rim. The undoing of a few nuts permits the flange to be lifted off, and a rim carrying an inflated tyre to be substituted. A simple ratchet is employed to expand the rim, and thus allow a gap piece to fall out, and the tyre is then easily removed.

Comfort and Efficiency.

Further exploration of the galleries revealed many other interesting novelties both for luxury and utility. I have at times had artillery wheels which became loose, so if possible I usually now advise Sankey wheels, which for tightness and power of resistance are eminently satisfactory. At the Zenith stand there were sectional examples of the working and adjustment of what is undoubtedly an ideal gas producer. In some cases, where two or more people drive the same car, it is often found that the controls are out of reach for one of them, and cushions must be used to obtain a comfortable position. To obviate this, Messrs. Mann Egerton have introduced a pedal extension, which can be put on or detached in a moment. They also show an ingenious car heater, in which the temperature is obtained by filtered warm air pre-heated by radiation. The danger of dazzling headlights has produced an enormous number of anti-glare devices. The best solution offered seems to be a contrivance, manufactured by Messrs. Brown Bros., Ltd., which causes the headlights to dip at the driver's will. Windshield cleaners are also shown in numerous patterns. I believe mechanical cleaners are better than the preparations for treating the screen, in overcoming the nuisance of fogged glass. Some of the contrivances are worked off the engine, others by electricity. A most efficacious one is the Dekla, operated by hand only. This firm has also a girderscope driving mirror which can be easily clipped to the pillar of the windscreen, and gives a very wide rear view. Among rear screens the Auster and Beatonson provides full protection and comfortable travel under all weather conditions. Many firms specialised in lubrication and were keen to discuss both that subject and their oils. There can be no question, if one wishes to obtain not only the greatest efficiency from an engine, but also the maximum life from the working parts with a reduction in wear and tear, lubrication of the working parts is the most important consideration. Well-known brands of oils, such as the Shell-Mex, the Vacuum Oil Co., and the Newton Motor Oil can be relied on. Cheaper oils sold in bulk may prove much dearer in the long run. It is a true saying that a motor engine may pay more in friction tax than in any other direction.

Insurance against Loss and Damage.

The prudent motorist is, of course, well advised to see that he is fully insured against all risks and at the White Cross, Car and General, Premier Motor Policies all information on this important subject could be obtained. Insurance to secure payment for hire of a vehicle during repair o insured one, as well as against theft of professional apparatus left in the car, seems worthy of consideration; also the previous fixing of replacement value of car in the case of complete destruction or loss.

Now that the winter is approaching the radiator muff shown by Messrs. Brown Bros. supplies a useful want, as does also an arrangement to maintain the temperature of the garage and thus avoid running the water off every cold evening. A Norton motor stove or a safety-lamp answers admirably. The Lodge priming plug, which permits of the easy introduction of petrol or ether into the engine greatly facilitates starting in cold weather. Among other good plugs shown are the K. L. G., Hobson, and Champion. Foot-warmers, an instarter device, various jacks, Parsons's non-skid chains, tyre-pressure gauges, automatic traffic warners, as well as clocks, watches, mascots, horns, car locks, &c., offered strong temptations to the buyer of moderate means.

THE WORK OF THE LEAGUE OF REMEMBRANCE (1914–1919).

HOSPITAL SUPPLIES ON A VOLUNTARY BASIS.

THE anniversary of Armistice Day is an appropriate ime for calling attention to the activities of the eague of Remembrance. The work of the voluntary ssociations in providing for the needs of the sick and ounded during the war has been freely recognised ; is not so generally known that such work is till being carried on in aid of civilian hospitals, elfare centres, and similar organisations, by the eague of Remembrance at 1, Marlborough Gate, ondon, W. 2.

The League, which is the direct descendant of the avendish-square depôt and the Mulberry-walk urgical Requisites Association, was founded to be a ving memorial to those who fell in the war, and to erpetuate the spirit of service which united the ation during the time of supreme trial. During the ar the sense of obligation to the community grew nd was organised, and a great deal of fluid energy nd goodwill received the training and discipline ecessary to harness it to the public weal.

Before the close of hostilities it had become vident to far-sighted observers that, if a means could e found to employ in the service of peace the energies o freely offered in war, it would be to the permanent ood of the community. A movement was inaugurated at Cavendish-square, largely at the instigation f the late Duchess of Albany, to carry on the work of ospital supply. A scheme was prepared under the ractical direction of Mrs. E. H. Gibson, C.B.E., the ead of the Cavendish-square depôt, and sanction as obtained from the Charity Commissioners to apply he funds in hand to the initial outlay. The scheme as further laid before the heads of the Mulberry-alk Association and, animated by a like desire to nd some means of establishing a memorial of perpetual ervice, they added their surplus funds to the capital vailable for establishing the League. A house was aken, suitably equipped, and opened by Princess eatrice, President of the League, on June 28th, 1920, nd under her patronage and guidance the work f making hospital equipment has gone steadily orward.

Requests from hospitals, welfare centres, and ublic nurseries, totalling 571, have been answered, vith the result that some 11,500 garments, from hrouds to surgeons' coats and baby clothes, have been nade. Over 370,000 surgical dressings have been repared, and, as the facilities offered and as the work lone becomes better known, the demand constantly ncreases. The procedure is simple. A hospital ends to the League headquarters such materials s it wishes to have made up, with a pattern ; the eague undertakes to do the work, and to deliver it vithin two months entirely free of charge. Incidentlly, the pattern is the hospital's affair ; the League akes no responsibility for that. As to the quality of he work the League has a high standard of excellence hat is rigorously maintained. At the head of each vorkroom is a salaried "sister" (always the widow r dependent of an officer fallen in the war) who is esponsible for the work done, and who must inspect nd pass every garment made in her room by the oluntary workers before it is sent out.

The supply of surgical dressings, in which the eague takes particular pride, has a definite reaction pon nursing, in that in many cases it relieves nurses rom the somewhat arduous task of "replenishing tock" at the end of the day. As long as it does not nterfere with the curriculum of training, the assistnce that the League gives to the nursing profession s most valuable. To cope with the ever-increasing olume of work the League requires a great many oluntary workers, and in consequence, the importance f social hygiene, the needs of hospitals, and the vork of welfare centres is constantly brought to the otice of a large number of women, who thereupon become propagandists and missionaries in the cause of public health. In this connexion a library has been founded and is shortly to be enlarged, in which official publications, such as reports of the Ministry of Health and authoritative bodies dealing with nursing, child welfare, preventive hygiene, &c., will be available, and may be expected to prove of great educational value.

The League workers, moreover, accustomed to the prompt and careful execution of orders, form a body whose services in the event of emergency, such as an epidemic, would be immediately available. During the recent small-pox outbreak application was made to the League for vaccination pads, which were at once supplied. In a graver emergency a like promptitude would be of the utmost service. In order that the work of the League may be kept on sound and up-to-date lines an advisory committee of medical men periodically review and criticise the progress of the work.

The personnel of this medical advisory board includes: Sir Frank Colyer, Sir Alfred Fripp, Sir Robert Hill, Sir Robert Jones, Sir Alfred Keogh, Sir William Arbuthnot Lane, Mr. John Murray, Mr. Leslie Paton, Sir James Purves-Stewart, Sir Alfred J. Rice-Oxley, Sir Hugh Rigby, Mr. C. Knox Shaw, Mr. H. J. F. Simson, Sir Joseph Skevington, Sir Arthur Sloggett, Mr. Herbert Smale, Mr. R. C. Jocelyn Swan, Dr. H. Campbell Thomson, Dr. Kate Marion Vaughan.

The Committee of the League welcomes suggestions that may increase its usefulness. It has on occasions placed its rooms at the disposal of organisations wishing to hold meetings on subjects connected with the national health and well-being. The present premises barely suffice for the work undertaken, and a scheme is in preparation for the endowment of a permanent establishment devoted to the making of hospital requisites on a still larger scale. It is proposed to raise a sum of £30,000 for the endowment and permanent establishment of the League, and for this purpose donations are invited.

A NEW X RAY DEPARTMENT AT WEYMOUTH HOSPITAL.

ON Nov. 3rd, at Weymouth, a new and well-equipped building, erected to the memory of the late Dr. James Miller, for many years on the staff of the hospital, was opened by Sir Humphry Rolleston, supported by Dr. A. E. Barclay, of Manchester. Mr. Clark, chairman of the hospital, presided at the opening ceremony, and referred briefly to the recent improvements which had been carried out in the hospital building. The new wing was then formally opened by Sir Humphry Rolleston, the text of whose speech is given on p. 1065 of this issue of THE LANCET.

Dr. Rodier Heath, the medical officer in charge of the X ray department, briefly outlined the progress of X ray work in the town, and said that when he first came there there was only a small 10-inch coil and an old dipper interrupter, but the work had grown, and it was found that a larger and more modern installation had become a necessity if this important and ever-growing branch of medicine was to be carried out in a proper manner. Unfortunately the present-day financial straits had made it very difficult to secure the necessary funds, but through the generosity of the late Dr. Miller's mother, and to friends, together with some £3200 raised by fêtes ably organised by Mrs. Sanderson-Wells, it had been found possible to build and equip the department, which he had no hesitation in saying was such as would enable him to carry out all kinds of X ray work thoroughly and efficiently. Dr. Heath then thanked Sir Humphry Rolleston and Dr. Barclay for the stimulus they had given to the work of the department. To Dr. Barclay, in particular, he owed a debt of gratitude. For many years Dr. Barclay had shown him great kindness in allowing him to study the methods of the X ray department at the Royal Infirmary, Manchester.

Dr. Barclay, in reply, congratulated Dr. Heath on the new installation. He then gave a brief outline of progress as exemplified by his own department at the Royal Infirmary, Manchester, where he had been working since 1908, at which time he only had one small room and a dark room in which all the work was carried out. Development had gradually taken place, and the work had increased by rapid strides, until the department had become what it was now with its many sections and nine sets of apparatus, including two for intensive treatment. He went on to say that he was convinced that great progress had already been made with this treatment, and that it was not too much to hope that by its means many forms of cancer could be cured, and also light thrown on the causation of this disease. He quoted one case in particular of which he had skiagrams showing a pelvis, riddled with sarcoma, and the condition now showed that the diseased bones had been entirely replaced by healthy tissue, and instanced many other cases where irradiation was of proved value. Work of this kind required a very high degree of skill, and should only be in the hands of experts.

In seconding a vote of thanks to the speakers, Dr. James Macpherson Lawrie referred in touching terms to his late colleague, Dr. Miller.

The department includes a large radiographic and screening room, which is lighted by three large windows fitted with wooden roller blinds, a treatment room for therapeutic work, and the usual dark rooms and office. The apparatus consists of a large oil-immersed "Snook" transformer, fitted with auto-control and time switches, which gives an output of 80 milliampères, a rotary converter for heating the Coolidge filament, and a 16-inch coil for therapeutic work. These were supplied by Messrs. Newton and Wright. There is also a screening stand couch, and a special table fitted with a Potter-Bucky diaphragm, and various tube stands and accessories, all of which were supplied by the Cox-Cavendish Electrical Co. The erection of the apparatus and designs were carried out by Mr. T. H. Escott, of Weymouth.

MEDICINE AND THE LAW.

Unjust Censure.

Several remarkable statements appear in the report of an inquest on the body of a married woman, 35 years of age, who apparently threw herself and her 18-months-old child into the Thames on some date between Oct. 13th, when she disappeared with the child, and Oct. 22nd, when her body was recovered. The dates are important, for it emerged from the evidence that the depression which culminated in suicide dated from a visit to the Battersea General Hospital, where she was told, after an X-ray examination, that she was suffering from tuberculosis of the spine. The date of this examination is not stated, but it must have been prior to Sept. 4th, when the patient attended the Brompton Hospital for confirmation of the report. This confirmation was not forthcoming, for, after further X ray photographs had been taken, the radiologist at this hospital stated that there was no disease in the cervical spine, and this information naturally relieved the patient's mind. Though it was more than five weeks after this second consultation that the woman disappeared, the coroner and the jury took the view that the previous diagnosis was the indirect cause of the suicide, and censured the hospital accordingly for "great indiscretion." Had the original diagnosis of caries of the fifth and sixth cervical vertebræ been established post mortem, which it was not, we presume that no censure would have followed. So long as diagnosis is an incomplete science, often upset by post-mortem evidence, it seems hardly fair to blame a hospital for an error of diagnosis per se. As to the alleged indiscretion, if the hospital authorities had good reason to suppose that the patient was afflicted with cervical caries, surely it would be in her interest to inform her of the fact in order that she might seek appropriate treatment. This brings us to the extraordinary pessimism of the coroner on this point. He is reported to have said "that for a person to be told that she was suffering from tuberculosis of the spine was almost like pronouncing sentence of death." Surely the prognosis of a young adult who undergoes treatment in a modern institution such as the M.A.B. hospital for cases of non-pulmonary tuberculosis for adults at Lowestoft (St. Luke's) is not so bad as this would suggest. This hospital having only been opened in May, 1922, end-results may not be available, but Rollier states definitely of the Leysin clinics that the prognosis of surgical tuberculosis is not less favourable in adults than in children, and F. Langenskiöld has recently reported from Helsingfors good results in 70 per cent. of his cases of cervical spondylitis. The coroner and his jury seem to have been unduly impressed with one side of the tragedy and not to have taken other possibilities into account. For example, it was presumably pain on account of which the patient originally went to hospital, and if this pain, as it turned out, was not of organic origin nothing is more likely than that the patient was of unstable mentality. The difficulties of medical treatment are likely to increase if an opinion based on careful investigation and X ray photograph is liable to be held responsible for an impulsive action committed weeks after the patient's mind had been set at rest by a subsequent reassurance.

Poor Persons, the Law, and Medicine.

The President of the Divorce Court recently called attention to the fact that a well-known K.C. and an equally well-known member of the junior bar were appearing before him without fees on behalf of a petitioner who was a charwoman, and who was assisted by a firm of solicitors who equally acted for her as for a "poor litigant." "These facts deserve to be known," said Sir Henry Duke. "The subject has been publicly discussed lately, and there is at the present time much doubt whether the existing arrangements for facilitating the settlement of matters of this kind for poor persons could be carried on." The medical profession, to whom gratuitous assistance for the poor is no new thing, are of course aware that a movement for giving legal help to the poor in the civil (not in the criminal) courts was started by the legal profession some years ago. It has never, however, as far as we are aware, become in any way general, so far as lawyers are concerned. In the medical profession men of the greatest eminence, as well as those in the ranks of general practice, are constantly aiding their humble neighbours, and are sometimes held up to obloquy for endeavouring to obtain even a modified fee for so doing. A medical witness who refuses to give evidence on behalf of a patient until he is paid for doing so is denounced as greedy, when the lawyers on the same side are not treating the patient as a "poor litigant," but are paid for their work. If barristers and solicitors wish to institute a system through which the poor may profit by their services, they should organise it on a wide basis. The fact that two eminent barristers have appeared together in a case, in which, probably, far less distinguished counsel would have produced the same result, is but a small step in that direction.

Tests of Intoxication.

At the Central Criminal Court a man named Wilmer 35 years of age, was tried upon an indictment charging him with causing bodily harm to two women when in charge of a motor-car by "wanton driving or other wilful misconduct," and was acquitted. The accident had occurred in a crowded part of the city in the afternoon, and the defendant, after being taken to a police station, was medically examined by Dr. R. T. Edwards who deposed that his face was flushed, his speech was ightly slurred, the pupils of his eyes were dilated, nd that his breath smelt very strongly of beer; he ould walk about the room, but when "toeing the line" aggered for the first yard. The Romberg test was pplied, and the defendant swayed more than would e expected in a sober man. Dr. Edwards, in cross-xamination, declined to admit that the symptoms hown were those of a man suffering from shell shock nd neurasthenia.

Sir W. H. Willcox, called for the defence, had xamined the defendant in consultation with his usual edical adviser, and had come to the conclusion that e suffered from shell shock and neurasthenia. He dded, in reply to questions, that he did not regard any of the tests applied at the police station as sts for drunkenness. They were tests for nervous isease. The dilatation of the pupils, he said, was only nportant in extreme cases of alcoholism. It was a ommon mistake at hospitals to regard the smell of lcohol as proof of drunkenness. The "toeing of the ne" test appeared to have resulted in the defendant's avour, and the Romberg test he regarded as for ocomotor ataxia and of no value in cases of alleged runkenness. It may be added that the defendant eclared in the witness-box that he had asked at the olice station for another medical man to be sent for nd that this had not been done, that he had claimed here to be sober and protested against his treatment, nd that he had only drunk that day a pint of raught beer in the course of a bread-and-cheese ncheon. He had, however, had very little experience f driving a motor-car. He had been out two or three imes with an instructor and had apparently held a icence for driving a motor-cycle in 1909.

In comment it may be observed that the tests pplied for drunkenness at police stations are very requently attacked in police courts in doubtful cases, nd that, if possible, tests should be devised of generally dmitted value and not likely to be questioned and iscredited. It need hardly be added that apart from ny question of shell shock or neurasthenia, the more rowded parts of London are not suited for drivers hose experience is limited to three or four trips with n instructor. Mr. Wilmer was, no doubt, perfectly ober but, apart from his case, it is to be remembered y all drivers that an amount of alcohol less than hat which would cause "drunkenness" in the popular ense may impair any man's judgment in a moment f emergency in a crowded street, and contribute to a erious accident.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh: The Care of the Convalescent, a New Departure.

THE opening of the first unit of the new Astley-Ainslie Institution on Oct. 20th by Lady Susan ilmour marks a new departure in the conception of onvalescence. Mr. David Ainslie, of Costerton, Midlothian, who died in 1900, left the residue of his very considerable estate for the purpose of founding an institution to be known as the Astley-Ainslie Institution, for the benefit of convalescent patients from the Royal Infirmary of Edinburgh. He directed that the funds should accumulate for 15 years for this purpose. The specified time elapsed in 1916, but, owing to war conditions, nothing in the nature of building could be done at that time, and the funds have been allowed still further to accumulate, so that the governors of the institution have now at their disposal about £600,000. Four houses have been acquired in the Grange Loan district with some 25 acres of ground, and these, when fitted out, will provide some 150–200 beds. The present unit has 34 beds. There is a resident medical officer and a trained staff. This institution is the first of its kind in this country or even in America. The existing convalescent home at Corstorphine is intended only for walking cases—for those, as it were, well on the road to complete recovery. Hitherto medical men have confined their attention chiefly to disease in its more or less acute stages and to a lesser extent to its prevention, whilst the gradual return to complete and normal health has been allowed to take place with little or no medical supervision. In a circular sent round to all the wards in the Royal Infirmary the aim and intention of the governors is stated thus:—

> The governors have decided to receive patients whose period of convalescence is likely to be prolonged, and/or who require continued institutional treatment and supervision, whereby recovery will be definitely hastened. . . . The governors are desirous that the opportunities afforded by the institution for the scientific study of the process of convalescence from different diseases should be systematically utilised, and they would welcome the coöperation of the members of the staff of the Royal Infirmary in suggesting and directing lines of investigation towards this end. It is hoped that the scientific study of the processes underlying recovery of health after illness may lead to improvement in the methods employed in the treatment of the convalescent stage.

Briefly, then, the importance is recognised of more adequate medical attention in convalescence and more scientific study of its processes. To the attainment of this desirable end the Astley-Ainslie Institution is dedicated, and Edinburgh is proud to be the first adventurer in this important field of medical work and knowledge. None can fail to see the great possibilities of the scheme for the improvement of the nation's health and efficiency. The more rapid recovery from disease and disablement, involving a smaller loss of working capacity, is of immense economic importance to the country, as is also the more complete recovery which should prevent much further disease and debility. More accurate and thorough study of convalescence may be expected to lead to advances in these directions and at the same time, not improbably, to considerable increase in our knowledge of the ætiology of many diseases.

University of Edinburgh: Election of Assessors to the Court.

Sir Norman Walker was elected on Oct. 25th to the University Court in place of Sir George Berry, who has had to retire owing to the pressure of his Parliamentary work. It has long been the custom that two out of the four Assessors to the Court should be medical men, Dr. Mackenzie Johnston being the other at present serving in this capacity. Sir Norman Walker and Dr. Mackenzie Johnston have many distinguished predecessors, amongst whom are numbered Sir Patrick Herron Watson, Sir Joseph Bell, and John Duncan.

University of Glasgow.

Students' Welfare Fund.—The week is marked by great University activity on behalf of the Students' Welfare Fund. Like other non-residential Universities and Colleges, that of Glasgow has, for the greater period of its existence, suffered from the lack of corporate life. Blame must to some extent be laid at the door of the national temperament. Academic honours open up more lucrative fields for their holders; too little attention has been given to the development of culture and character. The experiences of the war have drawn the attention of teachers and students alike to the broader issue; and to no faculty is the question more important than to that of medicine. The scheme includes the provision of hostels, larger unions, and adequate playing-fields, and the sum aimed at for this purpose is £150,000. Of this £70,000 have already been raised. Two hostels have been equipped; a new women's union has been bought and equipped; the playing-fields have been put in order, and plans for a new pavilion are under consideration. On Nov. 8th–10th the University staged a great bazaar, to be opened on successive days by Viscount Novar, the Lord Rector (Lord Birkenhead), and the Principal. The King and Queen accorded their patronage.

General Council.—At the half-yearly meeting the General Council approved a draft ordinance, which provides for the pensioning of principals and professors at the ages of 70 years and 65 years respectively. There was a good deal of discussion over the imposing of an age-limit. In summing up the matter, the Principal pointed out that young assistants would accept academic posts the more willingly if they knew that such an ordinance offered them greater possibility of promotion.

Glasgow Royal Infirmary: The Lister Ward.

The Council of the Incorporation of Architects in Scotland at their last monthly meeting decided to lodge a petition with the managers of the Royal Infirmary of Glasgow in favour of the retention of the Lister ward in the infirmary, thus supporting the action of the French Academy of Medicine and other continental societies. The appeals which have been presented to the managers, as published in the *Glasgow Herald* of Nov. 3rd, are signed not only by leading Glasgow citizens in every walk of life, but also by many distinguished members of the medical profession in England, America, France, Germany, Switzerland, and Denmark.

A charity matinée in aid of the building fund of the Glasgow Hospital for Diseases of the Ear, Nose, and Throat was given in the Pavilion Theatre this week. The theatre was granted by its directors, and artistes from various music-halls in the city contributed. Of 37 wards in the city, the Blythswood ward, under whose auspices the matinée was held, is the eighth or ninth to contribute to the support of the scheme.

The first meeting of the Glasgow Northern Medical Society was held recently, when Dr. A. Muir Crawford opened a discussion on Diabetes, with Special Reference to Treatment by Insulin. Drs. W. A. Allan, J. Donald, A. J. Hutton, R. Grieve, J. Todd, and Joseph Glaister took part in the discussion.

Out of a total of 390 panel practitioners in Glasgow 368 have resigned.

Aberdeen Medico-Chirurgical Society.

A clinical meeting of the Society was held on Nov. 1st, Dr. Alexander Ogston, the President, in the chair. Dr. W. F. Croll showed: (1) A child of 8 years with her heart on the right side. The electrocardiogram showed that the case was not one of dextrocardia, but the lung condition did not appear sufficient to explain the displacement; (2) a case of aortic stenosis with delayed conductivity and endocarditis lenta. Dr. Anne Mercer Watson and Dr. A. G. Anderson demonstrated two cases showing the late sequelæ of encephalitis lethargica which presented the syndrome of a mid-brain lesion. Dr. H. J. A. Longmore showed a case of acroparæsthesia—a man of 63, complaining of pain, swelling, and stiffness of the hands and lower half of both forearms while at rest; there was no alteration in sensation and the general physical examination was negative except for a persistently high blood pressure; the condition was relieved by active muscular movement. Treatment by vasodilators and other means, including high-frequency, had been without result. Dr. Longmore pointed out that the case was apparently the converse of intermittent claudication, and suggested as the diagnosis acroparæsthesia associated with vascular degeneration. Prof. Ashley Mackintosh read a note on a case of Brown-Séquard's paralysis of traumatic origin.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal Victoria Hospital, Belfast.

THE present session opened on Oct. 23rd, when there was a large gathering of students and of the medical and surgical staff. Mr. A. B. Mitchell, the chairman of the staff, presided, and in introducing Mr. Andrew Fullerton congratulated him upon his recent appointment to the Chair of Surgery in the Queen's University, and expressed confidence that he would fully maintain the high traditions of that chair. Prof. Fullerton, after welcoming the students, spoke of the motives which might prompt the choice of medicine as a career in life. Its financial rewards were in most cases on a modest scale. The profession suffered from injurious competition, and its prestige was often lowered by the conflicts of medical opinion. But for those who recognised its possibilities, it offered a career which could fully satisfy ambition. The pursuit of scientific medicine, the discovery of knowledge, the prevention of disease, the relief of suffering—these were its aims, and in the course of the prosecution of such ideals could be obtained the gratitude of fellow men, and just influence in society. Surgery had in recent years occupied a dominant position, but it was now being pressed hard by the bio-chemist, the radiologist, and the clinical pathologist. Medicine was making vast strides. The discovery of insulin had opened a new era in the treatment of diabetes. Radiology had not only thrown light upon many abdominal conditions, but had illuminated the brain, and advanced into the sphere of therapeutics. It gave some hope of the alleviation or cure of some forms of cancer. The treatment of wound shock had advanced far beyond the outlook in pre-war days. These results were the fruit of international coöperation in medical science, and it was the duty of all to recognise the fraternity of medicine. A provincial hospital must be regarded as a unit in a world-wide association. Research was a matter in which the general practitioner should play his part. Edward Jenner in past times and James Mackenzie in recent years had been general practitioners. The student must study and record his cases with industry and care, and regard his clinical notes as something more important than helps to pass his examinations. A hospital would be known by its records. In conclusion, Prof. Fullerton referred to the long and valuable services which Prof. T. Sinclair, who had become consultant surgeon, had rendered to the hospital and the medical school. He also congratulated Prof. W. W. D. Thomson on his recovery of health, and Dr. H. P. Malcolm on his appointment as assistant surgeon. A vote of thanks to Prof. Fullerton for his able address was passed on the motion of Dr. W. Calwell, seconded by Mr. J. A. Craig.

The staff of the hospital held their annual dinner in Thompson's Restaurant on Oct. 23rd. The staff was fully represented, and the following members of the consulting staff were present: Sir Walton Browne, Prof. Sinclair, Prof. J. A. Lindsay, and Dr. T. K. Wheeler. Opportunity was taken to make a presentation, in the form of an oil painting, "Littlehampton Harbour," by B. W. Leader, R.A., to Prof. Sinclair on his retirement from the active staff. Mr. Mitchell, who presided, referred to Prof. Sinclair's long term of office as professor of surgery in the Queen's University and surgeon to the Royal Victoria Hospital. To his influence and example the great developments of surgery in Belfast and the north of Ireland were in large measure due, and his personal character had been a great asset to the profession. Tributes to Prof. Sinclair's work and qualities were rendered by various speakers, and Prof. Sinclair suitably replied.

The Irish Dental Association.

A year ago the Irish branch of the British Dental Association became an independent body under the title of the Irish Dental Association. On Nov. 3rd, at the Shelbourne Hotel, Dublin, the association inaugurated its independent career by a dinner, when about a hundred members and guests were present. The President, Mr. J. Cockburn, was in the chair, and the Governor-General was principal guest. The President and Dental Secretary of the British Dental Association were present as guests to convey the good wishes of the parent body to its offspring. Among the other guests were the Minister for Local Government, the Vice-presidents of the Royal Colleges of Physicians and Surgeons, and the President of University College, Dublin. The Governor-General, in a happy and cordial speech, spoke of the pleasure it had given him at the recent opening of Parliament to anticipate as a measure of public health the dental care of school-children throughout the Free State.

"Audi alteram partem."

CENTENARY OF THE LANCET.

To the Editor of THE LANCET.

SIR,—Permit me to congratulate you on the entenary number of the London LANCET. This ournal was the handbook of my father during his life ime, and my brother and myself have taken it since ve have practised medicine. It is one of the most ighly valued publications in the library of the Mayo linic. We have on the shelves in bound volumes the omplete series.

Believe me, very sincerely yours,
Rochester, Minn., Oct. 22nd, 1923. W. J. MAYO.

To the Editor of THE LANCET.

SIR,—Allow me to congratulate you and your olleagues not only on the occasion of your Centenary, ut also on the splendid way in which it was commemorated by your Centenary number. It is, of ourse, a truism—but nevertheless a pleasant one—o repeat that in America, as elsewhere, THE LANCET s esteemed as one of the few great medical journals of he world, and it is correspondingly satisfactory to ee it flourishing so vigorously in its youthful old age.

As assistant editor of the *American Journal of Medical Sciences*, which celebrated its Centenary in 1920, may I be permitted to express the wish that THE LANCET may long continue to play its important ôle in interpreting medical thought to the medical rofession of the world.

I am, Sir, yours faithfully,
EDWARD B. KRUMBHAAR.
Assoc. Prof. of Pathology, Univ. of Penna.
Philadelphia, Oct. 20th, 1923.

To the Editor of THE LANCET.

SIR,—The Provincial Board of Health, Toronto, possesses an unbroken bound file of THE LANCET since 1861, and it is with great pleasure that I offer you most hearty congratulations upon the contents and general appearance of the Centenary supplement, filled, as it is, with a most interesting story of the progress of medical science of a century. No journal on this continent approaches the journal in the value and reliability of its weekly contents. May the next 100 years be even more successful than the last!

I am, Sir, yours sincerely,
JOHN W. S. MCCULLOUGH,
Oct. 22nd, 1923. Chief Officer of Health.

To the Editor of THE LANCET.

SIR,—May I add my tribute of congratulations upon the completion of the first century of a brilliant record of scientific work by your journal? I am only expressing the opinion of many of those engaged in the pursuit of research in obstetrics and gynæcology who have gained much stimulation and help from THE LANCET. You and your journal have done inestimable service in keeping up our British standard of scientific truth and excellence in medicine.

I am, Sir, yours faithfully,
Nov. 5th, 1923. A. LOUISE MCILROY.

To the Editor of THE LANCET.

SIR,—The editorial committee of the *Bristol Medico-Chirurgical Journal* hope that the editorial staff of THE LANCET will accept their very hearty congratulations upon the completion of that journal's hundredth year, and they trust that THE LANCET may continue in robust health, and may celebrate very many happy returns of its birthday.

I am, Sir, yours faithfully,
ARTHUR L. FLEMMING,
Bristol, Oct. 31st, 1923. Editorial Secretary.

To the Editor of THE LANCET.

SIR,—My heartiest congratulations on the occasion of the Centenary of THE LANCET. I send my greetings to the editors, proprietors, and managing staff of the paper. To them is due the immeasurable reputation that THE LANCET enjoys throughout the world where medical science is revered. THE LANCET is known not only where English is spoken, but wherever there are patients and doctors. Its articles and leaders being translated into all written languages, it is known to almost all medical men. THE LANCET has achieved in the first 100 years such a popularity and such a great responsibility that its name stands as familiar to all cultured men. Scarcely a day passes without a reference to THE LANCET in lay journals. In respect of a new medical discovery many lay journals, before forming a critical judgment, wait until THE LANCET has commented on the matter, knowing the weight, authority, and truthfulness of THE LANCET'S opinion.

I hold many posts, but of none of them am I so proud as of my pleasant connexion with this "great power" in medical journalism, as

YOUR BUDAPEST CORRESPONDENT.
Nagyvarad, Transylvania, Oct. 17th, 1923.

THE ACTION OF ALCOHOL ON MAN.

To the Editor of THE LANCET.

SIR,—Your review of Prof. E. H. Starling's book hardly does justice to its significance. From the evidence given in this book Prof. Starling is "convinced," as he says in the preface, "that in a civilised country such as ours the abolition of all alcoholic beverages from among our midst, even if carried out by universal consent, would be a mistake and contrary to the permanent interest of the race." It is "written from the purely scientific standpoint," and is intended for lay as well as professional reading. In consequence, a good proportion of the author's own chapters is occupied with an exposition of the elementary physiology of the various systems of the body. There is no attempt to survey the literature and there are no references which would guide the curious and critical reader to original sources. This is a pity, for though the publicity agents of "the Trade" will no doubt be content to hammer Pussyfoot with "Prof. Starling says" (and the teetotallers to hit back under the same authority if they can anywhere find a useful brick), there will probably be a certain number who would like to look further into the details, and the bibliography appended to Prof. Raymond Pearl's appendix deals only with a limited part of the subject.

The first 13 chapters (pp. 1–168) deal with the physiological and psychological effects of alcohol, its use as a food, its absorption and metabolism, the results of excess, and so on, and give a very readable account of generally accepted truths; the gist of them is that alcohol is a narcotic acting on the different levels of the brain from above downwards successively as its concentration in the body increases. Dr. Hutchison (pp. 177–182) gives an uncritical statement of the experience of a a physician on alcohol as a medicine in which its virtues in a variety of diseases are extolled and no mention is made of any disadvantages which may be experienced or precautions which should be taken. Sir Frederick Mott (pp. 183–212) takes an interesting survey of the relation of alcohol to mental disorders, pointing out that its ætiological importance in insanity has been a good deal exaggerated owing to the failure to recognise that persons with an inborn psychopathic tendency may become antisocial with quantities of alcohol which would have no effect on normal people. Finally, Prof. Pearl (pp. 213–286), in a contribution of a much higher critical order than the rest of the book, presents a detailed examination of the relation between alcohol and mortality, largely based on new data collected in Baltimore.

Prof. Starling's argument in favour of the moderate use of alcohol—for frankly once he passes beyond the statement of physiological fact he is arguing a case—is shortly that there is no evidence that it does anyone any harm and that he finds the evening meal is much jollier with it than without. Fortunately, he is clear as to what he means by moderate (p. 174); none on an empty stomach, 12 c.cm. of absolute alcohol or a glass of beer or a wineglass of claret with your lunch, and with your dinner 35 c.cm. or half a bottle of light wine, a pint and a half of ale, three ounces of whisky or a quarter of a bottle of port will not alter a man's powers of comporting himself with propriety; on occasions, indeed, "another little drop wouldn't do you any harm," but the rash man who takes the equivalent of 70 c.cm. is warned that he may be aware of it next morning. This is truly moderation; many a "moderate drinker" would call it abstinence, and few will want to dispute the conclusion that such quantities are in themselves almost or quite physically harmless to the individual who consumes them. Whether they are in fact without some slight effect is really almost impossible to determine. Prof. Starling himself says categorically that the quantities defined may be taken throughout adult life without interfering with bodily health or efficiency and appeals to Pearl's statistics. These show that the expectation of life of the "moderate and occasional drinkers" is probably a little better than that of the "total abstainers," while the "heavy and steady drinkers" have at all ages and in both sexes a far higher mortality. Prof. Starling (p. 157) parodies this into the summary that "any advantage as regards increased expectation of life lies with the moderate and occasional drinkers rather than with the total abstainers," and has apparently overlooked Pearl's explicit statements (p. 243) that while "total abstainers" include only those who have never taken any alcohol at all, "the person who made it a regular habit to take wine or beer with meals, even though the amount so taken was never excessive, was placed in the 'heavy or steady drinkers.'" Starling's moderation is therefore different from Pearl's, and the habits, unexceptionable in genteel circles in this country, defined by him as quite safe on pp. 174–5, would, in the Baltimore schedules, put a man into the most alcoholic category, the high mortality of which is the main fact brought out quite clearly in the figures. The "heavy and steady drinkers" no doubt included also many instances of gross excess, but the average wages earned were about the same in all three categories which suggests that the proportion of what in our English way we should call really heavy drinkers was not very high. The statistics, therefore, neither support nor refute Prof. Starling's proposition. He gives no other evidence in its favour. But it is one which is quite likely correct and is certainly easy to believe.

The second part of the argument is that a moderate amount of alcohol is actually beneficial because it paralyses the highest levels in the brain, anæsthetises a man from his worries, takes off some of his controls and inhibitions, and promotes good fellowship; the day's work is smoothed off by a placid evening and a good night's sleep and all is in better trim for going on again the next day. So impressed is Prof. Starling with the virtues of alcohol at the evening meal that the brilliant statement of them on p. 76 is supplemented by additional commendation in three other passages (pp. 99, 113, 154). In comment I can only say that though the book is, as the preface says, "written from the purely scientific standpoint," I do not believe that these particular observations have been adequately controlled. The day's work over, a clean cloth, flowers on the table, a congenial companion, and a good meal are all mixed up with alcohol into a jumble of variables. It is, in fact, quite common for teetotallers to have the same joyous experience without the alcohol with the same pleasant result, including the dance. As to the necessity of alcohol at the big dinner party, it is at least possible that no quite sane man would put up with such affairs, unless he was partly anæsthetised, any more than a Scotsman will eat a haggis without some raw whisky to cover up the taste. "The dull depression or the forced merriment of a teetotal party"—I assume that this is a correct summary of sufficient experience—are beside the point. They may be dull because there is no alcohol or because the people involved are inherently dull. Teetotallers as a class are apt to be a queer and cranky lot, and no serious student would pretend to measure the effect of moderate drinking by comparing total abstainers with abstemious drinkers as they have existed in this country in the last 20 years. Spontaneous wild drinking and complete abstinence are each associated with a particular make-up of body, soul, and spirit, as Prof. Starling points out himself (p. 158), and he will surely realise that in comparing teetotallers with average men he is trying again to deal with several variables at once. However, even if his argument will not bear any critical examination, it is easy to allow that Prof. Starling represents a common experience; dinner is pleasanter with alcohol than without.

The moderate use of alcohol is therefore beneficial. From which the author proceeds to the conclusion that national abstinence by common consent would be a mistake. A great many people would agree with him in believing that life would be a more meagre experience without alcohol, and their opinion, like his, would in most cases be founded on wholly inadequate data. Many of them would realise with him that the excessive use of alcohol "is the cause of a large amount of disease, crime, misery, and inefficiency," and that to a use which in common judgment is by no means immoderate is due a mass of stupidity, indecency, and unkindness which the world could well do without. And when they come to strike a balance of the pros and cons, some of them are content to lose their alcohol for the sake of the weaker brethren. Prof. Starling is not; he is not even content to let everyone give it up by universal consent. As befits a great university teacher, he believes that alcoholism is to be cured by improvements in education and social conditions. And meanwhile, under the influence of precisely graduated doses, young men will continue to unburden their souls at the dinners of the Physiological Society, and old men will rashly promise donations to hospitals, and the teetotallers will sit in their dull depression.

The book is unworthy of its author. With the exception of Prof. Pearl's contribution, it contains nothing new, and the general state of physiological knowledge of the effects of alcohol on man was at least as fully, if less vivaciously, stated in the 1918 report of the Liquor Control Board, which could, I think, be had for 1*s.* instead of 12*s.* 6*d.* The reasoning is slipshod and the final conclusions, drawn from "the purely scientific standpoint," have no more "scientific" validity than the impressions of the man in the street; they would be equally "unscientific" if they were the reverse of what they are, and it would be equally a pretence to dress them up as the necessary deductions from precise physiological knowledge. Prof. Starling's verdict may or may not be correct; my point is that if it is, it has been arrived at by intuition or prejudice or some other accessory to practical life; it is not the result of any evidence which he sets out.

I am, Sir, yours faithfully,

CHLORATE OF POTASH IN ENURESIS.

To the Editor of The Lancet.

Sir,—In the valuable article, No. XXXV. i your series on Modern Technique in Treatmen (Sept. 8th), by Dr. Hugh Thursfield, the write says he cannot tell why chlorate of potash shoul be useful in enuresis. Some 20 years ago I saw in the "Year Book of Pharmacy" that a larg percentage of chlorate of potash passed unchanged int the urine. I have consequently always been alert t recognise that we affect the mucosa of the urinar tract when we exhibit chlorate of potash by mouth. Again, the fact has been ever present to me on applying the indican test to a sample of urine, lest by potassium chlorate in excess it should fog the indican test, giving a negative reaction instead of a positive one.

I am, Sir, yours faithfully,
J. BARKER SMITH, L.R.C.P.
Herne Hill, S.E., Nov. 1st, 1923.

THE RESULTS OF MAMMARY CANCER OPERATIONS: A COMBINED INQUIRY.

To the Editor of THE LANCET.

SIR,—The Medical Society of London have appointed a committee of surgeons to investigate the later results of operations for cancer of the breast. The scope of the inquiry at present is being limited to cases of patients who are known to be alive not less than ten years after the primary operation for undoubted cancer. A preliminary inquiry has already brought to light the existence of a number of such cases, and the Society is therefore encouraged to make a wider appeal. The committee would be obliged if any medical practitioner, who has not already been approached, having personal knowledge of any such cases would communicate with the hon. secretaries of the Society.

We are, Sir, yours faithfully,
T. P. LEGG,
F. LANGMEAD,
Hon. Secretaries, Medical Society of London.

THE ALBUMINURIA OF PREGNANCY.

To the Editor of THE LANCET.

SIR,—I did not know before reading Prof. F. Cook's letter in your issue of to-day that at times the albuminuria of pregnancy may be of uni-renal origin. He mentions one case in which "urine from the left kidney was loaded with albumin," whilst "that from the right contained the merest trace." The idea is quite new to me; the occurrence, presumably, must be attributed to structural peculiarities, such as Dr. J. W. Russell (in your issue of Oct. 27th) adduced in explanation of his cases of unilateral œdema affecting the lower extremities. In pregnancy, with the rise of the intra-abdominal pressure, such factor for the first time must have come into prominence, otherwise the albuminuria must be imputed to have existed before. It is interesting, however, to observe that so far in his observations, the albuminuria of pregnancy is more usually bi-lateral, "although in several instances . . . very considerably more albumin" has been found coming from the left than the right kidney. From this it is plain that if the course of the left renal vein (from the renal hilum, across the spine in front of the aorta to the cava), and its disposition (at right angles) associated with the lordosis—natural in advanced pregnancy—is the cause of the greater leakage of the left kidney, since on the right side such factors are absent and yet albumin in the right renal urine occurs, such disposition cannot be the only or the pre-eminent factor in the albuminuria of pregnancy.

It was supposed by those who did me the honour of discussing my paper on Eclampsia and Its Incidence at the Royal Society of Medicine (1921)[1] that in advancing a mechanical explanation of eclampsia, I was simply reverting to Lever's idea (1843). Lever supposed that puerperal convulsions occur because the kidneys become inefficient from obstruction of their veins. My idea is quite different: it is that the blood-flow through the renal *capillaries* is obstructed and ultimately stopped by the physical changes which occur in some cases of pregnancy. I came to this opinion from my study of the levator ani muscles. I saw that these muscles act simply as a pressure-resisting mechanism, and that the pressure they help to sustain is essential to normal metabolism. In man, with a persistent diminution of this pressure, we get a diminished metabolic rate with resulting weakness—physical and mental (neurasthenia)—whilst with its too great increase, as occurs at times in pregnancy, the excretory organs (liver and kidneys) are prevented from functioning efficiently by circulatory obstructions. These, in my opinion, explain eclampsia; the fact that in the albuminuria of pregnancy no "definite deviation whatever from the normal, with the possible exception of œdema" occurs, does not vitiate this explanation; it supports it. The occurrence of such albuminuria without any sign, "clinical" or "biochemical," of deviation from the normal is in line with my conception; it is just what we should expect. But no one can believe that with albuminuria the kidneys are normal, even though a return to normal should subsequently occur. With treatment the albuminuria of pregnancy passes away, without it the change in the kidney and liver not uncommonly proceeds to that disorder of which a blood change is the natural result, and convulsions the only expected ultimatum.

The publication of Prof. Cook's inquiry, when completed, will be looked forward to with expectation. Whilst thanking him for referring to his work at this early stage, I venture to warn him of the danger of imputing the albuminuria of pregnancy to mechanical causes; such can only lead to the belief that eclampsia itself is similarly caused.

I am, Sir, yours faithfully,
R. H. PARAMORE, F.R.C.S. Eng.
Brook-street, W., Nov. 3rd, 1923.

THE LISTER WARD IN GLASGOW ROYAL INFIRMARY.

To the Editor of THE LANCET.

SIR,—The inherent courtesy of Dr. Freeland Fergus's letter to THE LANCET of Oct. 27th almost disarms criticism. None the less, may I venture to think that the real issue is, after all, the ever-recurring old-time issue, what to destroy and what to conserve—the claims of the past and the needs of the present. These, indeed, frequently conflict, but when there exists the desire there is sometimes found also a middle way wherein very often these issues may be reconciled. In this instance, on the one hand, there dominates the unique and immeasurable value of the famous ward; and pertinently thereto, may I quote part of a letter of Oct. 13th from Colonel Washburn, director of the Massachusetts General Hospital, U.S.A. Writing of the old operating room of his hospital where, on Oct. 16th, 1846, ether was first given to full surgical anæsthesia, Colonel Washburn says: "This room is kept as a surgical shrine, which is of great interest and value to the medical profession of America, and we hope to the medical profession of all the world." Of how much relatively greater value is the Lister ward? Sir Thomas Oliver, of Newcastle-upon-Tyne, who has just returned from visiting the hospital named, told me that a memorial lecture is delivered in the theatre once in each year. Dr. Albert J. Ochsner, writing by the same mail from Chicago in favour of preservation, concludes his letter: "I believe that the sentiments expressed represent the feeling of the surgical profession the world over, and I sincerely hope that your argument may have the result of retaining the Lister ward." When Admiral Sturdee was lately in Glasgow, seeking funds for the preservation of Nelson's old ship, the *Victory*, he uttered words apposite also to the Lister ward: "It's value for recruiting purposes, for encouraging the sea instincts of the race, and as an inspiration for the future as well as a memorial of the past, is beyond all reckoning."

On the other hand, it is, of course, at once and readily admitted that the real infirmary requirements of to-day hold their own important and essentially necessary place. What, however, these requirements are, and the manner in which it is proposed to meet them, are known only to the infirmary managers and staff; but

---

[1] THE LANCET, December, 1921.

I may venture the opinion after almost 50 years' experience of planning, that given goodwill and the desire to meet the various needs and interests, I have never once seen a planning problem that could not be solved. A new and even great dispensary will, within measurable time, become obsolete and require replacement, but the Lister ward properly envisaged will become of increasingly greater value as the years come and pass away. It may have been, and I believe was, the original intention of the managers to remove the ward and leave the site open; but to build upon the site as is now proposed must be an afterthought, for the original elevations do not show any such purpose or intention. Why, then, this sudden change? The Lister ward occupies the very narrowest angle of the ground proposed to be utilised for the new dispensary, and, therefore, might surely and not unreasonably be spared. To build upon this small portion of ground is to go back also upon the managers' own original argument against the retention of the one-storey Lister ward—viz., "that it would to some extent interfere with the free circulation of light and air to the new buildings." If, therefore, not one but two-storey buildings are proposed to be erected upon the site of the ward, surely the evil alleged will only be intensified; and it may respectfully be asked, Do the new buildings proposed solve the managers' difficulties in the best, or, indeed, in the only possible way? Lord Rosebery once aptly summed up the matter in a somewhat analogous case when he affirmed, "What is wanted is not an engineer to condemn, but an engineer to preserve."

May it not be that the managers are somewhat obsessed with the idea "of a new and thoroughly up-to-date dispensary for the out-of-door patients," to which all other things must be sacrificed? Monuments of "historic interest" may not directly help towards the "alleviation of sickness and distress"; but they go a very long way, alike in being and inspiration, to the encouragement of others in the benign service of humanity, whether that service is rendered by individuals or by the staffs of great institutions. These monuments remain sermons in stone and ringing trumpet calls, animating to great deeds, long after the human voice of the preacher or leader has passed away. In surgery, are such buildings not the battle emblems of the great army of healers, impelling to emulation in sacrifice and heroism; in arduous, always beneficent, and often dangerous work? Wherever, in the many places in which Lord Lister carried on his researches, even from student days in University College, London, it yet remains that the Lister ward is the one and only place in which these researches actually and first touched suffering humanity. It was in the very ward which it is to-day hoped to preserve that the hopelessness, the despair, and the agony, not only of the patients in the ward, but of suffering humanity throughout the wide world first saw the morning dawn of hope, relief, and life.

With all deference, and sincere deference, to Dr. Freeland Fergus's position and views, is he not in his loyalty to his colleagues valiantly reasoning to try by just a little to make the worse appear the better cause—hence, his many and obvious perplexities? In his heart I think he agrees with me, that the real question is not the erection of a great dispensary, but whether the Lister ward is to be regarded as at best but a pertinent of the Glasgow Royal Infirmary or as a great national and world memorial and heritage.

I am, Sir, yours faithfully,
JAMES A. MORRIS.
Ayr, Oct. 31st, 1923.

THE WORK OF THE TUBERCULIN DISPENSARY LEAGUE.

To the Editor of THE LANCET.

SIR,—There are several passages in the introductory remarks to the report on the work of the Tuberculin Dispensary League in THE LANCET of Nov. 3rd (p. 984) to which I might fairly take exception; but I am sure that everyone knows that in a highly controversial subject the knocks on gives and takes are not the real thing that matter and should not be allowed to obscure it.

May I hope that our pamphlet may be now rea as a commentary on the report rather than as a attack upon it, and that all who are interested i the check of tuberculosis will read both together, an form their own conclusions as to the efficacy of D Camac Wilkinson's method. Particularly I woul refer them to Dr. Stobie's figures, printed as a appendix, which are altogether outside the con troversy. I am quite willing to reprint it with an reasonable modifications desired.

I am, Sir, yours faithfully,
RANDALL DAVIES.
Cheyne-gardens, S.W., Nov. 5th, 1923.

VICTOR HORSLEY LECTURE: THE LATE PROF. JOHN MARSHALL, F.R.S.

To the Editor of THE LANCET.

SIR,—I am sorry my old friend, Sir John Tweed should think that my remarks about Marshall we cruel and intended to disparage him. My intentio was simply to compare him and Lister, and I cou not help making the comparison into a contrast, pointing out what a serious mistake was made by th Council of University College in preferring his clai to those of Lister. That Marshall was a good surge of the old school, that he was of the highest characte and had a charming and gentle personality, all wh knew him would agree. But the fact remains that h failed to appreciate the new surgery introduced b Lister, which was enthusiastically taken up by th younger men, such as Marcus Beck. It is not want disparagement to say this, merely the truth. Marsha was by no means alone; I doubt if a single seni surgeon in London adopted Lister's methods f many years after they were promulgated.

I am, Sir, yours faithfully,
E. SHARPEY SCHAFER.
Edinburgh, Nov. 6th, 1923.

PRIVATE WARDS IN LONDON HOSPITALS

To the Editor of THE LANCET.

SIR,—In reference to the article contained in th last issue of THE LANCET I am writing to point o that the Victoria Hospital for Children has priva wards containing a total number of 14 beds. Visit may attend daily. By opening this home the co mittee believe that they are supplying a much-need want, and that many parents will be glad to secu for their children the treatment, nursing, and oth advantages of a leading institution. The home adjacent to the institution, which itself is situated the quiet residential district of Chelsea, and the priva wards overlook open grounds many acres in exten There is a separate kitchen and kitchen staff. T terms are £1 per day or £5 5*s*. per week. Wh admitted the patient must be under the care of consultant of one of the recognised hospitals of Lond The attendance of the hospital's resident medi officer is free of charge.

I am, Sir, yours faithfully,
D. ST. JOHN BAMFORD,
Secretary, Victoria Hospital for Children,
Chelsea, S.W.
Nov. 5th, 1923.

*** We welcome the information contained in th letter. The list given in our last week's issue purport mainly to show what accommodation in private wa was available for adults.—ED. L.

NEW YORK LARYNGOLOGICAL SOCIETY.—T coming celebration of the fiftieth anniversary of the found of this society, which will take place on Nov. 15th, co memorates an event of unusual interest. As far as can learned, this organisation, now the Section in Laryngol of the New York Academy of Medicine, is the oldest soci in existence of the department which it represents. connexion with the celebration there will be an exhibit representing the important contributions made to progress of laryngology in the city of New York.

Obituary.

PETER WALLWORK LATHAM, M.D. CAMB., F.R.C.P. LOND.,

LATE DOWNING PROFESSOR OF MEDICINE IN THE UNIVERSITY OF CAMBRIDGE.

WE regret to announce the death of the venerable Prof. Peter Wallwork Latham, senior Fellow of the Royal College of Physicians of London, which occurred at Clifton on Oct. 29th, a few days after his ninety-first birthday. With him passes a great physician, teacher, and personality; double first in class lists, university professor, consulting physician, and keen pathologist, he was throughout his very prolonged life an outstanding figure in the medical profession.

Latham was the eldest son of a Lancashire general practitioner, and went while quite young to the University of Glasgow, whence he obtained a scholarship at Gonville and Caius College, Cambridge. There he graduated as a wrangler, and in the following year divided with Prof. George Henslow, the eminent botanist, the honour of composing the first class in the Natural Science tripos. He then studied in Germany, and for a brief period was assistant physician to the Westminster Hospital, but quite soon, and some 60 years ago, he returned to Cambridge as Fellow of and medical lecturer at Downing College, being at the same time elected physician to Addenbrooke's Hospital and University reader in medicine. In 1874 he was appointed Downing Professor of Medicine, a chair which he held for 20 years.

His association with Downing College was long and fruitful. On his election to the Society the College was in a very bad way. Sir George Downing, a local baronet with an odd family history, had left a will directing trustees, failing the establishment of next of kin, to purchase land and erect a college at Cambridge bearing his name. The will was made in 1717 and was proved at his death in 1749, when the relatives were dead without issue, and the trustees were all dead also. Profuse litigation resulted. It was not till 1769 that a judgment was obtained that the trusts should be carried into execution, but the estates were in the possession, illegal it would seem, of the devisees of Downing's widow, and the charter for the College was not obtained until 1800, 83 years after the will was made. Starting in such circumstances and with the estate immediately crippled by building, the College nearly died before it lived; practically no undergraduates matriculated, and the College consisted of two or three Fellows and a group of Fellow-commoners. Latham, upon election as a Fellow, devoted time and great business capacity to the drafting of new statutes, thus bringing the College up to a good position in the University, while the establishment of professorships in law and in medicine secured from the beginning the adherence of a certain number of distinguished men.

Prof. Latham's association with the Royal College of Physicians of London was very close and distinguished. He became a Fellow in 1866, and 20 years later was elected to the Council, being the first provincial physician to serve on that body. In that year he delivered the Croonian lectures, taking as his subject the pathology of rheumatism, gout, and diabetes. These lectures, which were published in our columns, endeavoured to indicate the changes in the nervous system, the blood, and the tissues which may take place in the three diseases, and their text was furnished by a suggestion from Sir James Paget that "disturbance in the nervous system in some form and part may be regarded as a fact in every case of gout." Applying similar generalisations to rheumatism and diabetes, Latham illustrated his theory of their pathology with far-reaching clinical references and in particular with elaborate chemistry. He was a Censor of the College in 1887–89, and in 1888 was appointed Harveian Orator, when his oration, which was published in THE LANCET,[1] was a highly interesting plea to working pathologists to search out the secrets of medicine by way of experiment. He paid his tribute to Harvey by dwelling upon the latest advances in pathological knowledge, saying that they had been gained by the simple, patient investigation of nature which Harvey had pointed out as the guiding principle of all genuine seekers after truth, and his philosophic discourse was well calculated to quicken the spirit of investigation.

Prof. Latham was in practice in Cambridge for half a century, and on leaving the city in 1912 received a remarkable series of presentations from the medical men in the neighbourhood. He was twice married, first to the daughter of John McDiarmid of Dumfries, by whom he had two sons and one daughter, and secondly to the daughter of the late Dr. J. F. Bernard of Clifton. Prof. Latham's daughter, who survives him, is the wife of Lord Clyde, Lord-Justice-General of Scotland, but his two sons predeceased him, one, a soldier, dying from injuries received at polo, the other being the late Dr. Arthur Latham whose great loss to British medicine we have recently sustained.

PERCY WHITTINGTON SAUNDERS, M.B. TORONTO, F.R.C.P. LOND., M.R.C.S. ENG.

Dr. Percy Saunders, who died on Nov. 1st, had already been ill for some time, when a flare-up of his disease about six months ago necessitated complete rest from his numerous activities. Born in Toronto in 1877, Saunders took his B.A. degree in that city in 1898 and his M.B. in 1902, when he also gained the gold medal. Coming to this country in pursuit of extended knowledge and experience, he worked for some time at the London Hospital and took the M.R.C.S., L.R.C.P. diploma in 1905. He also held several appointments at the Victoria Park Chest Hospital and at the Shadwell Children's Hospital. He then went to the National Hospital for Paralysis and Epilepsy, Queen-square, where he was first house physician and resident medical officer, and later registrar, being afterwards appointed on the staff as assistant physician. He was also physician to the Royal Free Hospital and was elected F.R.C.P. in 1917. He was an excellent teacher and a hard and industrious worker; the strain imposed on him during the war, when he was often doing two or three men's work, must have made excessive demands on his strength, and probably undermined his resistance and paved the way for the onset of his fatal illness. Naturally modest and retiring, Saunders was not a man of many friends, but those who knew him well soon recognised, beneath his quiet and somewhat deprecatory manner, the sterling character of the man, and the solidity and soundness of his judgment in medical matters, founded as it was on a wide and deep acquaintance with clinical medicine and medical literature. His hospital rounds were marked by a wise deliberation and by great kindness to his patients. His early training had also imbued him with classical knowledge and a taste for classical literature, and although he did not write much, what he did write was characterised by clear thinking and lucid and tasteful expression.

Dr. Saunders will be greatly missed by colleagues, students, and patients alike, and much sympathy is felt with his parents in their distant home, all the more in that they lost another son in the war.

WILLIAM HALL, M.R.C.S. ENG.

THE death of Dr. William Hall, at the age of 89, took place recently at Headingly. Seventy years ago he began his professional career as apprentice to Dr. Samuel Radcliffe, of Leeds. After studying at Leeds Medical School and Guy's Hospital, Dr. Hall became M.R.C.S. and L.S.A. in 1855. He was for some time lecturer on midwifery and diseases of women and children in the Leeds School of Medicine and Surgery, and a surgeon at the Leeds Hospital for Women and Children. He was the founder of the Leeds Barefoot Mission which preceded the "Boots for the Bairns"

---

[1] THE LANCET, 1888, ii., 1715.

Fund, and long before the question of feeding necessitous school-children was raised in Parliament he was a pioneer in this work. His work as a factory surgeon in the "seventies" made him familiar with the needs and requirements of child workers, and one of his great objects in life was concern for the improvement of the health and physique of children. Retiring from active practice in 1902, the next ten years of his life were devoted to a continuation of his efforts for the promotion of the social well-being of the community. In 1905 his practical effort found expression by supplying 60 poor school-children with half a pint of milk and a bun each day, much to the improvement of their health, and later on the scheme was extended, so that breakfasts and dinners were supplied to 100 school-children. Within a short time he raised £1000 for this purpose, and thus anticipated by 15 years both the medical inspection and the feeding of school-children by the State. Dr. Hall leaves two sons and one daughter; the elder son is Dr. Robert H. Hall, of Leeds, who succeeded to his father's practice, and the second son is Mr. John Basil Hall, honorary consulting surgeon to the Royal Bradford Infirmary and President-elect of the British Medical Association.

THE LATE DR. G. D. MAYNARD.

WE briefly noted last week the untimely death at Johannesburg of Dr. George Darell Maynard and the loss entailed to statistical medicine. Dr. Major Greenwood writes:—"The news of Dr. Maynard's death is very grievous. He was unquestionably one of the foremost medical statisticians in the world, and a paper published as recently as last March[1] showed that, although he was no longer able to devote the whole of his time to research, we might expect a long series of important contributions from his pen to statistical science. Maynard not only had a thorough grasp of mathematical principles (as shown in a joint paper by himself and Dr. Troup on a very technical point of mathematical theory), but great critical powers. His earlier work on the statistics of anti-typhoid inoculation, and more recent studies of pneumonia, were good examples of the application of statistical canons of criticism. In his work on cancer and diabetes a flair for original investigation was manifest. Maynard's demonstration of a high correlation between the death-rates of cancer and of diabetes in American experience was a remarkable piece of work. The whole field was worked over again by Prof. Karl Pearson and Dr. Alice Lee, and also by the late Frances Wood and myself. The most sedulous re-examination of the data failed to reveal any error in Maynard's work, and the interpretation of his results must still be looked for; it is clear that the results are correct. It was an immense gain for biometric science that a man who had had wide clinical experience should devote himself to statistical inquiry. Maynard and Dr. John Brownlee were, in fact, the only medical statisticians of the first rank who had had such experience. The loss is irreparable. It is the more bitter in that Maynard's personal qualities endeared him to all who knew him. He was no dry-as-dust manipulator of figures, but a delightful companion. The statisticians in the National Institute of Medical Research will never forget the visit he paid us last year and his stories of campaigning experiences in the war. The loss is indeed irreparable, but yet the future of a branch of science that can arouse the enthusiasm of such a man is assured. We are the poorer by his loss, but his example has given us courage to go on."

MEMORIAL TO THE LATE DR. H. D. FARNELL.—A committee has been formed to consider the form of the memorial to Dr. Farnell, under the presidency of the Mayor of Eastbourne, Councillor G. B. Soddy. It is hoped that a sum of £10,000 may be raised, and though the nature of the memorial has not yet been decided on, it will probably be in association with Princess Hospital, to which Dr. Farnell was for long attached.

Medical News.

UNIVERSITY OF OXFORD.—In a Congregation hel on Oct. 18th the degree of Bachelor of Medicine was conferred on T. A. Brown, Exeter College.

The Whitley Professor of Biochemistry, Dr. R. A. Peters, will deliver an inaugural lecture in the Examination School on Wednesday, Nov. 14th, at 5 P.M., the subject bein A Wonderland of Chemistry.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AN SURGEONS OF ENGLAND.—At the Final Examination hel from Oct. 2nd to 26th the following candidates wer approved in the undermentioned subjects:—

Medicine.—M. V. Abraham, Manchester; Iris I. G. Adams, Royal Free and St. Mary's; J. N. Alexander, Guy's; A. E. Austen and R. T. Bannister, St. Bart.'s; J. Bee, London; E. R. Bennion, Westminster; C. E. W. Bower, Manchester; Annie Bryce, Birmingham; H. D. Chalke an J. H. H. Chataway, St. Bart.'s; M. N. Chatterjee, Birming ham; R. Chester, Leeds; R. G. Cochrane and T. S. Cochrane, St. Bart.'s; A. Cooke, Liverpool; A. M. Cooke, St. Thomas's; Rosemary Cooke, Charing Cross; Elizabet M. Cowie, Royal Free; G. I. Davies, Univ. Coll.; T. Davies, St. Bart.'s; Dorothy L. C. Day. London; A. M. Deane, St. Thomas's; J. A. F. Denyssen, Guy's; C. J. C. De Silva, Middlesex; B. Dous, St. Bart.'s; J. Dreadon Otago; C. L. Elgood, St. Bart.'s; V. H. Ellis, London Sarah Evans, Charing Cross; H. P. Goldsmith and A. W Grace, Univ. Coll.; C. W. Greenaway, Guy's; A. B Griffiths, Liverpool; L. W. Hale, Univ. Coll.; C. S. Hall pike, Guy's; J. F. S. Hamilton, Bristol; Leila M. Hawksley Royal Free; Margaret R. Herford, Royal Free and St Mary's; E. W. Hicks, St. Thomas's; Gabrielle M. Highfield Jones, Charing Cross; H. A. Hirst, London; Margare Hossell and Dorothy P. Hytch, Royal Free; D. E. Joscelyn and P. C. Joscelyne, Bristol; A. K. Kerr, St. Bart.'s H. B. L. Levy, Durham; G. Lucas, London; Kathleen M Lyons, Univ. Coll.; N. W. MacKeith, Guy's; J. R. A Madgwick and Dorothy B. Marling, London; K. F. T Mills, Middlesex; H. S. Morley, Univ. Coll.; L. Morris Manchester; E. V. Newling, Middlesex; I. Newton Charing Cross; Frances L. Nichol, Royal Free; R. D Owen, Guy's; C. Panchalingham, Ceylon; Isabel D Patterson, London; J. F. Payan, Guy's; Eleanor M Pulleine, St. Mary's; W. A. Robb, St. Bart.'s; F. Robinson Manchester; S. C. Rowbotham, Guy's; R. W. Savage St. Bart.'s; F. L. Scott, King's Coll.; F. A. H. Simmonds St. Bart.'s; T. H. Sims, St. Thomas's; A. E. Slinger King's Coll.; Beatrice M. Smyth, London; W. R. Spurrel Guy's; R. H. Stanbridge, London; E. B. Strauss, King Coll.; A. K. Thomas, Univ. Coll.; K. W. Thorp, St Thomas's; R. J. Toleman, Cardiff and London; B. D Underwood, London; B. M. R. West, Middlesex; H. J. W J. Westlake, Guy's; H. A. M. Whitby, St. Bart.'s; Joyc E. M. White, London; G. W. Wigg, Durham; R. C Williams, Birmingham; and Cicely F. Wilson, Bristol.

Surgery.—C. F. Ashby, St. Bart.'s; J. Atkin, Guy's Muriel E. Binns, Royal Free; R. A. Brews, London W. Brockbank, Cambridge and Manchester; R. E. D Cargill, St. Bart.'s; Nora Cheney, King's Coll.; R. Chester Leeds; H. G. Close, Guy's; T. S. Cochrane, St. Bart.'s Catherine A. Cowan, Royal Free; Vera Cullwick, Birming ham; Charlotta D. N. De Wilde, London; C. K. D Edwards, Liverpool; G. Elliot and J. Elgood, St. Bart.'s N. J. England, Bristol; T. J. Evans, Middlesex; G. H Froggatt, Sheffield; D. Frost and I. Gluckman, London W. E. Grice and G. J. Griffiths, Middlesex; C. S. Hallpike Guy's; J. G. Hamilton, London; Greta Hartley, Roya Free; R. C. Hatcher, Bristol; E. F. Hewlitt, Guy's J. A. Hislop, Durham; H. Jaffe, Manchester; A. T. Jones Univ. Coll.; I. S. Jones, Liverpool; E. F. King and F Langford, Bristol; N. E. Laurence, St. Bart.'s; O. B Lean, Univ. Coll.; R. R. Macintosh and H. Maclachlan Guy's; H. B. Mann and F. B. Matthews, Middlesex W. W. McLean, St. Thomas's; M. Meyers, St. Bart.'s S. M. Milner, Manchester; W. E. Moody, St. Mary's L. Morris, Manchester; C. J. Murphy, Birmingham; T. J O'Donnell, London; L. E. Owen and W. F. Payne, Guy's M. S. Pembrey, St. Bart.'s; M. Rubinstein, Guy's R. W. Scarff, Middlesex; M. B. Seng, Guy's; H. Sheard Leeds; N. Smith, St. Bart.'s; R. S. Starkey, St. Thomas's C. R. Steel, St. Bart.'s; E. G. Steeler, St. George's; D. M. E Thomas, St. Mary's; J. H. G. Thompson, St. Thomas's C. A. Van Rooyen, London; L. J. Watkins, St. Thomas's Dorothy A. Waterfield, London; Fanny M. Whittaker Charing Cross; T. M. Wilks, King's Coll.; and B. H. H Wooderson, London.

Midwifery.—S. Abadir, King's Coll.; N. J. Ainsworth Middlesex; G. T. Allerton, London; Kathleen D. Arnsby Royal Free; R. N. Aston, St. Bart.'s; Kathleen J Atkinson, King's Coll.; H. Aukland, Liverpool; K Bandaly, Univ. Coll.; R. T. Bannister, St. Bart.'s; M Bannounah, Guy's; D. T. Barnes, St. Bart.'s; E. V Barnes and J. C. Barrett, St. Thomas's; I. M. Benjamin Guy's; A. G. Bewes, St. Thomas's; Muriel E. Binns Royal Free; Phyllis E. Bond, Univ. Coll.; H. B. Boucher St. Thomas's; Margaret Bowstead, Royal Free; W. H Bradley, Guy's; Stella M. Brown, King's Coll.; Anni Bryce, Birmingham; Hilda L. Byett, Royal Free; A Canard, Guy's; K. Chaudhri, St. Mary's; C. F. Chissell Middlesex; Edith I. Clark, Univ. Coll.; W. Clark, Charin

Cross; G. C. W. Clarke, Sheffield; Winifred M. Clement, Charing Cross; R. G. Cochrane, St. Bart.'s; C. D. Cogswell, King's Coll.; I. Cohen, Middlesex; G. E. C. Collis, Univ. Coll.; C. K. Colwill, Guy's; A. Cooke, Liverpool; H. A. Cooper, King's Coll.; A. B. Cowley, St. Bart.'s; Vera Cullwick, Birmingham; D. V. Davies and J. R. Davies, St. Thomas's; L. F. Davies, Guy's; L. Davies, Liverpool; C. H. Devereux, Univ. Coll.; Georgina R. Dunn and Lorna Dunn, Bristol; J. D. Durance, St. Mary's; Kathleen H. Durance, Royal Free; R. H. Dyer, King's Coll.; R. M. Ealand, Bristol; J. T. R. Edwards, St. Bart.'s; L. C. Edwards, London; Mary G. H. Edwards, St. Mary's; W. Egan, Charing Cross; A. Elliot Smith, Univ. Coll.; N. J. England, Bristol; Phyllis V. L. Epps, Royal Free; Ann C. Evans, Cardiff; T. I. Evans, St. Thomas's; T. P. Evans, Charing Cross; S. A. M. Fam, King's Coll.; Edith M. Field, Royal Free; L. Freeman, St. Thomas's; W. S. Fricker, King's Coll.; A. T. Fripp, Guy's; E. B. Garrett, Univ. Coll.; P. Garson, St. Bart.'s; D. R. Gawler, King's Coll.; P. L. Goitein, St. Mary's; A. W. Grace, Univ. Coll.; H. Graf, Liverpool; F. H. K. Green, St. Bart.'s; F. N. Green and A. B. Griffiths, Liverpool; H. Hamilton, London; N. W. Hammer, Middlesex; Gabrielle M. Highfield-Jones, Charing Cross; C. G. Harper, Middlesex; I. Harris, Westminster; J. Hartsilver, St. Bart.'s; N. H. R. Hatfield, St. Mary's; Leila M. Hawksley, Royal Free; J. B. Hayes, Charing Cross; L. I. Henzell, Univ. Coll.; W. A. Hervey, St. Bart.'s; E. W. Hicks, St. Thomas's; A. C. Hill, Univ. Coll.; J. A. Hislop, Durham; R. G. Hodder, St. Thomas's; J. Holmes, St. Bart.'s; Barbara M. Hope, King's Coll.; D. V. Hubble, St. Bart.'s; W. Hughes, Middlesex; R. G. W. Husbands, Univ. Coll.; Dorothy P. Hytch, Royal Free; M. H. Jacobs, Guy's; H. N. James, St. Mary's; I. L. Johnstone, Middlesex; A. T. Jones, Univ. Coll.; A. Jowell, Guy's; L. C. Kalra, Charing Cross; A. C. King, London; G. M. King, King's Coll.; A. H. Kynaston, St. Bart.'s; G. S. Landon and S. A. Leader, Guy's; C. H. Lee, London; H. Levit and F. J. Levy, Guy's; H. B. L. Levy, Durham; H. M. Levy, Middlesex; E. I. Liberman, Guy's; E. O. Lloyd, Middlesex; H. Lord, Univ. Coll.; G. Lucas, London; G. A. McKaig, St. Thomas's; N. W. MacKeith, Guy's; A. V. Mackenzie, St. Bart.'s; J. H. Macpherson, King's Coll.; G. S. Malik, Univ. Coll.; Marion A. N. Marshall and Nancy S. Marshall, St. Mary's; E. L. Martin, Charing Cross; R. Massingham, Univ. Coll.; J. H. Matthews, Manchester; W. A. Mill, Guy's; A. J. Moody, St. Bart.'s; V. M. Morris and S. G. Mozumder, Middlesex; M. Murad and C. J. Murphy, Birmingham; W. R. Nash, St. Bart.'s; T. K. Natesan, Madras and London; E. V. Newling, Middlesex; C. T. Norris, London; K. C. L. Paddle, St. Bart.'s; C. Panchalingham, Ceylon; G. W. C. Parker, St. Bart.'s; G. F. S. Parker, Manchester; Lucy Parker, Royal Free; T. G. W. Parry, Guy's; V. Patrick, Manchester; W. F. Payne, Guy's; Dorothy E. Peake, London; G. M. Pennant, King's Coll.; A. Perkoff, London; S. W. Phoon, Guy's; P. J. J. Pienaar, St. Thomas's; E. B. Pollard, St. Bart.'s; Louisa M. Poynder, Charing Cross; J. O. Priestley, Middlesex; Winifred M. Proctor, Durham; Violet A. Quilley, Royal Free; V. I. Raman, London; R. H. T. Rea, St. Thomas's; T. S. Read, King's Coll.; E. J. Rees and W. E. Rees, St. Thomas's; H. D. C. Rice, King's Coll.; C. B. Rich, Charing Cross; F. Robinson, Manchester; R. E. Robinson, Guy's; Annie E. G. Rowlands, Univ. Coll.; M. Rubinstein, Guy's; E. Rudge, St. Bart.'s; F. R. Sandford, Middlesex; F. E. E. Schneider, Univ. Coll.; F. L. Scott, King's Coll.; A. de M. Severne, St. Thomas's; H. Sheard, Leeds; A Sherning, St. Thomas's; I. M. Sidley, St. Bart.'s; R. F. Smith, Guy's; J. A. Smorfitt, Leeds; I. Spiro, Univ. Coll.; Ethel L. A. Stamberg, Royal Free; A. W. Summersgill, Manchester; G. E. F. Sutton, King's Coll.; H. Taylor, London; M. Taylor, Guy's; A. K. Thomas, Univ. Coll.; O. O. S. Thomas, St. Mary's; W. G. Thwaites, St. Thomas's; R. W. H. Tincker, St. Bart.'s; R. J. Toleman, London; A. Tom, Guy's; G. M. Tothill, Charing Cross; C. H. C. Toussaint, Guy's; Henrietta Trend, Royal Free; V. C. Tughan, Univ. Coll.; Mary M. Turnbull, King's Coll.; Cicely N. Twining, Royal Free; B. D. Underwood, London; Hermione M. Usborne and Dorothy M. Vaux, Royal Free; I. R. Vermooten, Guy's; F. O. Walker, Middlesex; Constance Walters, Cardiff; J. L. Warner, Middlesex; H. O. Watkins-Pitchford, St. Thomas's; A. Watson, St. Mary's; M. A. Wiles, King's Coll.; E. R. Williams, Cardiff; H. H. Williams, Liverpool and Middlesex; R. C. Williams, Birmingham; W. M. Winder, St. Mary's; R. H. Yelf, King's Coll.; and G. C. Young, St. George's.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—Since the quarterly meeting of the College, reported in THE LANCET of Nov. 3rd, the Licence has been granted to Charles Henry Newman and Muriel Alice Stephens of King's College Hospital.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—The following candidates have passed the Final Dental Examination and have been granted the diploma L.D.S. R.C.S. Edin.:—

John B. Forgan, Bernard S. Reynolds, James G. Mackintosh, Pratap Singh Khosla, James W. Sykes, William R. Galloway, Robert G. Law, Douglas J. Kynoch, McGregor McLean, Nina Borrie Duncan, Joseph S. Sirey, John G. McClean, Lourens Wepener Ackermann, Charles E. Atkinson, Frank W. Walmsley, Alexander N. Wight, Robert Lauchlan, Archibald T. Donaldson, John Dewar, Kathleen M. Scott, Nico Hofmeyr Bartmann, Douglas R. Forster, John D. Riddell, Richard F. Pagnam, and Andrew R. Brown.

The following candidates passed in the subjects of Pathology, Medicine, and Surgery: John Murphy, Thomas Jamieson, John Campbell, and Orry Smedley Crowthers.

The following candidates passed in the subjects of Medicine and Surgery: Frederick A. Hunter and Edward N. Jamieson.

UNIVERSITY OF DUBLIN, SCHOOL OF PHYSIC, TRINITY COLLEGE.—At examinations held recently the following candidates were successful:—

FINAL MEDICAL EXAMINATION.

Part I., Materia Medica and Therapeutics; Jurisprudence and Hygiene; Pathology and Bacteriology.—John F. Wilde (passed on high marks), Thomas W. MacDowell, Thomas C. Foster, William J. A. M'Mahon, Mary C. Livingston, Charles F. D. M'Caldin, Gladys M. A. Lowry, William H. Coen, Philip Coleman, Richard T. Cronin, Mary Galvin, George A. Miller, James J. Cusack, Augusta M. Young, and William O. Warrington.

IN COMPLETION.

Gordon P. Bamford, Denis J. Cussen, John Cussen, Edward C. Dudgeon, Charles J. du Plessis, Robert W. Harte, Launcelot W. R. Haskins, John M. Johnston, Christopher Lord-Flood, Robert H. M'Keag, Kenneth F. Mackenzie, William H. Maguire, Henry M. Nevin, David N. Power, Frederick M. Purcell, John St. Clair, Israel Strasburg, François J. Swanepoel, and Carmichael Wilson.

DIPLOMA IN PUBLIC HEALTH.

Part I.—Frederick Stevenson, William B. E. M'Crea, George C. B. Robinson, and Richard Seale.

Part II.—Frederick Stevenson, William B. E. M'Crea, Patrick M. J. Bobbett, George C. B. Robinson, and Richard Seale.

UNIVERSITY OF PARIS.—An honorary degree in medicine is to be conferred upon Prof. Camillo Golgi, of Pavia, and Prof. W. W. Keen, of Philadelphia, in the amphitheatre of the Sorbonne on Nov. 24th. Sir J. J. Thomson will receive an honorary degree in science at the same time.

PAPWORTH VILLAGE SETTLEMENT.—A private view of a film illustrating the work of this settlement will be held at the Gaumont Co.'s Projection Theatre, Sherwood-street, Piccadilly Circus, London, W. 1, on Nov. 15th at 4 P.M.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL.—The new school of dental surgery will be opened on Nov. 12th, at 4.45 P.M., when the inaugural address will be given by Mr. F. Dyke Acland, chairman of the Dental Board, Lord Hambleden presiding.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL.—The fifth series of lectures given at this hospital on Thursdays, at 5 P.M., to practitioners and students is now in progress. On Nov. 8th Dr. C. H. Roberts gave the first lecture on Hæmorrhages in Early Pregnancy. Subsequent lectures will be announced in our Medical Diary.

GLASGOW UNIVERSITY CLUB, LONDON.—This club will dine at the Trocadero Restaurant, London, W., on Dec. 6th, at 7.30 P.M., Sir William Leishman, F.R.S., presiding. Any Glasgow University men not members of the club, who desire to attend, are requested to communicate with the hon. secretaries, 1, Harley-place, London, N.W. 1.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.—The past and present students' dinner will be held in the King's Hall, Armstrong College, Newcastle-on-Tyne, on Tuesday, Nov. 27th, at 7.30 P.M., Sir David Drummond presiding. Tickets at 10*s.* 6*d.* may be obtained from the Hon. Secretary, Re-union Dinner Committee, College of Medicine, Newcastle-on-Tyne.

SMALL-POX IN ENGLAND AND WALES.—During the week ended Oct. 27th, 22 cases of small-pox were notified in England and Wales, with the following distribution: Durham, 2 (Southwick-on-Wear); Gloucestershire, 7 (Gloucester 5, "including 2 cases notified as chicken-pox but rediagnosed as small-pox," East Dean R.D. 1, Gloucester R.D. 1); Northumberland, 1 (Tynemouth); Notts, 10 (Hucknall, 9, Kirkby-in-Ashfield, 1); Yorks North Riding, 1 (Middlesbrough); Yorks West Riding, 1 (Adwick-le-Street).

ROYAL SANITARY INSTITUTE.—A sessional meeting will be held on Nov. 17th, 1923, in the Council Chamber, Town Hall, Ipswich, when discussions will take place on Sewage Disposal, to be opened by Mr. E. J. Silcock, followed by Mr. H. C. H. Shenton and others; and on Tuberculosis in Milk to be opened by Dr. W. F. Corfield, followed by Dr. A. M. N. Pringle and others. The chair will be taken at 10.30 A.M. by Dr. Louis C. Parkes. At 2 P.M. visits will be paid to the public health office, sanatorium, isolation hospital, electricity station and destructor, new water works, new baths, and Messrs. Harris (Ipswich), Ltd., bacon factory.

A meeting will be held at the Institute, 90, Buckingham Palace-road, London, S.W., on Nov. 26th, when Miss Muriel A. Payne, hon. secretary, International School of Nursing and Child Welfare for Russia, will give an address on Sanitary Relief Work in Russia. The chair will be taken at 5 P.M. by Dr. Louis C. Parkes.

West Kent Medico-Chirurgical Society.—A meeting will be held in the board room of the Miller General Hospital, Greenwich, to-day, Friday, Nov. 9th, at 8.45 P.M. Dr. E. G. Annis, the President, will occupy the chair, and Dr. Hildred Carlill will read a paper on Tabes Dorsalis.

Royal Northern Hospital.—The Prince of Wales will open the new Casualty Department of the hospital (which is the War Memorial of the borough of Islington) on Nov. 27th. Contributions amounting to £12,000 have been received towards the cost of the department, which will be one of the best equipped in London, but a further £1000 are required to open the building free of debt.

St. John's Hospital for Diseases of the Skin.—In connexion with the recent developments at this hospital, and the formation of the London School of Dermatology, a dinner was given at the Trocadero Restaurant last month to Dr. James H. Stowers by his dermatological colleagues. Dr. Stowers was very largely responsible for carrying through the negotiations which have culminated in the present coöperative scheme. His colleagues have recognised the importance of this service, and their appreciation was suitably voiced at the complimentary dinner by Sir Malcolm Morris, who was in the chair, and by Dr. W. Griffith, senior physician to St. John's Hospital.

Medico-Psychological Association.—The next quarterly meeting of the Medico-Psychological Association of Great Britain and Ireland will take place on Nov. 22nd, at 11, Chandos-street, Cavendish-square, London, W., under the presidency of Lieut.-Colonel E. Goodall, at 2.45 P.M Prof. D. C. Winckler, of the Psychiatric-Neurologic Clinic, Utrecht, will deliver an address on Psychiatrical and Neurological Teaching at the Dutch Universities, especially at the University of Utrecht.

It is proposed to hold a dinner at the Langham Hotel, Portland-place, London, W., on Nov. 22nd, at 7 P.M. for 7.30, in honour of Prof. Winckler. Tickets, 10*s.* 6*d* each, should be procured as soon as possible from the hon. general sec., Dr. R. Worth, Springfield Mental Hospital, nr. Tooting, S.W. 17.

Fusion of Venereal Diseases Societies.—At a joint conference between the National Council for Combating Venereal Diseases and the Society for the Prevention of Venereal Disease, held at 1, Wimpole-street, London, W., on Oct. 30th, the following resolutions were adopted :—

1. That the ultimate fusion of the two societies is desirable.
2. Subject to the approval of their respective executives this conference resolves itself into a deputation to the Ministry of Health to urge that "the law should be altered so as to permit properly qualified chemists to sell ad hoc disinfectants, provided such disinfectants are sold in a form approved and with instructions for use approved by some competent authority."
3. That this conference recommends that the respective executives of the two societies should each appoint not more than five members to form a liaison committee between the two societies and to explore the possibility of fusion.

Scientific Novelties Exhibition.—The exhibition held at King's College during the Christmas holidays, 1922-23, aroused such interest, and was the means of raising so substantial a sum in aid of the hospitals of London, that it has been decided to repeat the experiment this year. The exhibition will be open from Dec. 29th to Jan. 9th (inclusive), between the hours of 2 and 9 P.M., and experiments and demonstrations will be going on continuously during this period, as on the last occasion. Short lectures with experimental or lantern illustrations will also be given, and promises of such lectures have already been received from Prof. Cheshire, Prof. Winifred Cullis, Prof. Eddington, Sir Richard Gregory, Prof. Morley Davies, Prof. Smithells, and others. The proceeds will be given to King Edward's Hospital Fund for London.

Tuberculosis Society.—An ordinary meeting of the Society will be held on Nov. 16th, at 8 P.M., at 1, Upper Montague-street, Russell-square, London, W. Dr. Evrot (Comité National de Défense Contre la Tuberculose) will read a paper on Tuberculosis in France, and the relationship of tuberculosis officers to local infirmaries will be discussed. On Dec. 14th Mr. R. Milne will discuss Operative Fixation for Caries of the Spine. On Jan. 18th, 1924, Dr. A. S. MacNalty will speak on Tuberculosis Work in England. On. Feb. 15th Dr. Clive Riviere will give a lecture on Artificial Pneumothorax. The meeting on March 21st will be devoted to considering the Tuberculosis Work of the Ministry of Pensions, Administrative and Clinical, when Dr. G. Basil Price and Dr. Alex. Sandison will read papers. On April 18th there will be a provincial meeting, and on May 16th a member of the National Tuberculosis Association of America will discuss Tuberculosis Work in America. On June 20th the annual meeting will be held. Meetings will be held at Margaret-street Hospital, Margaret-street, W., at 8 P.M., unless otherwise announced.

Liverpool Medical Institution: Biennial Dinner.—On Nov. 1st Sir Arthur Keith was entertained as the guest of the evening at a dinner attended by 150 members. Dr. Hill Abram presided. The health of the Liverpool Medical Institution was proposed in a spirit of delicate banter by Prof. Campagnac. He declared himself an admirer of the good old days, and trusted that the profession would maintain its reputation for urbanity, refinement, sage counsel, and good friendship. He reminded his hearers that unless they understood their patients as men they could do them little service as doctors. "The Guests" was proposed by Mr. F. C. Larkin in happy vein, and Sir Arthur Keith replied with a light touch and a sure instinct for the right word. He spoke of the law of relativity in relation to life and medicine, and he told of men he had known as not too brilliant students, now themselves teachers and impatient of the stupidity of those they had to teach forgetful of the passage of the years in which they had been gathering wisdom. He glanced at Bernard Shaw's picture of the span of human life lengthened out to 300 years or more and painted the misery of the young men who, he sometimes thought, would be better pleased with an age limit of, say, 35. The President of the Chester Medical Society also spoke.

Conference of Cremation Authorities.—Under the auspices of the Cremation Society of England, a conference was held on Oct. 25th at the Town Hall, Liverpool The conference was opened by the Lord Mayor of Liverpool (Mr. F. C. Wilson) and Dr. Herbert T. Herring occupied the chair. In his address Dr. Herring referred to the enormous advantages which the universal adoption of cremation would confer upon the community. Its progress had been slow, but it now looked as if we were on the threshold of great developments in this direction, requiring only the combined effort of all to make cremation the usual and accepted method of reverent disposal of the dead. With regard to propaganda, Dr. Herring recapitulated the proposals made at the conference held in 1922 ; these were briefly as follows Advocacy of the æsthetic side of cremation rather than of the indisputable sanitary advantages ; advertisement in the public press, and by propaganda literature ; removal of the fear of concealment of crime ; encouragement of the public to visit crematoria ; popular lectures ; and the obtaining of signatures to the form "requesting cremation at death." Many, if not all, of these suggestions had been acted upon during the last 12 months, to the advantage of the movement ; prominence had been given to the idea of the "Garden of Rest" for the undisturbed repose of ashes and incidentally for the solution of the cemetery problem. Improvements had been effected in buildings, and all jarring notes during the cremation ceremonial had been removed. With regard to press announcements and distribution of literature, the Cremation Society of England alone distributed by various means some 60,000 books and leaflets. When it was known that inspection was invited, 600 people had visited the Bradford crematorium in one day. The secretary of the Cremation Society reported a steady increase in the number of names registered, as well as in the number of persons who have effected prepayment for their ultimate cremation by joining the Society. Following Dr. Herring's address, a letter from the International Conference on Cremation, held at Gothenburg on August 30th and 31st and Sept. 1st, signed by Mr. J. Schlyter (hon. director, Swedish Cremation Union and Mr. F. Mencl (Cremation Society of Czecho-Slovakia was read, in which it was suggested that advantage should be taken of the exhibition to be held in London in 1924, to include therein a representative cremation exhibition, similar to those held at Maleno in 1914 and at Gothenburg this year ; and that the sixth World Conference for Cremation should take place in London in 1924. It was agreed that the latter conference should be of an international character if sufficient support could be obtained. A debate then took place in which speakers from London, Liverpool, Manchester, Birmingham, Hull, Bradford and South Wales took part. Among the suggestions made were the education of the younger generations through such organisations as the boy scouts and the girl guides, and the approaching of such social and educative bodies as the Rotary Clubs and the Workers' Educational Association together with requests to the medical faculty, the clergy and the Association of Undertakers for increasing coöperation with the cremation authorities. Medical support was acknowledged, and the undertakers, it was agreed, had refuted a charge of indifference on their own part. Prof. E. W. Hope medical officer of health for Liverpool, said that the advantages of cremation were emphasised when, as in Church-street Liverpool, thousands of bodies had to be removed for re-interment. The greater the pains which had been taken to preserve the bodies by metal coffins and bricked graves or vaults, the more revolting was found to be the condition of the remains when removal was necessary in the interests of the living.

ROYAL SOCIETY.—A Royal Medal has been awarded to Prof. C. J. Martin, F.R.S., for his researches on animal metabolism.

LONDON SCHOOL OF TROPICAL MEDICINE.—The annual dinner will be held on Wednesday, Nov. 21st (7.15 for 7.30 P.M.), at the Hotel Victoria, Northumberland-avenue. Sir Ion Hamilton Benn will preside.

ROYAL MANCHESTER CHILDREN'S HOSPITAL.—The board of the Manchester Children's Hospital has been notified from the Home Office of the King's command that the Children's Hospital shall henceforth be known as the Royal Manchester Children's Hospital.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—In addition to the courses previously announced for this month and now in progress—i.e., gynæcology, psychological medicine, and venereal disease—there will be a series of lecture-demonstrations on children's diseases at the Children's Clinic, Western General Dispensary, from Nov. 12th to Dec. 6th. The subjects dealt with will include gastro-intestinal, respiratory, genito-urinary, and skin affections in children. A special course in ophthalmology will be given at the Royal Westminster Ophthalmic Hospital from Nov. 19th to Dec. 15th, and apart from the clinical instruction each afternoon there will be special demonstrations in medical ophthalmology and methods of examination. During December there will be a refresher course in general medicine and surgery from the 3rd to the 15th at the Hampstead General Hospital, with which will be associated the Hospital for Epilepsy and Paralysis, the North-Western Fever Hospital, and Paddington Green Children's Hospital. The course will be a whole-time one and will include work in all departments. There will also be a course in neurology at the Hospital for Epilepsy and Paralysis, Maida Vale, of which further particulars will be announced later. Full particulars and copies of the syllabus of the foregoing courses will be forwarded on application to the Secretary to the Fellowship of Medicine, 1, Wimpole-street, London, W.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the Committee 44 cases were considered and £518 12*s*. voted to 38 applicants. The following is a summary of some of the cases relieved.

Daughter, aged 29, of L.R.C.P. & S. Irel. who practised in Liverpool and died in 1919. During the war the applicant was at the Bank of England as a temporary clerk. The temporary staff was dismissed last July and the applicant then came to London to get a post, but owing to being untrained she was unsuccessful. She now asks the Fund to help with training fees as she has only £3 left of her savings. The Committee made a small grant to render the applicant eligible for help from the R.M.B.F. Guild.

Widow, aged 59, of M.B. Aberd. who practised in Norwich and died in 1916. After the death of her husband she went to live with her mother, who had a pension, but she died in November last year. Applicant tried to earn by keeping poultry, but found that she was out of pocket. Her only income is the interest on £100 War Loan and £250 mortgage. She asks the Fund to help her with her rent, which amounts to £13. Voted £15.

Daughter, aged 65, of M.D. Aberd. who was a deputy inspector in the R.N. and died in 1904. Applicant has been living with her sister where they had their rooms free, but applicant developed mental trouble and the trustees of the home said she must find other accommodation. This necessitated her finding a lodging where she would have good attendance and also near her sister. This was secured a few doors away, and the one room and boxroom amounts to a rent of £1 per week. Her income is only £60 per annum. Voted £12 in 12 instalments.

Widow, aged 52, of L.R.C.P. & S. Edin. who practised in Wales and died in 1902. Applicant is a nurse, and has found it difficult to obtain work and has only received £90 in the last nine months. Her rent is £20, and she has to find £50 towards her daughter's board, who is a dental student. Applicant asks for a grant towards her daughter's expenses. The Committee made a small grant to render her eligible for help from the R.M.B.F. Guild.

Widow, aged 30, of L.R.C.P. & S. Irel. who practised in South London and died in August last. Owing to the sudden death of her husband and having two small children the applicant asked the Fund for assistance, and the Committee voted £15.

Widow, aged 35, of M.D. Glasg. who practised in North London and died in 1916. Since the death of her husband the applicant has managed to maintain herself and children, but she now asks the Fund to assist her in the education of her two children, aged 11 and 8 years. The Committee voted a small grant to enable her to receive assistance from the R.M.B.F. Guild, to whom the case was referred.

Daughter, aged 81, of M.R.C.S. who practised in Kent and died in 1868. Applicant was a mental nurse but is now too old to work. Her total income is £50 per annum and her rent amounts to 6*s*. 6*d*. per week. Relieved once, £26 in 12 instalments. The Committee again voted the same amount.

A donation of £2 was received anonymously from Correggio at the beginning of October, and the Treasurer desires to thank the donor and trusts that this acknowledgment will be duly noted. Subscriptions may be sent to the honorary treasurer, Sir Charters Symonds, K.B.E., M.S., at 11, Chandos-street, Cavendish-square, London, W. 1.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, Nov. 12th.

WAR: at 5 P.M.
Paper:
Major A. T. Frost, R.A.M.C.: The Present-day Trend of the Treatment of Gonorrhœa, with special reference to Cataphoretic Application of Colloid Silver, to be followed by a discussion opened by Colonel L. W. Harrison, R.A.M.C.

TROPICAL DISEASES AND PARASITOLOGY: at 8.30 P.M.
Presidential Address by Prof. Leonard S. Dudgeon.
Communications:
Dr. Ernest Caroll Faust (Peking Union Medical College): Some Biological and Practical Aspects of Schistosomiasis in China.
Miss G. Le Bas: On the Employment of Fasciola Hepatica as an Antigen for the Serum Diagnosis of Bilharziasis.

Tuesday, Nov. 13th.

THERAPEUTICS AND PHARMACOLOGY: at 4.30 P.M.
Presidential Address:
Prof. A. J. Clark: Commercial Influences in Therapeutics.

PSYCHIATRY: at 8.30 P.M.
Presidential Address:
Dr. T. B. Hyslop: Some Problems of the Future.

Wednesday, Nov. 14th.

SURGERY: SUBSECTION OF PROCTOLOGY: at 5.30 P.M.
Presidential Address:
Mr. Aslett Baldwin: The Causes of Intestinal Disease.

Thursday, Nov. 15th.

DERMATOLOGY: at 5 P.M. (Cases at 4.30 P.M.)
Cases:
Dr. H. W. Barber: (1) Tuberculides associated with Rheumatoid Arthritis; (2) Some cases of Light Sensitisation.
Mr. C. G. Brodie (introduced): Notes on a case of Sclerodermia treated by Polyglandular Extracts.
Other cases will be shown.

Friday, Nov. 16th.

ELECTRO-THERAPEUTICS: at 8.30 P.M.
Paper:
Prof. Leonard Hill: Physiological Effects of Light, to be followed by a discussion.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.
MONDAY, Nov. 12th.—8.30 P.M., Discussion on Constipation from the General Practitioners' Point of View. Introduced by Dr. H. Des Vœux.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.
THURSDAY, Nov. 15th.—7.45 P.M., Demonstration of Various Spirochætes. 8.15 P.M., Dr. John Gilks (of Nairobi): Yaws in Kenya Colony, illustrated by lantern slides.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

UNIVERSITY OF LONDON ADVANCED LECTURES IN SURGERY.
MONDAY, Nov. 12th.—(At Guy's Hospital Medical School.) 5.30 P.M., Prof. E. W. Hey Groves: The Treatment of Injuries of the Long Bones produced by Accident or Disease. Third Lecture.
TUESDAY.—5.30 P.M., Last Lecture.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.
MONDAY, Nov. 12th.—10 A.M., Mr. Maingot: Surgical Pathology. 12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Mr. Addison: Surgical Wards.
TUESDAY.—10.30 A.M., Dr. Paterson: Medical Wards. 12 noon, Dr. Burrell: Chest Cases. 2.30 P.M., Mr. Tyrrell Gray: Surgical Wards.
WEDNESDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 12.15 P.M., Dr. Burnford: Medical Pathology. 3 P.M., Dr. Pernet: Skin Dept.
THURSDAY.—11 A.M., Mr. Simson: Gynæcological Demonstration. 12 noon, Mr. Simmonds: Demonstration of Fractures. 3 P.M., Dr. Scott Pinchin: Medical Out-patients.
FRIDAY.—10 A.M., Dr. Drummond: Gynæcological Operations and Wards. 12 noon, Mr. Endean: Venereal Diseases. 2 P.M., Mr. Sinclair: Surgical Out-patients.
SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.
Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

ST. JOHN'S HOSPITAL, 49, Leicester-square, W.C.
TUESDAY, Nov. 13th.—5 P.M., Dr. A. M. H. Gray: Externally Produced Eruptions.
THURSDAY.—5 P.M., Dr. M. G. Hannay: Urticaria.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: October–November, 1923.

Clinical Lectures and Demonstrations.

Monday, Nov. 12th.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., Epilepsy: Dr. Aldren Turner.

Tuesday, Nov. 13th.—2 P.M., Out-patient Clinic: Dr. Grainger Stewart. 3.30 P.M., Disorders of Sensation and their Significance: Dr. Hinds Howell.

Thursday, Nov. 15th.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Spinal Cord Tumours: Dr. Grainger Stewart.

Friday, Nov. 16th.—2 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Surgery of Cerebral Tumours: Mr. Sargent.

Course of Lectures and Demonstrations on Neuro-Pathology.

Monday, Nov. 12th.—12 noon, Pathology of the Neuron, II.: Dr. J. Godwin Greenfield.

A Course of Lectures on the Anatomy and Physiology of the Nervous System commenced on Oct. 16th.

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M., or at such other times as may be announced.

The fee for the Course, including Pathology, is £5 5*s*. The fee for the Anatomy and Physiology Lectures is £3 3*s*. If taken in conjunction with the Clinical and Pathological Courses an inclusive fee of £7 7*s*. will be charged. Any part of the Course may be taken separately. Special arrangements will be made for those unable to take the whole Course. Fees should be paid to the Secretary of the Hospital at the Office on entering for the Course.

C. M. Hinds Howell, Dean of Medical School.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

Thursday, Nov. 15th.—4 P.M., Dr. Hutchison: Wasting.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.

Thursday, Nov. 15th.—5 P.M., Mr. J. B. Banister: Forceps in Obstetric Practice.

THE PEOPLE'S LEAGUE OF HEALTH, 12, Stratford-place, Oxford-street, W.

Eight Lectures on the Mind and What We Ought to Know About It, at Hamilton House, Mabledon-place, W.C.

Wednesday, Nov. 14th.—6 P.M., Third Lecture, Dr. R. G. Rows: Association of Ideas, Recognition, and Memory.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.

Wednesday, Nov. 14th.—4 P.M., Mr. W. B. Smith: The Extravagance of a Smoke-polluted Atmosphere.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE CLINIC.

Tuesday, Nov. 13th.—4.15 P.M., Dr. D. E. Core: Differential Diagnosis of Paralysis Agitans.

Friday.—4.15 P.M., Dr. T. H. Oliver: Physiology and Pathology of Diabetes Mellitus.

SALFORD ROYAL HOSPITAL.

(Special Course on Surgical Tuberculosis.)

Thursday, Nov. 15th.—4.30 P.M., Mr. J. B. Macalpine: Renal Tuberculosis.

LIVERPOOL UNIVERSITY POST-GRADUATE LECTURES.

(At 3.30 P.M. each day.)

Monday, Nov. 12th.—(At the Hospital for Women.) Dr. Willett: Uterine Displacements.

Tuesday.—(At the Maternity Hospital.) Prof. Blair Bell: Difficulties and Dangers of the Typical Funnel-shaped Pelvis and Uterine Inertia.

Wednesday.—(At the St. Paul's Eye Hospital.) Mr. Thomas Stevenson and Mr. Gorst: Clinical Cases.

Thursday.—(At the St. George's Skin Hospital.) Dr. Barendt: Skin Cases.

Friday.—(At the Eye and Ear Infirmary.) Mr. H. E. Jones: The Differential Diagnosis of Inflammatory Affections of the Eye.

UNIVERSITY OF BRISTOL POST-GRADUATE DEMONSTRATIONS.

Wednesday, Nov. 14th.—(At Swindon), Dr. J. A. Nixon: Diabetes and Modern Methods of Treatment.

Appointments.

Cave, P. N., M.D., B.Ch. Oxf., has been appointed Medical Officer of Health, West Kent United Districts.

Handford, H., M.D. Edin., Consulting Medical Officer of Health for the County of Nottinghamshire.

Howell, B. W., F.R.C.S. Eng., Visiting Surgeon to the Ministry of Pensions Hospital, Shepherd's Bush.

Miller, J. E. D., M.B., B.S., and Griffiths, J. V., M.R.C.S., L.R.C.P., House Surgeons to the Royal Infirmary, Sunderland.

Newell, R. L., M.D. Manch., F.R.C.S. Eng., Honorary Surgeon for Children to the Manchester Northern Hospital.

Pearson, E., F.R.C.S. Edin., Medical Referee under the Workmen's Compensation Act for County Court Circuit No. 57, Barnstaple, Bideford, South Molton, and Torrington County Courts.

Smellie, J. M., M.D. Edin., M.R.C.P., Pathologist at the Queen's Hospital, Birmingham.

Vacancies.

For further information refer to the advertisement columns.

Barnsley, Beckett Hospital and Dispensary.—Sen. and Jun. H.S.'s. £300 and £200 respectively.

Bath, Royal United Hospital.—Hon. Ophth. S.

Belfast, Joint Nursing and Midwives Council.—Examiners of Midwives.

Benenden, Kent, National Sanatorium.—Res. Asst. M.O. £275.

Birkenhead Borough Hospital.—Sen. and Jun. H.S.'s. £200 and £150 respectively.

Birmingham and Midland Eye Hospital, Church-street.—Surg. Reg.

Birmingham, Queen's Hospital.—Med. Reg. £100.

Bristol General Hospital.—Hon. Asst. S.

Bristol Royal Infirmary.—Hon. Asst. Dental S.

British Honduras.—Asst. M.O. $2430.

Bury County Borough.—Asst. M.O.H., &c. £600.

Cambridge, Addenbrooke's Hospital.—H.P. £130.

Cambridge University.—Lecturer in Biochemistry. £350.

Dreadnought Hospital, Greenwich.—H.S. £150.

Eastbourne, Princess Alice Memorial Hospital.—Hon. Ophth. S.

Edinburgh Royal Infirmary.—Supt. £700.

Elizabeth Garrett Anderson Hospital, Euston-road, N.W.—H.P., Obstet. Asst., and Two H.S.'s. Each £50.

Epsom, The Manor.—Jun. Asst. M.O. £300.

Evelina Hospital for Children, Southwark, S.E.—H.P. £160.

Hospital for Sick Children, Great Ormond-street, W.C.—H.S. and H.P. £50.

Indian Medical Service.—Vacancies.

Italian Hospital, Queen-square, W.C.—Hon. Ophth. S.

Leeds Public Dispensary.—Sen. Res. M.O. £200.

London County Mental Hospital Service.—Seventh Asst. M.O. £432.

Londonderry County and County Borough Infirmary.—S.

Maidstone, Kent County Mental Hospital.—Asst. M.O. £350.

Manchester and Salford Hospital for Skin Diseases.—H.S. £100.

Manchester City.—M.O. £620 19*s*. 9*d*.

Manchester, St. Mary's Hospitals for Women and Children.—Two H.S.'s. Each £50.

Nottinghamshire County.—M.O.H. £100.

Pontefract, General Infirmary and Dispensary.—Res. Surg. O. £400.

Poplar Hospital for Accidents, East India Dock-road, E.—Sen. Res. O. £275.

Prison Medical Service.—M.O.'s. £432.

Queen Charlotte's Lying-in Hospital, Marylebone-road, N.W.—Two Asst. Res. M.O.'s. £80.

Queen Mary's Hospital for the East End, Stratford, E.—Anæsthetist. 50 guineas.

Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—Asst. Cas. H.S. £100.

St. Albans City.—M.O.H., &c. £900.

St. Peter's Hospital, Henrietta-street, W.C.—Asst. S.

Salisbury Municipality, Rhodesia.—M.O.H. £600.

Sheffield, Jessop Hospital for Women.—Sen. Res. O. £250. Also Two H.S.'s. Each £100.

Wandle Valley Isolation Hospital, Beddington Corner, Mitcham Junction.—R.M.O. £400.

West London Hospital, Hammersmith-road, W.—Hon. Asst. S. to Throat, Nose, and Ear Dept.

Willesden General Hospital, Harlesden-road, N.W.—H.S. £100.

The Chief Inspector of Factories, Home Office, London, S.W., announces vacant appointments at South Petherton (Somerset) and Shifnal (Salop).

Births, Marriages, and Deaths.

BIRTHS.

Barclay.—On Nov. 5th, at 2, Greenhead-road, Huddersfield, the wife of Wm. Barclay, M.B., F.R.C.S. Edin., of a daughter.

Cook.—On Oct. 30th, at Lyme Regis, the wife of P. Nield Cook, M.B., of a daughter.

Feldman.—On Nov. 1st, at Arkwright-road, Fitzjohn's-avenue, N.W., the wife of Dr. Israel Feldman, of a son.

Haslett.—On Oct. 30th, the wife of Dr. W. Handfield Haslett, J.P., Halliford House, Shepperton, of a daughter.

MARRIAGES.

Peebles—Marshall.—On Oct. 30th, 1923, at the Parish Church. Cheltenham, by Rev. Dr. J. D. Mullins, assisted by Canon H. A. Wilson, Rector and Rural Dean of Cheltenham, and Rev. C. H. Lancaster, Vicar of St. John's, Cheltenham. David James, elder son of the late T. S. Peebles, Esq., and Mrs. Peebles, of Dundee, to Marjorie Grace, elder daughter of Mr. and Mrs. Charles Marshall, of Carlton Lawn. Cheltenham.

DEATHS.

Edwards.—On August 15th, at the Manchester Royal Infirmary. after operation, John Edwards, M.R.C.S. Eng., L.R.C.P. Edin. & L.M., of Withington-road, Whalley Range, Manchester, aged 69 years. Late Senior Medical Officer, H.M. Prison Service.

Hall.—On Oct. 27th, at Ulidia, Bexhill, Geoffry Craythorn Hall, Colonel, I.M.S. (retired), aged 75 years.

Latham.—On Oct. 29th, at York-crescent, Clifton, Bristol, Peter Wallwork Latham, M.D., F.R.C.P., aged 91 years.

Scott.—On Nov. 2nd, at High-street, Musselburgh, Thomas Rennie Scott, M.D., aged 70.

Smith.—On Nov. 3rd, at a nursing home in Blackheath, S.E., Henry Lionel Smith, J.P., M.R.C.P.Irel.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

RADIOSCOPY AND RADIOTHERAPY.*

BY SIR HUMPHRY ROLLESTON, K.C.B., M.D. CAMB.,

PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AT a time when financial stress is forcing many hospitals to close some of their wards it speaks well for the generosity of the Weymouth public and the energy of this hospital's authorities that to-day sees the addition of a wing for an expanded X ray department. This important improvement is appropriately dedicated to the memory of Dr. James Miller, who for 15 years devotedly served the poor of this hospital, and died within its walls on Nov. 9th, 1918, almost exactly five years ago, from lung complications of influenza. Like many unselfish men of his profession he neglected himself to care for others and went about his work with a temperature of 104° F., which he certainly would not have allowed any one else to do. Always willing to help in any capacity, generous and sympathetic, he was the friend of the poor, and did not let his light shine prominently before men; a genuine sportsman, he played the game for his side, never for his own hand. Often such a life has its only memorial in the gratitude, genuine though necessarily transient, of the poor; but his relations, colleagues, friends, and patients have rightly determined to perpetuate the good work he had silently carried out by erecting and equipping a new X ray department which bears the name of their beloved physician—The James Miller Memorial Wing. Among these benefactors of the hospital are his mother, Mrs. Miller, who gave £1000, members of the hospital staff who collected £700, Mrs. Sanderson-Wells and Mrs. C. Barrett, who got up two fêtes realising £1200 and £2000 for this pious object.

The Beginnings of X Ray Work.

Prof. W. K. v. Röntgen, of Würzburg, discovered X rays when working with a Crookes's high vacuum tube electrically excited, in November, 1895; and it was therefore a great Englishman, Sir William Crookes (1832–1919), whose work rendered this discovery possible. Röntgen died at Münich on Feb. 10th last in his seventy-eighth year, and thus had the satisfaction of seeing the enormous advances that his observation has rendered possible, not only in pure science but in its practical application, especially in the art of healing. Those who were in practice before radiology became the handmaiden of medicine and surgery know what a revolution has taken place in our means of accurately detecting disease. This is shown, perhaps as well as any detailed review would do, by the fact that an action for professional negligence has been brought against a medical man on the ground that he did not employ X rays in a case of possible fracture of a bone. Unlike many great advances in medicine, notably Lister's antiseptic method, the use of X rays was at once taken up most enthusiastically and, though its professional applications took some years to develop, on account of many technical difficulties, it was never neglected or opposed. In fact, within a week of the announcement of the discovery, Cox, in far-off Montreal, localised a bullet which for seven years had caused trouble in a patient's leg and so led to its extraction on the following day. First employed for the detection of fractures, foreign bodies, and calculi, X rays were in the same year (1896) applied by J. Macintyre, of Glasgow, to the diagnosis of intrathoracic disease, such as aneurysm; about ten years later pyelography came into vogue. That advances are constantly being made may be shown by a few examples; the introduction of gas into the abdominal, cranial, or even other cavities before an X ray picture is taken is now employed to define more clearly the position of a tumour, and Dr. R. W. A. Salmond [1] has shown how valuable the introduction of air into the pericardium—a previously unexploited region by this method—may possibly be in the detection of unusual and otherwise unrecognisable lesions; Prof. Jacobaeus's thoracoscopy with division of pleuritic adhesions under the X rays opens new possibilities in connexion with the treatment of pulmonary tuberculosis by artificial pneumothorax; Sicard's method of localising the level and extent of spinal fractures, adhesions, or tumours obstructing the intrathecal space by means of injection of lipiodol (a non-toxic solution of iodine in poppy-seed oil) before the spine is X rayed, now employed by him in 150 cases,[2] is a most promising aid to diagnosis; Mr. P. Sargent [3] was the first to report its use in this country; and Sicard's pupils, Jacques Forrestier and L. Leroux,[4] have applied it to the detection of pulmonary lesions such as bronchiectasis. The demonstration of gall-stones has been followed by that of other pathological changes in the gall-bladder; and the discovery, by Prof. Gôsta Forsell, of Stockholm, that the mucous membrane of the gastro-intestinal tract undergoes active movements, apart from the coarser contractions of the muscular coat, and thereby controls the distribution and regulation of the contents, has physiological and pathological bearings as yet not recognised. As regards diagnosis, X rays have provided an additional sense or new eye, and their extension of the field of vision is comparable with the advance made when microscopic lenses and telescopes were first introduced. In the 28 years since X rays were discovered the mental attitude of clinical workers has gradually undergone a change, the magnitude of which is only realised when a medical man finds himself in some place where X rays are not available for help in a case of doubtful diagnosis.

X Ray Treatment.

X rays are not so widely employed or so well established in treatment as in diagnosis and, as has already been pointed out, it is mainly in regard to the latter that they have changed our outlook on medicine. In some skin diseases and superficial tumours their beneficial influence has been proved beyond question, and the autolytic effect of irradiations has been utilised in uterine fibromyomas, prostatic hypertrophy, erythræmia, exophthalmic goitre, metrorrhagia, lymphadenomatous and other enlargements of glands, and chronic tonsillitis, and good results in other affections may confidently be anticipated. But remedies powerful for good are not without risk when employed in large doses, and the dangers attaching to X rays are now fully recognised. Those most constantly in contact with irradiations are naturally most prone to suffer, and many pioneers of radiology, before the risks were fully realised, paid dearly for their devotion. It has been estimated that a hundred radiologists have died from X ray carcinoma of the skin; and that aplastic anæmia, chronic ill-health, and sterility may be produced in radiologists is too well known. It is therefore important that the recommendations of the X ray and Radium Protection Committee should be acted upon, and that all new X ray departments should be inspected from this point of view by the National Physical Laboratory, Teddington.

The chronic ill-effects of X rays and radium are naturally almost only seen in X ray workers, but after long exposures, especially the intensive exposures for hours originating from Erlangen for carcinoma, patients may be extremely ill with acute constitutional symptoms and even die; this is, fortunately, a rare accident, and as our knowledge increases precautions will render it even more so. This form of treatment is still on its trial, and should be exhaustively tested at large X ray departments under the supervision of whole-time radiologists before its adoption is accepted as a routine therapeutic method of all hospitals. In some cases rapid spread of malignant disease supervenes after radiation and thus recalls the increase in lymphadenoma sometimes noticed after surgical removal of some of the affected glands. This may be independent of radiation or operative interference, but the question whether radiation, especially in small doses short of lethal action, stimulates the growth of cancer cells has been much discussed. In a review of this complex pathological question Ewing [5] concludes that the danger of stimulating the growth of tumours by the present methods of radiotherapy is extremely remote, and that the view that inadequate radiotherapy can endow the cells with increased vitality is quite unreasonable.

Important as a thoroughly complete and up-to-date equipment is, the first essential is that there should be a competent radiologist in charge of the department, and the Weymouth and District Hospital is most fortunate in having the services of Dr. Rodier Heath, who for 15 years has been the pioneer in this town, which thus provides an invaluable centre for radiological work.

A NEW SPECIES OF GERM.

Sheffield University has produced a new species of vibrio—an entirely non-pathogenic commensal organism. This germ takes the form of a little magazine, the *Vibrio*, grown on the culture medium of the University Medical Society. The journal is edited by a student committee, and the editors aim at creating an official organ "in which full reports of papers read before the society can be published, and in which much of the original work done in the Faculty of

---

* Remarks made at the Opening Ceremony of the James Miller X Ray Wing of the Weymouth and District Hospital, Nov. 3rd, 1923.

[4] Forrestier, J., et Leroux, L.: Jour. de radiol. et d'électrol., 1923, vii., 355.

[5] Ewing, James: Mutter Lecture—An Analysis of Radiotherapy in Cancer, Trans. Coll. Phys. of Philadelphia, 1922, 3rd ser., xliv., 203. Dr. R. Knox, who kindly drew my attention to this article, has also discussed this problem in a paper which will appear in the American Archives of Röntgenology for next January.

Medicine can be recorded." "Also," they add, "there must be many abnormal cases met with by students in hospital practice, cases which are worthy of record and which give scope for the explanation of students' difficulties ; we hope that in future students will submit such cases for publication." If that hope is realised, the journal will be of great service to those students who are really interested in their work. The preparation of a case for publication (whether it appears in print or not), necessitating as it does a concise exposition of essential facts and the crystallisation of ideas, promotes clearness of thought and develops the writer's power to grasp the main issue. This is a training which the preparation of case reports for examination purposes does not give, for many students cannot disabuse themselves of the idea that examiners are impressed by flowery language and adventitious "padding"—the more pages of manuscript filled, the higher the marks. An editorial blue pencil, wisely wielded, is the best corrective for such tendencies.

The aims of the journal are rightly ambitious ; they do not stop at recording original work done in the Faculty—original humour is also called for. We quote a promising sample, two stanzas of a "romance neurologique," entitled "Le Signe de Babinski" :—

Babinski turned his toes up
When stroked beneath the sole,
The doctors in attendance
Remarked, "Mais ! ça c'est drôle !"
It puzzled them immensely,
They'd always learned, and taught,
That people turned their toes down
When tickled. So they ought !

* * *

Babinski turned his toes up,
As all of us now know,
Because his upper neurones
Had lost control below.
The only normal people
Who do the same as he,
Are tiny little "babbies,"
Until they're two or three.

The journal starts on its career appropriately with an interesting article on the history of the Sheffield Medical School by Prof. Arthur J. Hall, and there is a page of really helpful advice to the student who is about to begin his clinical work in the infirmary.

PUBLIC HEALTH IN SIERRA LEONE.

A REPORT on this Colony and Protectorate for the year 1922, signed by Mr. W. B. Stanley, Acting Colonial Secretary, has been presented to Parliament. It states that the number of European and American residents during 1922 was 1202, of whom 209 were officials, 292 military, and 701 non-officials. The population of the Colony and Protectorate, taken together, increased from 1,403,132 in 1911 to 1,541,311 in 1921, or approximately 9·8 per cent. The deaths of Europeans from climatic and non-climatic causes in 1922 numbered 13. The birth-rate in Freetown (the capital) was 16·9 and the death-rate 26·3 per 1000, the corresponding figures for the rest of the colony being 20·2 and 21·2 per 1000. According to the 1921 census the males exceeded the females by 28·5 per cent. in Freetown, and 24·3 per cent. in the rest of the colony. Owing to the non-registration of many births the available birth-rate is undoubtedly much below the actual. The preponderance of females in the Protectorate is again noticeable, the figures being 599,199 women and 421,173 men, but these figures, it is pointed out, are based on a very rough and ready calculation drawn from a small representative area in each district. The Colonial Hospital was completely destroyed by fire early in 1920, and, pending reconstruction, temporary accommodation had to be arranged. A portion of the new hospital was completed and opened in 1922. This new hospital includes three more blocks for Africans and one for Europeans, besides quarters for the resident surgeon and nursing sisters. Patients admitted during the year numbered 1269, and there were 120 deaths ; 89 operations were performed ; 10,573 out-patients were treated at the Colonial Hospital, 2282 at the Cline Town Dispensary, and 3235 at the Kissy Dispensary. At the Leper Asylum there were two patients at the beginning of the year ; there were three admissions and one death. One case of small-pox and 37 cases of chicken-pox were admitted to the Infectious Diseases Hospital, of which one chicken-pox case died from senility. To the Nursing Home there were 126 admissions, 37 being Government officials ; 55 were cases of malaria and four of blackwater fever ; one official and six non-officials died. The climate is tropical, with a heavy rainfall and high atmospheric humidity during the greater part of the year. There is a single rainy season lasting roughly from May to the end of October. This constitutes the period of the south-west monsoon ; it is preceded and followed by a period of thunderstorms known as tornadoes. July, August, and September are the months of heaviest rainfall. In December and January Sierra Leone comes into the region of the north-east trades, and the resultant wind known as the "harmattan," blows from N.N.E. ; it is an exceedingly dry wind, and is accompanied by a thick haze probably composed of minute particles of dust. During this period there are cool nights and hot days. The lowest mean temperatures are usually recorded in the months of July and August. There are facilities for playing cricket football, tennis, and golf, and any European who wishes to play can get opportunities of doing so. The country is hilly, and cycling is in consequence laborious, and horses do not thrive, but for some distance out from Freetown the roads are good enough for motor-cars and motor-cycles to be used. The town enjoys a splendid pipe-borne water-supply the catchment area being situated in the mountains, where there is a large reservation of land.

A POPULAR GUIDE TO TRAVEL.

WE have received the first fortnightly part of "The Outline of the World To-day," edited by Sir Harry Johnston and Dr. Haden Guest (George Newnes, Ltd., 13 Southampton-street, London, W.C. 2, 1*s.* 2*d.*). The Outline, which is to be completed in about 24 parts, aims at giving an impression of the life and attractions of other lands. "We never use our eyes until we are on foreign soil," writes Mr. E. V. Lucas, and the editors of the Outline realise that it is not possible for the majority of people who visit a new country to discover everything for themselves. The Outline is written by experts in travel, and is not so much a guide-book as "a philosopher and friend, ready to conduct readers over the globe withou wearying them with cumbersome details." The first par deals with France as a whole, the land and the people following on with a more detailed study of Normandy and Brittany, the form and manner of government, and a description of selected spots of special beauty and interest. Maps are provided which will render the work when complete a reference atlas of the world. The Outline appear opportunely when facilities for travel are slowly becoming more normal, while a healthy desire to see and observ habits and manners other than our own is growing up all around.

SUPERINTENDENT NEEDED FOR A CHILDREN'S PREVENTIVE HOME IN AUSTRIA.

AN advertisement appears this week in our columns fo a resident lady superintendent with a good knowledge of the German language, to take charge of a British home fo Austrian children. Schloss Grafenegg, near Liezen, where the home is situated, formerly the country seat of Baron Dumba of Vienna, lies at an altitude of 2200 ft. on a wooded slope overlooking the valley of the Enns in Upper Styria. Owing to currency difficulties this home was on the point of being closed when it was taken over by the British Home fo Austrian Children, Ltd., an association formed for the purpose. Prolonged malnutrition has seriously undermined the natural vitality of many children in Austria and the menace of tuberculosis is serious. Should a child on the first signs of disease be removed to healthy environment and properly fed under medical supervision, a definite cure follows almost as a matter of course, and the home is to be run on the lines of a preventorium rather than as a sanatorium proper. Parents are invited to contribute as much as they can afford and it is intended to make the home self-supporting from the development of the farm as a pedigree stock centre. The qualifications required for the superintendent are good organising ability, knowledge of nursing, and some institutional experience, as well as a working knowledge of the language. Preference will be given to some one who has already worked or resided in the country.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg.-Comdr. F. G. Wilson is placed on the ret. list.
Surg.-Lt. B. S. Collings to be Surg. Lt.-Comdr.
Surg.-Lt. N. A. H. Barlow to be Surg. Lt.-Comdr.

ROYAL ARMY MEDICAL CORPS.

Maj. A. C. Vidal is placed on the half-pay list on account of ill-health.

ROYAL AIR FORCE.

W. J. Hutchinson is granted a short service commission as a Flying Officer.

After the memorial service on Armistice Day, the Assistant Director of Medical Services (London District), and a detachment of the Royal Army Medical Corps, will deposit a wreath on the Royal Army Medical Corps war memorial tablet in Westminster Abbey.

An Address
ON
COMMERCIAL INFLUENCES IN THERAPEUTICS.

Delivered before the Section of Therapeutics of the Royal Society of Medicine

BY ALFRED J. CLARK, *M.C.*, M.D. CAMB.,
F.R.C.P. LOND., D.P.H.,
PROFESSOR OF PHARMACOLOGY, UNIVERSITY OF LONDON;
PRESIDENT OF THE SECTION OF THERAPEUTICS.

CERTAIN work done during the past few years in examining widely advertised proprietary medicines impressed upon me the light-hearted manner in which some firms made sweeping therapeutic claims for their products, claims in support of which they had little or no direct evidence. In addition I found that when evidence was laboriously collected which indicated that these claims were erroneous, this usually made no difference whatever in the advertised statements. I was therefore naturally led to inquire as to what safeguards existed in England to ensure that the claims made in advertisements of drugs were at least not demonstrably false. I found, as a matter of fact, that no such safeguards existed. Reputable firms, out of regard for their good names, are, of course, careful as to what claims they make in advertisements, but beyond this the public has no protection. In my opinion this state of things is extremely prejudicial to the progress of therapeutics, and it is highly desirable that the medical profession should devise some sort of organisation for its own protection in this regard.

The quack is, of course, as old, or older, than the medical profession, but the exploitation of therapeutics by large commercial concerns was a development of the latter half of the nineteenth century mainly due to the rise of modern methods of large-scale advertisement. A company with extensive capital can employ more skilled assistance in conducting propaganda, and hence there is a general tendency for the cruder forms of gaining the public ear to disappear and to be replaced by much more refined methods.

The capitalisation of the drug industry has brought many very important benefits to medicine, for it has rendered possible the production of drugs of uniform quality, and it also has been of great help in the organised search for new remedies, yet it has introduced new evils.

There is no need to remind you that the trade in secret or quack remedies is an unmixed evil, but it is important to remember how large and powerful is the quack medicine trade. It was recently estimated that the capital employed in America in making secret remedies was larger than that employed in the legitimate drug trade. In England it was estimated that in 1913 more than £4,000,000 was spent in such remedies, and that the trade spent £2,000,000 in advertising. I mention these facts as evidence that very powerful and extensive commercial interests are engaged, and as I shall show later, there is no guarantee that this trade may not turn its attention to the medical profession if it conceives that exploitation of the medical profession will yield quicker profits than exploitation of the general public. At present the medical profession has practically no organisation available for its defence against such a move.

PROFESSION AND PUBLIC ALIKE UNPROTECTED BY LAW.

It is important to note that the law affords no protection whatever to the public or to the medical profession against any form of exploitation by proprietary medicine vendors, as long as these avoid the laws relating to obscenity. The law on the subject was summarised in the report of the Select Committee on Patent Medicines in 1914[1] as follows:—

> 22. The situation therefore as regards the sale and advertisement of patent and proprietary medicines and articles may be summarised in one sentence as follows. For all practical purposes British law is powerless to prevent any person from procuring any drug or making any mixture, whether potent or without any therapeutical activity whatever (so long as it does not contain a scheduled poison), advertising it in any decent terms as a cure for any disease or ailment, recommending it by bogus testimonials and the invented opinions and facsimile signatures of fictitious physicians, and selling it under any name he chooses, on the payment of a small stamp duty, for any price he can persuade a credulous public to pay.

The same Committee also came to these additional conclusions:—

> 55. (7) That the existing law is chaotic and has proved inoperative, and that successful prosecution for fraud in the advertisement and sale of secret remedies is fraught with the gravest difficulty, although the public prosecutor has perhaps not sufficiently tested the powers of the existing law in respect to such cases. (8) That consequently the traffic in secret remedies, except as regards scheduled poisons and the grosser forms of improprietary, is practically uncontrolled in this country.

The objection will at once be raised that these paragraphs refer to the obvious nostrums advertised in the lay press, nostrums which the medical profession has consistently denounced, and which really are of little concern to medical men. Unfortunately, it is impossible to make any easy definition which will divide such blatant frauds from proprietary medicines of highest therapeutic value. These extremes are so utterly dissimilar that it is hard to believe there is any relation between them, yet every possible intermediate grade exists, and it is a matter of utmost difficulty to establish any formula to determine which proprietary articles should be recognised by the medical profession and which should be condemned. There is, in fact, no definite line that can be clearly drawn between quack medicines and reputable proprietary articles.

There are, of course, certain classes of articles that the medical profession can condemn at once. Secret remedies require no discussion, for it is contrary to every professional tradition for a doctor to prescribe a remedy of whose composition he is ignorant. The advertisement of a secret remedy is, however, merely an indication of a lack of ingenuity and imagination on the part of the manufacturer. Nothing is simpler than to give a formula, and to claim either that one of the ingredients is obtainable only by the manufacturer, or that the value of the medicine depends upon the exquisite skill with which the ingredients are prepared and compounded.

THE ASTUTENESS OF THE ADVERTISER.

The rule that articles are to be advertised to the medical profession only is also absolutely worthless as a guarantee against fraud. Advertising to the public direct is expensive, whilst advertising to or even circularising the medical profession is relatively cheap. Hence it may pay better for a firm to confine itself to the medical profession. The same form of advertisement will not, of course, appeal equally to the lay mind and the medical man, but a skilled advertiser can exploit the latter. This danger became acute some years ago in America. I quote some remarks by Dr. G. H. Simmons, Editor of the *Journal of the American Medical Association.*[3]

> It has become a recognised fact in the patent medicine field that the easiest and cheapest way of reaching the public is through the doctor. Let me quote a paragraph that appeared in *Printers' Ink*, an advertising journal (about 1903). The words are those of a patent medicine man, and they are not directed to the medical profession. "But the patent medicine of the future is one that will be advertised only to doctors. Some of the most profitable remedies of the present time are of this class. They are called proprietary remedies. The general public never hears of them through the daily press. All their publicity is secured through the medical press, by means of the manufacturers' literature, sometimes gotten out in the form of a medical journal, and through samples to doctors. . . .

The original bottle is given to the patient; he sees that the remedy does him good, and when he feels a trifle run down again he goes to a drug store and buys another bottle, not troubling the doctor. He meets a friend on the street who is not looking well. 'I know exactly how you feel,' he says. 'Now just go and buy a bottle of . . . Best thing in the world. My doctor prescribed it for me, so it isn't a patent medicine.' In this way the names of remedies advertised only to physicians get abroad to the general public. The proprietary medicine of the future though will be advertised through these channels. The medical papers will reap the harvest, and the physician himself, always so loud in the denunciation of patent medicines, will be the most important medium of advertising at the command of the proprietary manufacturer."

Dr. Simmons concludes: "Have you ever seen an arraignment of this evil by its enemies which equals this cynical statement by its friends?" This quotation is, I think, sufficient to show that there are no simple rules by which the medical profession can protect itself against exploitation.

There are, as I have said, a vast range of proprietary medicines varying from valuable scientific preparations, such as the best brands of organic arsenical preparations down to the lowest form of quack frauds. The law is absolutely impotent, and medical men have got to make up their minds what they are prepared to recognise and what to reject. Huge commercial interests are involved, for it must be recognised that the more nearly a preparation approaches a fraud the more likely it is to reap a rich immediate harvest. Obviously an unscrupulous manufacturer will consider what types of chronic diseases are particularly refractory to treatment, and choose in preference those which are painful and afflict well-to-do patients. Such diseases are, of course, the despair of the general practitioner, and he will always be ready to try anything new that can possibly be of benefit. In preparing the remedy the manufacturer will probably select some new scientific discovery which is a novelty, and whose powers are still undefined. It is a great advantage, of course, if the substance is such that there is no easy method of testing its purity or activity. Any nostrum can obtain support from some medical man or another, if not in England at any rate on the Continent, and then the rest is easy, a commercial interest is there ready to boom the preparation; and it is not the business of anybody to check the statements made. Obviously the general practitioner who is not an analytical chemist, nor an experimental pharmacologist, nor a secret inquiry agency, has no means of testing the inherent probability of a new remedy. On the other hand, the exploiters of a new remedy have the power of money behind them to promote the sales and profits.

As regards the attitude of medical men to doubtful proprietary remedies, the following extracts from the Select Committee on Patent Medicines are of interest:

> 29. With regard to advertisements in the medical press, we consider that adequate censorship has not in all cases been exercised, as, indeed, was admitted by Dr. Cox, the representative of the British Medical Association, and instances to this effect will be found in the evidence received.
>
> 47. We have learned, however, to our great surprise, that persons of influential social positions and small means will sell the use of their names to advertise secret remedies; that large sums of money are expended in canvassing medical men; that many medical men give testimonials (with the use of their medical qualifications, but without the use of their names) to proprietary and secret remedies, and allow themselves to be made, as a medical man declared in a public address, "the catspaw and fool of the fraternity of the secret remedy"; and that there are medical men who prescribe to their patients remedies of this class of whose composition they are themselves largely ignorant. We have evidence in two cases of medical men acting as directors of companies manufacturing secret remedies.

The evil of proprietary medicines developed, perhaps, to a greater extent in America than in this country. The evil first became obvious about 1879, and early in the century the position was defined as follows by Dr. Simmons[3]:—

> Conditions in this regard had become so disgraceful . . . that there seemed to be no statement too silly, no claim too extravagant, and no falsehood too brazen for use by those who wrote the advertising literature that physicians
> are asked to read and believe. . . . In brief, this busine
> the annual profits of which run into millions, has grown un
> the use of proprietary medicines by many physicians h
> almost displaced the use of the individual official drug.
> has checked advance in scientific methods of treatme
> inhibited intelligent clinical observation, and developed
> optimism that is unwarranted by facts, an optimism th
> is more fatal than the most radical therapeutic nihilis
> But above and worse than all, this commercialised mate
> medica has blighted our literature by debauching o
> medical journals and even by tainting our text-books.

These are strong words, and picture an evil som
what worse than any that we have in this count
to-day. These evils produced, however, a reacti
in America, and steps were taken to check the e
whereas in our country it still flourishes unchecked.

AMERICAN AND BRITISH METHODS OF COMBATING QUACKERY.

The American Medical Association in 1905 appoint
a council on pharmacy and chemistry composed
leading chemists, pharmacologists, and clinicia
These examined all proprietary remedies, and pu
lished a list and description of all such remedies
conformed to certain simple rules. This list
published annually under the title of "New and No
Official Remedies."[4] Substances which are reject
are dealt with in the volumes, "Nostrums a
Quackery" and "Propaganda for Reform." The ru
upon which the council worked were roughly as follo
The drug must not be of secret composition, must n
be advertised directly to the public, and must not
advertised indirectly to the public by means
literature sent with the bottle stating the dise
it is intended to cure; the name must not sugg
therapeutic claims; unwarranted, exaggerated,
misleading statements as to the therapeutic va
must not be made; and no article is accepted which
useless on account of its unscientific compositi
Of these rules the last two are obviously larg
matters of opinion, but are perhaps the most import
of all. The American medical practitioner, therefo
who is deluded by specious advertisements i
recommending some useless nostrum, has only him
to blame, since he is acting against the conside
advice of a body of expert opinion.

In other countries also an attempt has been made
set up some machinery to judge the claims of adverti
ment of proprietary articles. The *Medical Journal*
Australia,[5] for example, has arranged to cond
analysis of Australian proprietary products submit
for advertisement. In Holland[6] the Rijks-Institu
voor Pharmace Therapeutisch Onderzoek has c
ducted a series of analyses on patent and propriet
preparations. In the case of the latter the combi
chemical, pharmacological, and clinical tests ha
been undertaken, providing very valuable informati

In this country valuable work has been d
by THE LANCET in publishing chemical analy
of proprietary preparations. The British Medi
Association ten years ago did a particularly valua
public service in publishing the two excellent volum
"Secret Remedies, What They Cost and What Th
Contain."[2] The British Medical Association, moreov
has passed various resolutions regarding preparati
which it is prepared to accept for advertisement in
publications. The most important regulations exclu
advertisement containing any demonstrated fa
statement, and preparations the principal ingredie
of which are not disclosed to the profession, a
preparations which are advertised elsewhere in
misleading or objectionable manner.

THE NEED OF EFFECTIVE CONTROL.

The measures which have been taken in Engla
are of value, but I think that it is clear that nothi
short of an organisation permitting extensive chemi
and pharmacological tests, and in certain cases ev
clinical tests, is sufficient to give reliable informati
on the really important point—namely, whether t
therapeutic claims made for a proprietary remedy
based on reasonably satisfactory evidence. Americ
experience has demonstrated that it is possible
provide such a source of information, and that it is

great service to the medical profession, but it has also shown that the work is difficult and expensive, and that if effective is certain to arouse furious opposition from the vested interests it injures. The object of my paper is to point out the desirability, nay, even the necessity, of having some organisation in this country to perform a similar work.

The Principles of SYMPTOMATOLOGY:

AN INTRODUCTION TO A NEW OUTLOOK IN MEDICINE.

BY SIR JAMES MACKENZIE, M.D. EDIN.,
F.R.C.P. LOND., F.R.S.

(From the St. Andrews Institute of Clinical Research.)

IN THREE PARTS.—PART III.

In Part I. (THE LANCET, *Nov. 3rd) there was outlined the general problem of ill-health and the new outlook in its respect. The principle of the "reflex arc" was explained. In Part II. (Nov. 10th) the cell and the law of fluctuation were considered and the afferent nervous system and the generation of impulse.*

8. STIMULATION.

We have seen that individual cells vary in their excitability—the process of recovery after stimulation varying according to a variety of circumstances. The question has to be considered how these cells act when in a community as when they constitute an organ. We know that organs vary in their functional activity, and there must be a great difference in the activity of these cells when the organ is working at the full extent of its powers and when its functional activity is reduced to the quiescent or resting stage. In the description of "fluctuation" it was suggested that when an organ is acting at full activity all the cells may be engaged, but that as it passes into quiescence some of the cells gradually become less excitable and take longer to recover, so that at one time one group of cells is active and at other times other cells are active, and in this way is brought about that variation in the activity of organs which is necessary to meet the requirements of the body in the ever varying circumstances of life.

As we proceed in our investigation we find this fluctuation universal, and it is impossible to understand such subjects as the stimulation and functional capacity of organs unless it be taken into consideration. To show the importance of fluctuation it may suffice to call attention to a factor which lies at the root of every problem—namely, stimulation. The varying activity of an organ is frequently due to the increase or decrease of nerve stimulation. When a nerve is stimulated the accepted teaching is that if it responds it does so with all its power, whether the stimulus be a weak one or a strong one, following the law of "all or nothing." When, then, a nerve is stimulated and an increased activity is shown by the organ which the nerve supplies, the response of the organ cannot be due to the *strength* of the stimulus, inasmuch as each nerve response is maximal. The only other alternative is that it must be due to an increase in the number of impulses.

The question then arises: In what way can the number of impulses be increased? The answer is simple, either by the increase of the number of impulses in a unit of time, or by an increase of the number of cells (neurones) taking part in the stimulation. It was not easy to decide which of these two ways are concerned in stimulation, until we applied the results of our observations on the skin, to which reference has been made. It was found that there were really no permanent "hot and cold spots." At one time small areas were sensitive and other areas were insensitive. At other times the sensitive areas became insensitive, and the insensitive areas became sensitive.

One aspect of the problem of stimulation was solved in a simple manner. A mustard leaf was applied to the skin and it was afterwards found that practically every point of the surface became sensitive to warmth. The conclusion drawn from this experiment is that stimulation means an increase in the number of receptors rendered active. Applying such results to the explanation of stimulation, a quiescent state means that all the cells of an organ are not acting, but when "stimulated" more or all of them become active. The application of this law of fluctuation to the interpretation of normal reactions as well as symptoms, clears up many obscurities. The law of "all or nothing," for instance, which has been accepted as explaining certain of the features of nerve activity and of the heart is wrongly applied in that while it is true of the individual neurone or of the individual muscle fibre, it is not true of the organs of which they are constituent elements. The recognition of this permits us now to understand the ability of organs like the heart to respond to effort, for the commonly accepted law that when the heart responded by "all or nothing" prevented us understanding how it could vary its activity, and rendered it impossible to understand the production of heart failure. The manner in which an excitable part of the reflex arc may increase the number of impulses which reach the effector organ and produce a symptom is explained by the law of fluctuation. Under normal circumstances, and especially when quiescent, only a portion of the cells which constitute a unit in the reflex arc are functioning. Certain agents, as a rise of temperature, the toxins of disease, or a drug, increase the excitability of a unit by increasing the number of cells which are functioning at a given time. The result will be that a stimulus reaching this unit will, under normal circumstances, excite only a few cells of that unit, but if rendered excitable under the influence of the factors or agents mentioned above, the same stimulus will set in action a much greater number of cells.

As this variation may take place at different parts of the reflex arc, we find symptoms due to disturbances at the receptor or in some part of the conducting system, or at the effector part of the process. This is well seen in the case of the heart. In the normal acting heart its rhythm is dependent upon the pacemaker—the sino-auricular node, Fig. 4. An increase in rate may arise from an increase of impulses at the receptor end of the reflex. An increase in the heart rate has been shown to be produced by contraction of the muscles of the calf (Fig. 7). Here the increase of rate is due to the increase in the number of impulses produced by the contracting muscle.

Another proof of the production of symptoms by diminished resistance to stimulation is seen in the different ways in which vomiting is produced. The production of vomiting by an increase of impulses will be commented upon in dealing with the contraction of hollow viscera, as in renal colic. Vomiting may be produced by a stimulus which in ordinary circumstances has no such effect. When a person sickens of some febrile complaint, or in transient attacks of ill-health (like migraine), sights, sounds, or smells, which in health produce no effect upon the processes concerned in the act of vomiting, may readily provoke nausea and retching. Emetic drugs act in the same way. They do not themselves produce vomiting, they merely lower the resistance to stimulation of some part of the reflex arc, so that impulses which in health would produce no result, in these altered circumstances produce vomiting. Strychnine and the toxins of rabies do not produce convulsions, they merely render certain parts of the reflex arc so excitable that normal impulses reaching them produce an exaggerated effect. A decayed tooth often sets up pain and a hypersensitive state of the neighbouring tissues. Sometimes the skin of the cheek becomes hypersensitive, so that stroking of the skin or the hairs of the cheek produces pain, while on the other cheek the same stimulus produces only the sensation of touch.

An increase in the sensitiveness of the skin and deeper tissues is common in a great many diseases, especially those of the abdominal organs. As the tissues which are rendered tender, and the area in which the tenderness occurs is very definite, the symptoms become a valuable diagnostic aid in the hands of those who know how to use it. It will become still more valuable when we discover the nature of the vital processes which are capable of producing it. Here, however, we are concerned with the changed conditions which render the skin and deeper tissues hypersensitive. The fact that stimulation of the skin provokes pain in a limited region, while the same stimulus produces only the sensation of touch or pressure when applied to other regions, indicates that somewhere between the receptor end of a nerve in the skin and the centre of consciousness there is a part whose resistance to stimulation is diminished. It would be too speculative to indicate the exact part—the recognition of the fact is sufficient for the present. The part of the central nervous system which is rendered irritable as shown by these localised areas of hyperalgesia is of small extent. A similar disturbance can be of greater extent and not necessarily associated with cutaneous hyperalgesia. In the condition called the status anginosus, the repeated attacks of angina pectoris have lowered the resistance to stimulation of some part of the central nervous system to such an extent that impulses from other regions than the heart may produce severe attacks of the pain, exactly like those of angina. The pressure of the stethoscope under the left breast, the movement of the left arm, may readily provoke an attack of agonising pain identical with that which follows bodily effort.

This facilitation of impulses may become generalised. In what is called neurasthenia we get evidences that many symptoms are rendered possible because of the lowered resistance to stimulation. Under such circumstances, the normal activity of an organ may result in the production of symptoms identical with those which are produced by disease of that organ. This lowered resistance is probably always due to some agent acting upon some unit of the reflex or regulating process—not affecting equally the processes of all organs. The result is an excessive activity of one or more organs, and the complaint is apt to be attributed to the organ whose activity is most prominent, hence the different names given to neurasthenia—gastric, cardiac, mental, &c. It is not always possible to recognise the primary agent in the production of neurasthenia, but occasionally we meet with instances that leave little doubt as to the origin of the trouble, as in the following.

A woman of 53 fell into ill-health, at first of a vague, indefinite "neurasthenic" kind. After some months the heart became irritable and pain was felt in the left chest. The pain increased in severity and occurred in attacks identical with those of angina pectoris and were looked upon by her medical attendants as being of this nature and of a grave type. After some months of this suffering an abscess burst into the bladder, and there was a profuse discharge of pus in the urine. From this date the attacks of angina completely ceased and a good recovery followed.

Surgeons are well acquainted with patients who suffer from severe gastric symptoms which lead to the view that there is some organic trouble in the stomach. Operations have repeatedly demonstrated that there is nothing amiss—organically—with the organ. The explanation seems to be that in certain states of lowered resistance the normal function of the organ gives rise to impulses which in health pas into the central nervous system unperceived, bu with the resistance of some part of the nervou system lowered, these impulses produce effects whic are looked upon as symptoms of disease.

Such seems to be the explanation of the followin experience :—

A youth suffered from an attack of gall-stone colic wit jaundice. There appeared after the attack of pain an are of cutaneous hyperalgesia—very acute—over the upp part of the abdomen on the right side. The stone wa passed per anum and the attack of pain ceased, but th hyperalgesia persisted for a few days. For some days aft when the patient took a meal he always suffered from pa in the epigastric region. As the hyperalgesia disappeare the pain became less severe, and when the hyperalgesi was gone the pain ceased. The interpretation we give such an experience is that the impulses from the musc fibres of the gall-ducts had temporarily rendered some pa of the central nervous system hyperexcitable, so that sligh stimulation reaching it, either from the skin or from th stomach, produced an exaggerated effect shown by pai With the gradual subsidence of the excitability the impuls from the skin and stomach ceased to produce pain.

While stimulation is due to the increase in th number of cells (neurones) participating in sendin the stimulus, it may also arise from increase excitability of the cells. Thus the s.-a. node whic regulates the heart beat can be rendered mor excitable in a number of ways. When the hea increases in rate it is due to the increased excitabilit of the s.-a. node or in abnormal rhythm of the a.- node (Fig. 4). That is to say, the recovery after th node has discharged its impulses is expedited. Thi may be due to a number of factors, as the rise temperature in feverish states, the action of dru and toxins, the increase of impulses from the brai or periphery, the diminution of vagal control, & If it is desired to understand the reason for a increased pulse-rate the application of the princip of the reflex arc compels the analysis to find th element at which the disturbance takes place an which of the causes just enumerated is operative.

9. Increased Impulses from Muscle.

While we have undoubted evidences that the cell of an organ generate impulses which can affect othe organs when they function we have to consider th part they play in the production of symptoms. I describing the production of goose-skin by stimulatin the skin it was shown that impulses were not sen only to one organ but spread widely, affecting number of organs, and the reason that such effect may not be recognised is due to the fact that we d not possess the means of detecting them in the health body. But when the agents of disease disturb th functions of organs by increasing or decreasing the activity, then the evidence of the presence of thes impulses may be detected in the disturbance of number of organs.

The muscular system, by reason of its wide rang of activity and of its susceptibility to stimulation, is fertile source for the production of impulses. When muscle is at rest it is in a state called "tone." Thi is maintained by the action of its cells, but all are no acting simultaneously. Each cell alternates betwee periods of rest and of activity. Muscles are liable t be stimulated to excessive effort, and when thi happens many more muscle cells contract and th impulses that arise are greatly increased in numbe These impulses being conveyed by afferent nerve into the central nervous system, stimulate the organ whose efferent nerves they reach into unusua activity. In this way is produced a peculiar train o symptoms the result of increased muscular activity.

It has long been recognised that some of the severes pains are associated with hollow muscular organ The explanation of this seems to be as follows Muscular organs consist of a great number of muscl cells. In the performance of their normal functio they contract with varying degrees of strength. S long as the contractions are moderate in degree n sensation is experienced. In these circumstances ording to the law of fluctuation, all the cells do t act at one time, some being active and passing o quiescence, while others pass out of quiescence o an active state. When moderate stimulation es place and the muscle is roused to greater ivity an increased number of cells are brought o action and fewer are quiescent. With still ater activity all the cells may be forced into ivity. Each cell when it passes into activity ows out an impulse and these impulses, we have n, are taken up by afferent nerves and conveyed o the central nervous system, where they stimulate nerves that supply other organs. There is bound be a greater outflow of these impulses with increased ivity, and in this way more afferent nerves are mulated, producing the results which occur in the ious colics—pain, nausea, vomiting, pallor, retching, . This interpretation also affords an explana- n why, of all the organs of the body, the hollow scular organs give rise so readily to pain and other nptoms, in that the muscle is the organ most ily stimulated to violent activity. We possess le or no power of increasing the functional activity the cells of the kidney, liver, pancreas, &c., and ice it is that severe pains are not associated with ections of these organs. That they may give rise disturbances of a milder sort is quite likely, eed, our researches indicate their presence, but so we are not able definitely to demonstrate their ation to this cause.

While the evidence which reveals the nature the stimulus which produces symptoms is mostly erential, rare opportunities arise which bring more closely to the real cause. The following perience demonstrates the relation of pain to iscle contraction :—

A man had a fistula at the umbilicus communicating with small intestine. An operation was decided upon. The ient refused an anæsthetic, and as the skin around the ning had ulcerated away an incision through the lominal wall was made with little or no suffering. The lominal cavity was thus laid open and numerous peritoneal esions broken down and the patient felt nothing. The vel and mesentery were cut and stitched and no sensation s felt. After preparing the upper part of the bowel it s wrapped in a warm cloth and laid on one side. During subsequent steps of the operation the patient frequently aned. He was asked if he felt pain and he replied that did. He was asked where he felt the pain, and he indicated h his hand that it was across the middle line at the level the umbilicus. It seemed at first that the pain might be e to the part that was being manipulated, but the pain s intermittent. Chancing to look at the prepared upper t of the bowel that lay on the left side of the abdomen, was observed that every few minutes a peristaltic wave sed over the lower portion of it, and when this occurred patient moaned in pain. To make certain that the pain s connected with the peristaltic wave the peristalsis s produced several times by lightly pinching the bowel. ery time the wave was produced the patient felt the pain d the pain ceased when the peristalsis stopped.

It is well known that the various colics—bowel, al, and gall-stone—are associated with more nptoms than pain, and there is good reason for erring that the processes which are concerned in ir production are similar to those which result in n. The following two observations illustrate the d of phenomena which occur during renal colic :—

A man, aged 30, had suffered for a year from occasional acks of renal colic, and one attack had been followed by maturia. He was a very intelligent man and was told to e every particular during an attack. The following is a nmary of his statement—the statement being illustrated the patient placing his hand over the regions mentioned : pain suddenly seizes him with great severity in the right ibar region, then after a few minutes it strikes into the nt of the abdomen over the iliac fossa. Then the belly omes hard and rigid. The pain then strikes down into inner side of the groin, the testicle is felt to be drawn up, l the pain then shoots into the testicle. The facts here cribed were corroborated by him in a few subsequent acks, each attack invariably pursuing the same sequence. tes made after an attack describe an indefinite area of aneous hyperalgesia over the iliac fossa, hardness and idity of the abdominal muscles over the right iliac fossa h great tenderness on pressing over the abdominal muscles and on the right testicle and on the spinal muscles in the lumbar region. The fact that the pain always started at the same place indicated that the stone remained fixed in its position, a view confirmed in that there was never any evidence of the calculus having reached the bladder. An X ray photograph failed to reveal the stone. He was operated upon and a small calculus about the size of a pin's head was found adherent to the apex of a calyx opposite the junction of the middle and lower third of the pelvis of the kidney. This was removed and the patient made a good recovery and remained quite free from all symptoms.

The conclusion suggested is that the presence of the calculus at times provoked the muscle of the ureter to violent peristalsis, and that this was the source of the impulses which provoked the train of symptoms.

A male, aged 34, suffered from severe attacks of pain in the abdomen accompanied by great hardness of the muscles of the abdominal wall. The attacks of pain were accompanied sometimes with vomiting, and as the bowels had not been moved and no flatus had passed the condition at first resembled that of obstruction of the bowel. An examination revealed a somewhat distended abdomen with great rigidity of the muscles. This form of contraction also affected the muscles of the anal sphincter, for it was with the greatest difficulty an exploring finger could be forced into the rectum. The patient's description of the pain, its site and radiation was rather confused, but at the end of the examination he was seized with an attack of pain. The pulse became slow and soft. He became pale and sweat poured out. He was asked to put his hand where he felt the pain and he indicated the left lumbar region. As the pain increased in severity it shifted round to the front and remained definitely fixed over the left iliac fossa. After a few minutes it passed off. A diagnosis was given of renal calculus. An opiate was prescribed and next day a calculus the size of a pea was voided with the urine, and all the symptoms disappeared.

The group of symptoms just described as occurring in attacks of renal colic, involves the abnormal activity of afferent nerve fibres. In such instances we see the wide range of their effect, inasmuch as they convey impulses which disturb many organs widely sundered, as in the production of nausea and vomiting, depression of the heart's action, pallor and sweating, contraction of the abdominal muscles, pain, and cutaneous hyperalgesia. We can further infer that in the normal processes of life impulses are conveyed from all active organs into the central nervous system, and these impulses act upon the processes concerned in regulating those organs which give rise to such striking symptoms—as the brain, heart, the stomach, the muscle of the abdominal wall, the vaso-motor system, the sweat glands, &c. The best example of this action is the pain set up by uterine contraction. All the phenomena just described as occurring in renal colic can be made out with each labour pain. The same phenomena occur even in the unimpregnated uterus during menstruation, or when a foreign body is introduced into the uterine cavity.

But there is more in the matter. It is customary to speak of such pain as being due to stimulation of a pain nerve which supplies the ureter or uterus. When all the facts are considered it will be found such an inference is unnecessary. The fact that vomiting occurs during an attack of renal colic does not imply that there is a special vomiting nerve distributed to the ureter, or because the heart's action is modified that there is a special cardiac nerve, or because pain is felt that the ureter is supplied with a pain nerve.

It can be more reasonably assumed that the impulses which arise during violent contraction are greatly increased in number, and that the various disturbances (or symptoms) which result are due to the increased number of impulses which react on those parts or "centres" in the central nervous system which habitually receive the impulses in health. That is to say, pain does not arise in these muscular organs because they are supplied with a nerve whose special function is to convey a "pain" stimulus; but pain, like vomiting and other manifestations, is caused by the greatly increased number of impulses that reach the pain, vomiting, and other centres in the central nervous system.

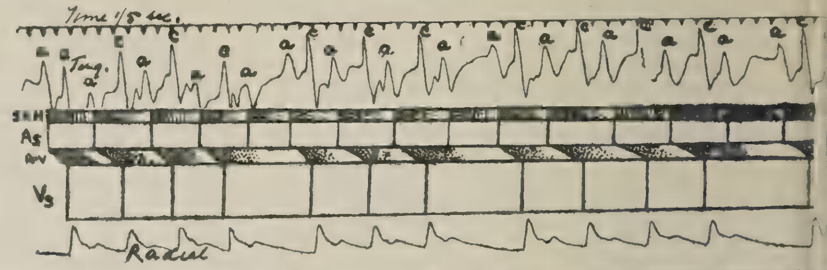
10. INHIBITION, BLOCKING OF IMPULSES, AND PARALYSIS.

We have seen that, as a result of disease, the impulses may be increased in number at their origin or during their transmission, and an undue activity of the organ may result, giving rise to symptoms. The reaction may be in the opposite direction, and depress or suppress the function of organs. This may be brought about in several ways, as by structural changes, or by defective blood-supply, or by the agents of disease acting upon the parts which regulate the organs inhibiting or blocking the impulses. It is the last of these that is being considered here.

The blocking of impulses is but an exaggeration of that normal increase of resistance to stimulation which occurs in every cell during and after exercising its function. The blocking of impulses at the auriculo-ventricular node affords the best illustration of the production of symptoms in this manner.

A girl of 14 recently fell ill of a slight febrile attack, during which her pulse became irregular. This irregularity continued for two days, after which the rhythm became regular and the girl made a complete recovery. A simultaneous record of the radial and jugular pulses (Fig. 8) shows that the auricle (waves, *a*, in the jugular record) contracted regularly, but that the ventricle (waves (*c*) and the radial pulse) did not respond to every auricular wave. This is brought out in the interpolated diagram. The shading in the space S.-A. N. represents the discharge of impulses from the sino-auricular node, the shading representing the refractory period. The down strokes in the space As represent the auricular systole (*a*) in the jugular tracing, and the down strokes in the space Vs represent the radial pulse (ventricular systole). The space A.-V. represents the auriculo-ventricular node. The shaded portion of the A.-V. space represents the period when the node was incapable of stimulation, and it is shown that every now and again the auricular impulses fell during this period and failed to reach the ventricle, so that a ventricular systole fell out—that is to say, the pauses in the radial pulse which produced the symptoms of irregularity were due to the blocking of impulses by an undue increase in the resistance to stimulation of the cells of the A.-V. node.

FIG. 8.



Tracings of the jugular and radial pulses. In the jugular tracings the auricular waves (*a*) regular, but the radial pulse shows intermissions. The waves (*c*) are due to the car and correspond to the radial beats. In the diagram the intermissions are shown to be to blocking of impulses at the A.-V. node. The down strokes in the space As represent auricular waves (*a*) in the jugular tracing, and the space Vs the ventricular systoles a radial pulse. The space A.-V. represents the A.-V. node, and it is seen to be here that block takes place—the shading in the spaces S.-A. N. and A.-V. represents the refract period of the sino-auricular and auriculo-ventricular nodes. The diagram illustrates principles of the reflex arc.

Another instance of the same kind is found in certain paresis or paralysis such as that which follows diphtheria. Here the toxin of diphtheria picks out certain parts of the regulating process, and blocks the impulses which should reach the muscle. The part affected is probably some part of the efferent or motor nerve to the muscle. In all likelihood the condition known as "suppression of urine" results from a similar disturbance. But we know so little of the processes that regulate the function of the kidney or other organs that it is not possible to hazard more than a guess at the cause of this and many other functional disturbances. Clear-cut examples of symptoms produced by hindering or blocking of impulses are not common, partly because we do not know how to detect them. This is due not only to our defective knowledge of the regulating processes, but also to the peculiar manner in which the suspension of activity is manifested. In the regulation of the functions of organs there are nerves whose functions favour and others whose functions depress the activity of organs, like those supplying the dilator and constrictor muscle fibres of the pupil and the vagus and sympathetic supply of the heart. Impulses from these nerves may be blocked. Blocking of impulses may affect the parts normally concerned in increasing the resistance to stimulation—i.e., inhibition. The removal of this influence permits the opposite influence to act unchecked, so that the blocking of impulses may result in the organ exhibiting signs of increased activity. This part of the subject becomes cleare from the study of the phenomena produced by th action of drugs and allied substances.

This blocking of impulses may result in paralysi The term paralysis is usually applied to the loss voluntary control over a muscle whose connexion wit the cerebral cortex is severed. It has been als applied to other organs whose functions are controll by nerves when this control is lost, as in the so-call paralysis of glands like the salivary, vaso-mot paralysis, &c. It is of great importance to recogni what happens when a muscle or other organ is depriv of its nerve-supply. It must be remembered th they are supplied with other nerves and with bloo and that the cells have functional potentialities ev when separated from their nerve-supply. Invest gation on these lines reveals a great many resul which give rise to symptoms of disease. Referen has been made to the fact that when a muscle los its connexion with a motor nerve it does not lie ine but passes into fibrillation. When the sino-auricul node ceases to act the auricle passes into fibrillati and flutter (see Fig. 6), and the impulses which t muscle fibres of the auricle throw out affect t A.-V. node, giving rise to very definite signs, such as rapid and irregular pulse (delirium cordis). It is ve likely that delirium, convulsions, migraine, a many other forms of cerebral attacks arise from loss of control of the higher centres over limited pa of the brain.

11. THE ACTION OF DRUGS.

In our attempts to classify symptoms according their affinity in nature—that is, according to processes whose disturbance resulted in the product of a symptom—we met with difficulties that seem insurmountable. For one thing, the agent wh reaction on the body produced the symptom co seldom be recognised; for another, when the pati became so ill that he had to consult the doctor phenomena were so numerous and varied that it difficult to detect their relation to an agent or to another. Recognising that symptoms were, a all, only a modification of normal processes, it possible by suitable means to modify these proce and produce phenomena identical with sympto Amongst these means was the giving of drugs. action of drugs is practically that of the action of toxins of disease, and it is often possible to imit disease states by drugs and similar agents as gl extracts, vaccines, &c. The advantage of this met is that we can observe the condition of the individ before the drug is administered both in health disease, and watch the way in which the drug pi out the tissue or organ on which it has a defi effect. Amongst those effects there may be one more which reveal the exact part or unit in the re arc on which it acts, and by analogy we can infer effect upon other organs where it is not possible learly to recognise the part it affects. In this vay a good deal of light can be thrown upon the ature of the symptoms of disease, as well as iving us a better understanding of the action of our emedies.

Although a good deal of work has been done on he action of drugs, the results have not been as uch used as their importance deserves, nor has the nportance of pharmacological experiment been fully rasped. We are greatly dependent on physiological xperiment for our knowledge of the functions of rgans, but there are great limitations to these methods, that there are whole fields which are beyond their rovince, such as the sensations and the afferent ervous system. It has already been pointed out hat the peculiar function of the afferent neurone lies the peripheral branches of the fibre, and experiments hich neglect this part, as in cutting and stimulation, ill fail to reveal the function of the neurone. By e use of drugs the nervous system remains intact, nd the manner of action of the drug and its effects semble more closely those of a disease agent than cutting experiment.

Though we are carrying on this line of investigation ur results are as yet too scanty to justify us in dealing ith them at any length. Here we give some results f our study of a few drugs merely to indicate the nes we pursue.

It may be considered that all drugs which produce e or more demonstrable effect produce at the same me a great many more effects which are unrecognised mply because we do not possess the means of detecting em. It is at times possible to recognise with fair rtainty the manner in which a drug acts on a articular organ, and it may be reasonable to infer at it acts on the same kind of tissue in other organs though the effect as seen by the observer may be fferent. Such clearly recognised effects are more fely detected when the dose is minimal, for the ason that in large doses not only may confusion ise from the number of effects, but the disturbed nction of one organ may modify the action of other gans, just as happens in certain forms of ill-health. he action of atropine, alcohol, digitalis, and chloro-rm afford good illustrations of the help we may get om comparing the production of symptoms with e effects produced by drugs.

Atropine.

The heart rate is dependent upon the sino-auricular de, as it discharges the impulses which stimulates e heart to beat. The cells of this node are peculiarly nsitive to agents which increase or decrease their citability. The chief agents are the influences the vagus and sympathetic nerves—the vagus creasing the excitability and the sympathetics creasing it. Such effects are spoken of as inhibition d stimulation, but when we inquire more closely to their nature we find that on the one hand the gus delays the metabolic process within the cells the S.-A. node, so that it takes a longer time for the lls to renew their store of energy, and become sus-ptible to stimulation, and on the other hand the mpathetic acts by hastening the metabolic process. ropine acts on the terminal branches of the vagus rve, not on the nerve cell, but on the part of the urone concerned in the special function of the nerve. a result the metabolic process in the cells of the A. node, to which reference has been made, is not layed by the vagal effort, and the heart's rate comes increased. Atropine acts on the terminal anches of that portion of the cranial nerve which pplies the pupil and ciliary muscles. The effect re is to prevent impulses reaching the constrictor the pupil and the ciliary muscle, so that these scles cease to act. While the atropine acts upon same part of the nerve in both cases the effect different. Suspension of vagal activity results in stening the metabolic process in the S.-A. node; spension of the activity of the third cranial nerve ults in the blocking of impulses to the muscles. ropine acts on the brain and produces delirium.

Alcohol.

It is not easy to explain satisfactorily all the phenomena due to the effect of alcohol, particularly as alcohol causes a dilatation of the blood-vessels and thus influences organs by an increased blood-supply. But certain manifestations can be recognised and referred with fair certainty to their cause. At a certain stage of intoxication certain muscular movements become impossible. These movements belong to a very definite group—namely, those which are acquired late in life, such as the movements involved in speech, in writing, in giving expression to the face, and in binocular vision. It is to be observed that the muscles in those cases are not paralysed, for however unsteady the hand may be it can still grasp the glass and raise it to the lips, and however difficult speech may be the same muscles when employed in swallowing are still shown to be active. It is manifest that here the impulses that should reach the muscles from the brain by the latest developed channels are blocked. This would suggest that in the later stages of alcoholism, whether resulting in a profound sleep or noisy delirium, processes of a similar kind are affected.

12. Increased Activity from the Blocking of Impulses.

The object of this analysis of the phenomena produced by atropine and alcohol is to disentangle the confused mass of symptoms which may be found in a sick man, under the influence of a drug or of the toxins, of a disease. The recognition of the nature of a single phenomenon may render it possible to find out the nature of others. In this attempt we must not be misled by the superficial character of the phenomena or symptoms, for they are but the expression or result of a disturbance, and are not themselves the cause of the disturbance. Though we may find an organ exhibiting signs of increased activity, we are not justified in concluding that the organ has been stimulated or that the agent causing the disturbance acts by stimulating the organ.

There are processes which are concerned in increasing and decreasing the activity of cells and they are normally in continuous action, the one restraining the activity of the other. If for any reason one of them ceases to act, the other is unrestrained, and there results an increase or decrease in activity of the organ. This balancing of activity is in action in regulating the heart rate and in regulating the size of the pupil. The actions of the vagus and sympathetic are antagonistic, because the function of the vagus is to increase the resistance to stimulation, while the sympathetic decreases it.

The removal of vagal influence over the heart allows the sympathetic to be unchecked, with the result that the heart's rate becomes greatly increased. Atropine acts in this way, so that if we did not know how it acted we would be inclined to say that atropine was a "cardiac stimulant." In the same way atropine blocks the impulses from the third cranial nerve, so that dilatation of the pupil results, and we say that atropine causes dilatation of the pupil, whereas, what it really does is to allow the dilator pupillæ to act unchecked. The delirium which results from atropine or alcohol is described by authorities as being due to these drugs "stimulating the brain." It is more likely that the condition is one in which a controlling or restraining influence is lost. This is specially likely to be the case when we reflect what a slight quantity of an agent may produce the effect. Thus, a few drops of atropine put into the eye may produce not only a dilatation of the pupil, but also delirium. It is a reasonable inference that the drug acted in the eye and in the brain on similar structures.

From this way of reasoning we would infer that delirium is the result of the blocking of impulses from the cells which regulate or control the centres which are concerned in thought and in executing movements. In describing the effects of alcohol it was pointed out that it also acted in blocking nerve impulses. This would suggest that in the later stages of alcoholism, whether resulting in a profound sleep or in noisy delirium, other neurones are affected in the same way. This seemingly conflicting effect, when a drug leads to an increased activity of one organ and a decreased activity of other organs, is not uncommon. The action of digitalis, for instance, undoubtedly leads in some cases to a decrease in the pulse-rate, while at the same time it may increase the susceptibility of the vomiting centre. It is commonly assumed that the main action of the drug is upon the heart, whereas it acts far more frequently upon the vomiting centre. In people with healthy hearts digitalis has little or no effect, but in most people it produces nausea and vomiting. It is chiefly in diseased hearts, as in auricular flutter and fibrillation, that its effect is predominantly cardiac, and that for a reason which does not concern us here.

Such a drug as digitalis has other effects than vomiting and decreasing the heart, but they are not always perceptible. Diarrhœa may result. Mental disturbances of a slight degree are not uncommon, though occasionally they are very striking. A young woman with mitral stenosis was curiously susceptible to digitalis, partial heart-block being readily produced. One day, while under the influence of the drug and engaged in her household duties, she suddenly lost all consciousness of her surroundings and found herself sitting sobbing and crying at the fireside of a sister a mile away from her home. How she came there she did not know. An hour previously she had walked in and sat down and would not reply to her sister's inquiries. Toxins of disease act in a similar way. A man while recovering from an influenza was occasionally seized with attacks of noisy delirium; during the attack the pulse was slow and irregular, due to partial heart-block—of the kind produced by digitalis. After a few weeks the attacks ceased and neither heart nor brain symptoms of any kind were afterwards manifested.

Not only delirium but temporary insanity occurs after an influenzal attack; some people readily become delirious with a slight febrile attack. Insanity from toxic causes, as during the puerperium, or during a *Bacillus coli* infection, is not uncommon. It is worth considering how far the disturbances that lead to delirium and insanity are related to the disturbances that produce the symptoms of disease in other organs.

13. THE ACTION OF CHLOROFORM.

The inquiry into the nature of symptoms and the phenomena of ill-health has shown that problems in medicine can be approached in different ways, each of which throws a new light upon the subject. In this way principles emerge whose application helps the solution of problems. Many years ago, in a discussion, the late James Ross threw out the suggestion that there was a tendency for disease to affect the latest developed structures. We dimly perceive that this idea may explain a goodly number of the phenomena of ill-health if we knew how to apply it. I have attempted to apply the conception to discover the action of drugs, and studied it particularly in the action of chloroform. When Ross propounded this idea over 35 years ago, I was devoting much time trying to find out the parts of the nervous system concerned in the production of pain. At that time the researches of Gaskell on the sympathetic system were beginning to be applied, particularly by Ross, to the interpretation of symptoms, and as a result of a great many observations I put forward the view that of the two great divisions of the nervous system—the cerebro-spinal and the sympathetic (now called by Langley the autonomic and including the sympathetic and para-sympathetic)—pain was an attribute of the cerebro-spinal system. In this view the cerebro-spinal system and the "sympathetic" were closely allied, so that when pain did arise from visceral stimulation it was by impulses conveyed by the afferent sympathetic nerve to the cerebro-spinal system, just as impulses from the viscera caused contraction of the voluntary muscles seen in the hardening of the muscles of the abdominal wall in visceral diseases, and in the "organic reflexes."

I went further and suggested that of the tw systems the sympathetic (controlling the "vegetative functions) was the older, and was the representativ of the nervous system in the invertebrates, while th cerebro-spinal was more recent and appeared first i the vertebrate animals. At this time embryologist and anatomists taught that the sympathetic wa an outgrowth from the cerebro-spinal system, an therefore the more recently developed. The sugges tion that the sympathetic system was the oldes was not accepted, but it is of interest to find tha this suggestion is now receiving some support fro embryologists.

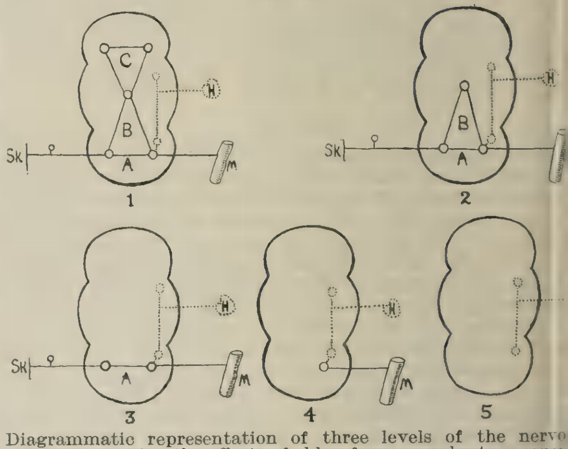
At that time I recognised that this was a matt which went to the root of symptomatology, and tha no clear conception of pain and associated phenomen (such as cutaneous hyperalgesia, muscle contractio nausea, and vomiting, &c.) could be obtained until th question was settled. I therefore sought for oth evidences in the effects of diseases and of drug The study of the effects of chloroform seemed t my mind to be if not conclusive at all events strongl confirmatory of the view that the autonomic syste is the more archaic.

The assumption is that the drug affects in order th nerve cells according to their development, the late developed being first affected. In this way the who cerebro-spinal system of nerves is put out of actio (paralysed). Organic reflexes are assumed to ari in the autonomic system, and to be expressed (in pa at least) through the cerebro-spinal, so far as th action of voluntary muscles are concerned, as i respiration, defæcation, micturition, &c.

In the diagram Fig. 9 an attempt to depict th effects of chloroform is given. The matter is repr sented in a broad fashion, for I am too ignorant the constitution of the nervous system to descri the details. This description is based upon we recognised facts and is an attempt to explain them.

Three levels of the cerebro-spinal system a represented in the diagram Fig. 9 (1). The low level (A) representing a simple reflex, the part represents the sensory system of the external bo wall, while M represents the voluntary muscul system in whole or in part. The second level represents the portion of the brain where movem are coördinated, the higher level (C) represents t portion of the brain concerned in consciousness. T dotted portion represents the autonomic system nerves concerned in the organic reflex of respirati and in regulating the heart.

FIG. 9.



Diagrammatic representation of three levels of the nervo system showing the effects of chloroform on voluntary musc Muscle contraction can result from three levels of the cereb spinal nervous system and from the autonomic nervo system, represented by the interrupted lines. Chlorofo acts by blocking impulses to the muscle first from the high level C., next from the mid-level B, and then from the low level—the cutaneous reflex at A. After these are thrown of action impulses from the autonomic system and t respiratory centre continue to excite the muscles, till fina with the blocking of impulses from this latter source respi tion ceases and the heart (H) gradually ceases to beat.

On the administration of chloroform the higher centre (C) is the first to be affected (Fig. 9 (2)). The patient is unconscious but capable of muscular movement, and is often delirious because the portion C becomes partially blotted out. A further stage of chloroform anæsthesia represents the middle level gone (Fig. 9 (3)), when the patient lies in a seemingly profound sleep, but reflex contraction of the muscle occurs when the conjunctiva is stimulated. Movements are also provoked if a knife cuts the skin. At this stage the voluntary muscles concerned in the respiratory movements are acting. The next stage shows the abolition of the cutaneous reflex, the stage at which operations can be undertaken (Fig. 9 (4)). The only movements of the voluntary muscles now are those of respiration. The contracted abdominal muscles, the result of visceral disease, if present, are still unrelaxed, and may remain so even when the anæsthesia is profound—that is to say, impulses reaching the abdominal muscles from the viscera are unaffected by the chloroform. The next stage is when the voluntary muscles cease to act and respiration stops, on account of the blocking of impulses to the motor nerves in some part of the respiratory reflex arc (Fig. 9 (5)). Following upon cessation of breathing the heart gradually ceases to beat and death results.

Such is briefly the course of events in the anæsthesia of a healthy individual. The occurrence of death under chloroform, when not due to a cessation of respiration, is due to the disturbance of certain processes in the heart itself, which renders them more susceptible to the drug. How dependent the heart is for its action on a suitable supply of (aerated) blood is shown by the following experience. While feeling the pulse of a patient being operated upon it was found to become slow, and on looking at the patient it was evident that although he was making the movements of respiration, no air was entering the lungs because the tongue had fallen back. Opportunity was taken to watch this effect when the pulse steadily fell from 60 beats per minute to under 20 beats per minute, when the patient had suddenly a slight epileptic attack. The fall in pulse-rate was due probably to vagus inhibition by asphyxia blood acting on vagus centre. When the tongue was pulled forward the patient breathed deeply and the heart's rate became at once increased to 70 beats per minute.

It is to be observed from the foregoing description of Fig. 9 that the inactivity of the voluntary muscles was due to the blocking of impulses, first from the centre of consciousness, then from the second level, then from the periphery, and finally from the centre of respiration. In Fig. 3 it was shown that a voluntary muscle could be made to contract by impulses from four different sources. It will be seen that chloroform in turn blocks these impulses or "paralyses" the nerves from these sources.

This description of chloroform effect is given mainly to indicate certain lines which can be pursued in different spheres of medical research, not only in elucidating the nature of symptoms and the action of remedies, but also in solving the problems of development.

DONATIONS AND BEQUESTS.—By the will of the late Mr. Frederick Wolfe, retired solicitor, the testator left £2000 to the Middlesex Hospital, as to one-half for the Endowment Fund and one-half for the Cancer Research Fund, and £1000 each to the Charing Cross Hospital for the Endowment Fund and to King Edward's Hospital Fund for the Endowment Fund, as well as £500 each to the Cancer Hospital, Fulham-road, and the National Hospital for the Paralysed and Epileptic. Several hospitals to which the testator had been an annual subscriber will receive £100 each, and subject to certain bequests the residue of the property will be divided between the Charing Cross Hospital and the Middlesex Hospital for the Endowment Fund, and the Cancer Research Fund respectively.—During the past month the Manchester Royal Infirmary received two legacies: £1000 from the late Rev. John Jones Dixon and £200 from the late James Reece. Amongst the donations and subscriptions were £1250 from the Manchester and Salford meat trades, and from other trades and societies sums totalling £585.

SOME ASPECTS OF THE
TYPHUS PROBLEM IN SOUTH AFRICA.

BY H. F. SHELDON, M.R.C.S. ENG., D.P.H.,
ASSISTANT HEALTH OFFICER FOR THE UNION OF SOUTH AFRICA.

TYPHUS is very prevalent in South Africa, mostly amongst natives, more than 8000 cases a year being notified. As full notification is impossible under primitive conditions, this number probably means 24,000 actual cases. About 300 cases a year occur in whites, but these are accidental infections from natives.

Difficulty of Diagnosis.

Typhus has probably occurred in South Africa since the earliest times. The natives are familiar with the disease and, as their habit is, pick out a salient feature for naming purposes. I-Fiva-Myama means literally the black-tongued fever, referring, of course, to the pronounced typhoid state which so readily develops. Only in the last few years has "black fever" been identified with typhus. Mitchell, Cranke, and Rees, the last of whom must be added to the long list of those who have lost their lives in typhus investigation, were the first to realise the identity of the two diseases. Only now is typhus coming into moderate prominence. The presence in a native district of a 14-day fever about which the local practitioner is unable to make up his mind is very suggestive of typhus. Such inability to make up the mind does not indicate a lack of diagnostic acuity; the raw native does not usually send for the European doctor, and if he does, one visit does not furnish all the clinical evidence necessary for an exact diagnosis. This is especially so as typhus in South African natives in no way conforms to the classical description of the malignant and terrifying type known to the older generation of European practitioners. Perhaps the most important difference is that the rash is not seen on the dark skins of the primitive native races. In speaking to Dr. Jacottet, of Matatiele, who was in Serbia during the epidemic, he told me that if it were not for the absence of the rash he would have readily diagnosed the 14-day fever prevalent in his district as typhus.

Mildness of South African Typhus.

Another difference is that the South African type is a comparatively mild one. Reliable statistics are impossible to obtain; my impressions are derived from the opportunities I have had in the past two years of observing innumerable cases both in hospital and in their own rural setting. For these opportunities I have to thank my chief, Dr. J. A. Mitchell, whose name I have already mentioned in connexion with pioneer work in the recognition of South African typhus. Certainly typical cases exist, especially amongst middle-aged people; these have sudden onset with pain in the neck and body, high temperature, rapidly developing fever, prostration, red eyes, stupid face, dry brown tongue, delirium, deafness, absence of knee-jerks, and death from the eighth to the twelfth day. In such cases blood-stained purple spots or even plaques may be visible in spite of the darkness of the skin. Small hæmorrhages may occur apart from the spots giving rise to a flea-bitten appearance. But associated with such cases are others of a much milder type dwindling down to a few days' pyrexia with a few added symptoms. I have not yet had the opportunity of confirming Jacquot's observation of "typhusisation" in subjects exposed to infection taking the form of malaise, slight fever, loss of appetite, headache, and intellectual debility for several weeks.

In white or light-skinned people the rash is prominent, varying from transient macules which fade on pressure, through brown-stained spots which do not so readily fade, to distinct blood-stained spots. The milder the case the less the rash. The shading of spots showing deep in the skin is spoken of as subcuticular mottling. A certain amount of bronchial catarrh is not uncommon, but the broncho-pneumonia which is such a marked feature of European typhus is only rarely seen.

Distribution of Population.

In South Africa one has to deal with large native areas on the one hand, and rural and urban mixed areas on the other. In urban areas the means exist for enforcing cleanliness and actively suppressing the disease; in mixed farming areas the natives are greatly under the influence of the whites as regards health, and in the large native areas such health influence is absent. Of these native areas the Transkei is typical; here a large portion of the Eastern Cape is divided into 27 districts, having a total population of over a million natives. In each district is a magistrate and a part-time district surgeon; round each magistracy springs up a little European village. In a district with a native population of 30,000 there may be 20 or more local areas, each under the control of a native headman; a headman's area (called a location) has a very scattered native population. A kraal, the habitation of one family, consists of several huts and a neighbouring rough enclosure for a few stock, sheep, or goats that the family is lucky enough to own. Kraals are often aggregated into scattered villages. Topographically, the country varies from undulating veld to rugged mountain areas. A few roads are supplemented by rough tracks which dwindle into paths; except on the roads wheeled transport is impossible. The natives use a very crude form of small sledge drawn by oxen, but many places are only accessible on horseback.

Such a native area soon becomes a nest of typhus and other diseases. Suppression of typhus in such an area presents the greatest difficulty.

Social Conditions of Natives.

The habits and social conditions of the natives are such as completely to nullify the advantages of living in sunshine and vast open spaces. In an isolated kraal consisting of five round mud huts, each without any ventilation or lighting except a small door, one may find at night 10 or 15 persons closely shut in, lying on the floor, each completely enveloped in a kaffir blanket. Native custom requires unlimited hospitality. Interchange of lice under such conditions is unavoidable. Nor would the presence of a typhus case or convalescent alter the customs of the house. A fundamental difficulty of dealing with typhus in natives is their ignorance of the infectiousness of disease. Witchcraft and malign influences they believe in, but disease germs and their transmission from one to another are to them inconceivable.

Knowing as we now do that typhus can be communicated from person to person by the louse alone, the suppression of typhus becomes a matter of enforcing cleanliness. Amelioration of a native's social conditions must necessarily be a long process; increased agricultural productivity may in time to come enable him to produce not only enough for his own bare existence, but a surplus which will give him prosperity and the luxury of cleanliness. It may not be literally true that the first act of the Pilgrim Fathers was to fall on their knees and the next to fall on the aborigines, but their advent marked the introduction of conditions most deadly to the aboriginal races. Tuberculosis takes terrible toll of uncivilised man brought into contact with those who have enjoyed the advantages of urban civilisation. The wearing of European clothes without opportunities for cleanliness tends to give the louse unlimited scope. The red ochre and fat with which the raw native anoints himself are inimical to lice, and the loose blanket which can be thrown off and laid in the sun is not an ideal home for them, having neither folds, seams, nor cosy corners. Generally speaking, however, all natives are lousy, in the head if not in the body. Old people are the worst; an old native woman long past sex interest is a neglected figure. The difficulties of personal cleanliness in rural natives are not realised. One set of dilapidated clothes worn continuously, the nearest washing water some miles away, the weather sometimes very cold, no soap and no money to buy any—these factors indicate some of the difficulties. The native now moves wider afield both for livelihood and amusement, with corresponding effect on the epidemiology of typhus and other infectious disease. One may say he is in process of Europeanisation and urbanisation, of which neither is an unmixed blessing.

To attain a standard of cleanliness which will eliminate typhus may be realised in the dim future. meanwhile, urgency measures are required. If you tell a native that the louse is the cause of typhus he laughs at you. He well knows that the louse has been the constant companion of himself and his ancestors; moreover, the statement would not be true, for the *infected* louse is responsible. The immediate problem, then, is to get rid, not of the louse, but of the infected louse. For this three things are necessary: First, to find the cases; the second, a portable rapid disinfestor; and the third, a reliable insecticide which will be attractive to natives. Scouts to find the cases are easily found and trained.

De-verminisation Apparatus.

To work out a portable, rapid, and efficient de-verminising apparatus has been more difficult. Water and fuel are often unobtainable. Any process which wets the clothes is too slow for practical purposes and raises intense objections. All schemes for general de-verminisation are too costly. Natives are only amenable when frightened by actual contact with the disease; like all savages, they lack foresight. The difficulty has been solved by the use of a canvas cover placed over a collapsible wood frame, into which hot air from a large blow-lamp is introduced through a short length of light iron pipe. The hot air is distributed and danger of fire is avoided by the use of a perforated galvanised iron baffle. The temperature is regulated by a Centigrade thermometer slipped into a wooden guide let into the top of the tent. The whole apparatus with the pack-saddle on which it is carried weighs about 116 lb. The tent is 4 ft. 7 in. high, 4 ft. 4 in. by 3 ft. 3 in. long and wide, and of stout canvas. The sides are prolonged into 4-inch flaps which rest on the ground and may be weighted with stones, earth, or other material. The frame is of wood, the uprights about 4 ft. 11 in. in height, being pointed for driving into the ground. The sidepieces, two long and two short, corresponding to the dimensions of the tent, are joined to the tops of the uprights by detachable three-way angle-pieces made out of 3-inch lengths of light but strong metal tubes acetylene-welded together. To prevent the tent catching fire over the hot-air pipe, an oblong piece of asbestos cloth, the lower edge of which touches the ground when the tent is in position, is inserted midway in one of the long sides. The pipe is of black iron acetylene-welded. The baffle consists of a perforated plate of light galvanised iron 2 ft. 4 in. wide and 3 ft. long; 6 in. of the length, bent at right angles, raises one end from the ground. The unbent edge rests over the inner end of the pipe but raised level by a couple of loose stones. The plate, including its bent end, is perforated by closely set holes 1 inch in diameter, except for a narrowing area 16 in. wide and 12 in. long, where the hottest part of the draught enters. The best blow-lamp is made by Christopher Collins, Ltd., St. Paul's-square, Birmingham. No. 100.

The gallon-sized "Corona" lamp made by Messrs. Howes and Burley is satisfactory; other lamps have proved disappointing. The six cross-pieces, on which to hang the clothing, are light but strong, preferably of bamboo; they are lashed with a continuous length of thin rope on the upper surface of the long sides of the frame. Stiff wire double-hooked loops are passed over the bamboo crossbars, four to each, for smaller garments. The best pack-saddle is the G.S. military pattern.

To work the disinfestor first set up the frame. Dig a channel for the pipe to enter under the asbestos insertion (to save the asbestos from the wear which takes place if the pipe is simply placed on the ground and the asbestos cut snugly to fit it). Clear enough earth from the inner end of the pipe to allow free access of air under the baffle. Dig a hole outside the tent deep enough to bring the flame of the blow-lamp opposite the pipe. Place the baffle-plate in even position as described. Clothing must hang over the bamboos or on the hooks *so as to leave a clear space between each row*, and no clothing must hang over the frame. If these points are not carefully attended to the heat distribution will be uneven, the disinfestation patchy, and the thermometer may not indicate the actual heat in places, so that there may be scorching. Clothing should, of course, hang well clear of the baffle.

Cover the loaded frame with the tent. Place the lighted blow-lamp in the pit so that the whole flame enters the pipe. Place the thermometer in position. Take the time when the thermometer registers 75° C. Twenty minutes of this temperature will kill lice and eggs. By working from 85° C.–90° C. the time can be shortened. When dealing with skins and leather 85° C. should be the maximum. It is useless to disinfest damp clothing, as the heat is all used up in drying. Watch the temperature and regulate by the cock on the blow-lamp. The burner of the lamp must be replaced by a more substantial one consisting of an iron ring with radially projecting internal pieces welded into position. The rings I am actually using are of 5/16th in. iron, 2 in. in diameter, with four projecting pieces of material somewhat thinner than the ring. The last requirement was a reliable insecticide which would be attractive to the natives. Nuttall, in *Parasitology*, Vol. X., No. 4, gives an exhaustive account of the action of most known insecticides, and I am familiar with his work. Previous to my own experiments paraffin had been relied on in an emulsion with soap. I found its insecticidal qualities disappointing; probably the pure paraffin one uses for burning is not so potent as crude kerosene. Not only was its action disappointing, but the natives did not like it.

To make a long story short, I found that a saturated solution of naphthalene in nut oil (about 1 in 8) was an efficient insecticide. Any oil will do, but the cheapest, as far as I know, is nut oil. This is now used to disinfest the head and body while the clothes are passing through the machine. Naphthalene oil is very attractive to the natives; strangely enough it has no objectionable smell, and it has a beneficial effect on scabies to which the natives are very prone. As far as my experience goes, naphthalene oil kills lice and nits on the hair of head and body. A gallon is sufficient for about 250 persons. The head acts as a sponge from which the body, specially the hairy parts, can be anointed when suitable opportunity arises.

The apparatus is a gradual evolution. Dr. J. A. Mitchell, the Secretary for Public Health; Dr. Park Ross, and myself of the Union Health Department, and Mr. Harries, of the magisterial staff have all participated in its development. Good experimental results have been obtained in Mr. Harries's district of 25,000 population, but reinfection readily takes place from surrounding districts. A campaign is now, however, being organised on a large scale, one apparatus in each district. To work the apparatus a white man is required with two native assistants. All are mounted, so the gang and apparatus are very mobile. Cases are found by the scouts in front, and the gang follows and rapidly de-verminises. Under old methods the natives concealed the disease. They had little incentive for reporting it, at the best a very unpleasant boiling and spoiling of their clothes, restriction of their movements, and no helpful treatment. The introduction of the rapid hot-air and naphthalene-oil method has changed all this. Far from concealing the disease, they now clamour for attention, and it is to be hoped that the scouts may be dispensed with in the near future.

As regards treatment, the native has a peculiar objection to drinking water when sick. If by advice this objection could be removed one would be going far towards mitigating the disease. The advice is always given, but I fear not always acted on.

ADDITIONAL NOTES ON THE IMMUNISING FUNCTION OF THE SUBEPITHELIAL LYMPHATIC GLANDS.

By KENELM H. DIGBY, M.B., B.S. LOND., F.R.C.S. ENG.,
HO TUNG PROFESSOR OF CLINICAL SURGERY AND PROFESSOR OF SURGERY IN THE UNIVERSITY OF HONG-KONG.

IN a series of papers from 1911 to 1917,[1] I developed the thesis that the tonsils, Peyer's patches, solitary lymph glands, and the vermiform appendix should be grouped together as the subepithelial lymphatic glands: that they were continually ingesting the adjacent bacteria in the nasal and alimentary channels by a process to which I gave the name phagotaxis; and that in all probability by this mechanism these subepithelial lymphatic glands were constantly immunising the body against various infections. In a book published in 1919[2] the available evidence was collected. Circumstances have prevented the carrying out of further direct experimentation. A few observations additional to those recorded in 1919 are, however, perhaps worth making.

First Suggestion of an Immunising Function for the Tonsil.

In 1919 I was unaware that the production of immunity had been definitely suggested as a function of any of the subepithelial lymphatic glands before 1911. R. H. Good, of Chicago, I now find from a reference given by Barnes,[3] wrote an article[4] in 1909 on Early Immunisation, the Essential Function of the Tonsil. Good, however, though aware of the passage of inert particles through the epithelium, believed that bacteria themselves did not pass. He therefore assumed that bacteria growing in the crypts of the tonsils produced their toxins which passed into the lymphoid tissue of the tonsil and provoked an immunising response. When sufficient opsonins had been formed the phagocytes emigrated into the crypts and attacked the bacteria, and the resulting mass was large enough to be squeezed out of the crypts and got rid of during the movements of swallowing. The words "lymph" and "vaccines" in Good's paper do not appear to be employed with their usual present meaning. There can be no doubt now that the lymphocytes of all the subepithelial lymphatic glands, including the tonsil, are continually throughout life emigrating through the overlying epithelium, engulfing bacteria, and returning through the epithelium into the lymphoid tissue, which is constantly crowded with bacteria in health. The theory of immunisation by the tonsils is thus in a far stronger position than was believed by Good.

Alimentary Immunisation.

That immunity against bacillary dysentery and Malta fever can be obtained by the oral administration of cultures has been shown by Nicolle and Conseil[5]; and work previous to 1919 on similar immunisation against typhoid fever has been repeatedly confirmed of late years.[6] Dead or living bacteria administered by the mouth will be taken up in large numbers by the lymphoid tissue of the tonsils, Peyer's patches, solitary glands, and vermiform appendix by the process of phagotaxis. And the further proof that has accumulated since 1919 of the successful vaccination by oral administration in various diseases is in support of the immunising function of the subepithelial lymphatic glands.

Healthily-acquired Immunity.

The recent brilliant researches of Dudley[7] have now supplied proof that mere exposure to diphtheritic infection without in any way suffering from the disease leads to the acquirement of immunity against the virus as shown by the Schick test. The virus almost certainly reaches the "contact" through the nose (directly or via the conjunctiva and lacrymonasal duct) or through the mouth. It is known that various mechanisms facilitate the rapid passage of the micro-organisms towards the naso-pharyngeal and faucial tonsils; and that when there they are engulfed by lymphocytes and carried wholesale into the lymphoid tissue in these glands. The conclusion is irresistible that these organs are concerned in this production of healthily-acquired immunity.

Further Work Indicated.

It is very desirable that researches on the lines initiated by Dudley should be carried out, to observe whether the acquirement of a Schick-negative reaction by exposure to diphtheritic infection is affected by previous complete tonsillectomy, both naso-pharyngeal and faucial. It would also be invaluable to know whether the morbidity and mortality rates of previously Schick-positive reactors on exposure to diphtheritic infection is influenced by previous complete naso-pharyngeal and faucial tonsillectomies. Indeed, the whole question of the response of the child deprived of most of its circum-pharyngeal ring of lymphoid tissue to the exanthemata would be a most useful subject for study in fever hospitals. Experimental work to test the vaccination power of the rabbit's appendix is contemplated, and this may also throw light on the work of the subepithelial lymphatic glands.

Evidence of Disease of Tonsils and Appendix.

But while there is room for much further investigation, it is, nevertheless, claimed that sufficient evidence has accumulated to call for the provisional acceptance of the view that the subepithelial lymphatic glands are the natural immunising organs of the body. This view is not popular, some surgeons regarding it as a reflection upon their work in removing tonsils and appendices. To admit that an organ has a useful function, however, does not imply that it should never be removed when it is the site of disease. The very function of vaccinating against infections renders the tonsils and appendix unusually liable to fierce assaults. The admission of a useful function does, however, demand that an organ should not be excised without adequate cause. The old fallacy that the human appendix is a vestigial relic was surely overthrown in 1919 by a study of the comparative anatomy and embryology[2]; yet it still continues to be taught and acted upon. Recently I saw a distinguished surgeon operate upon a woman of 25 for a ruptured extra-uterine gestation. After dealing most skilfully with the trouble he proceeded to remove a normal appendix. There was no history of appendicular trouble, but the surgeon justified himself by saying that appendicitis was a common and dangerous disease and without an appendix appendicitis was impossible. An acceptance of the theory of the immunising action of the appendix would positively contra-indicate such procedure.

Clinical indications for appendicectomy should be critically studied. In our present state of knowledge it may be worth while sometimes to remove the appendix as a remotely possible source of infection in some chronic systemic disease, but the culpability of the appendix is not at present proven. Appendicectomy for such conditions as epilepsy should be condemned. The diagnosis of chronic appendicitis for vague right-sided abdominal pain certainly requires searching analysis. As Haggard wrote in a recent editorial, "Chronic appendicitis is so easy to say and means so little. . . . We have little reason for diagnosing chronic appendicitis in the absence of acute or subacute attacks."[8] The diagnosis of chronic appendicitis has been strongly attacked by Hamilton Whiteford.[9]

Indications for Removal.

Again, if the tonsils have a useful function it is necessary to scrutinise critically the evidence that they are diseased before we remove them. Tonsils are removed either because of local lesions or on account of trouble elsewhere. With regard to local lesions moderate enlargement in childhood is no sign of disease. Enlargement of the naso-pharyngeal tonsil, however, may obstruct nasal respiration with serious consequences, and when it does so it always demands treatment. That whitish matter containing bacteria and phagocytes can be squeezed from the crypts cannot be accepted as a valid criterion of morbidity. Carruthers [10] has pointed out that such fluid can be squeezed out of the tonsils of healthy sheep and suggests that such fluid should be called "physiological pus." Certain it is that every healthy tonsillar crypt contains both phagocytes and bacteria.

Enlargement of glands in the upper part of the neck have doubtless often received their infection via the faucial tonsils; yet Kaiser[11] in his Effects of Tonsillectomy on the General Health of Five Thousand Children, states that whilst before operation 43 per cent. either had enlarged cervical glands or a history of enlarged glands, one year after operation 42 per cent. suffered from enlarged glands in the neck; for though some of the original enlargements had subsided, an additional 22 per cent. of the children had enlargement of glands previously normal.

With regard to systemic infections it is not sufficient to know that the virus entered by way of the tonsils. Whether infection takes place or not depends in large measure on the virulence and number of the organisms, and if invasion is to take place it is probably less serious via the tonsils than any other way. We must have reason for thinking that the tonsil has become a chronic focus from which reinvasion of the body is frequently occurring. There is some presumptive evidence that the tonsils may at times assume this rôle. And in selected cases it has been justifiable to enucleate the tonsils as a speculative operation in such chronic diseases as rheumatic fever and arthritis deformans. But the after-histories must be investigated with scrupulous care, and routine tonsillectomy for such conditions cannot be universally recommended till the statistical evidence is conclusive. Sluder, who writes temperately on the subject, gives a list of some 70 conditions outside the tonsil, for which, rightly or wrongly, tonsillectomy has been practised,[12] and others may be added. For such varied complaints as chronic skin disease, asthma, nephritis, goitre, muscular rheumatism, iridocyclitis, and epithelioma of the larynx has the tonsil been punished. Yet (if we exclude the undoubtedly serious effects of nasal obstruction due to enlarged naso-pharyngeal tonsil) of what lesion remote from the tonsils can it be said that the beneficial effects of tonsillectomy have been soundly established on a scientific basis? In the case of rheumatic fever and its manifestations the balance of evidence appears to incline against tonsillectomy.

Pathological Evidence.

If the clinical evidence of disease in the subepithelial lymphatic glands is sometimes unsatisfactory, the pathological evidence is not always above suspicion. A constant encounter is going on throughout life between bacteria and the lymphoid tissue of these glands. In consequence, the presence of intracellular bacteria in the lymph nodes and in the epithelium as well as on the surface, the collection of vast numbers of lymphocytes, and ultimately some degree of fibrosis are merely the expressions of the normal physiological activity. The presence of bacteria in a germinal centre without breach of the overlying epithelium, though accepted by Proetz,[12] is *not* evidence of follicular tonsillitis. One must also be sceptical of a histological report of chronic *interstitial* tonsillitis or appendicitis as evidence of disease, for these glands are normally in a condition indistinguishable from chronic low-grade inflammation. Ulcers of the epithelium or the presence of polymorphonuclear leucocytes are, however, good microscopical evidence of disease.

It is, however, not my object here to discuss the whole subject of the indications for operations on the subepithelial lymphatic glands. I wish to urge the probability of an immunising function for the tonsils and appendix, and in view of such probability to press for closer examination of some of the indications for operation.

FOUR CASES OF MASTOID DISEASE.

BY T. G. D. BONAR, M.B., B.S. LOND.,
SURGICAL ASSISTANT AND DEMONSTRATOR OF ANATOMY,
GUY'S HOSPITAL, S.E.

THE following case was diagnosed as one of acute mastoiditis, causing a septic meningitis.

CASE 1.—Female, aged 59, admitted on March 28th, 1922, in a comatose condition.

History.—Her husband stated that for 30 years she had been deaf in her left ear. On March 23rd, 1922, she complained of pain in her left ear, and on the following day there was a small amount of blood-stained thin fluid. Hot fomentations were applied, and the pain disappeared, whilst the accompanying vomiting ceased. On the 27th she felt practically well again, but at 10 o'clock that night the pain began again in her ear and also in the occipital egion. On the afternoon of the 28th she became unconscious.

Condition on Admission.—There appeared to be some nduration over the left mastoid process and pus was found n the meatus. No tympanic membrane was to be seen; he right ear was normal, pupils reacted to light and were qual, discs showed presence of optic neuritis. Reflexes: Knee-jerks present on right, not on left, and there was right plantar extensor movement. She was markedly pastic on the right side, but her left side appeared normal. ler other systems appeared normal on examination. ulse, 120; temp., 102° F.; resp., 30.

Diagnosis.—Mastoid disease, ? meningitis, ? cerebral bscess.

Operation.—Left mastoid explored and much pus found n antrum, with soft unhealthy bone separating antrum rom middle cranial fossa. Lateral sinus normal, but lying vell forward, partially encroaching on mastoid antrum. Bone destruction went at least 1½ inches behind sinus. The niddle fossa dura was bulging and was not pulsating; here was also granulation tissue on it. Dura painted with ure carbolic acid and incised; temporo-sphenoidal lobe xplored, but no pus discovered. Dura was then closed nd repainted with pure carbolic, and wound was closed, rainage being left at the lower angle. By lumbar puncture urbid cerebro-spinal fluid under pressure was obtained. Bacteriological report of cerebro-spinal fluid stated, "An rganism resembling pneumococcus was seen in direct film, ut no growth on culture after 72 hours' incubation at 7° C." The swab taken from the pus from the antrum grew *treptococcus longus.* The patient died the same night, ever having regained consciousness. Before death she ad Cheyne-Stokes respiration, and repeatedly vomited a arkish-coloured fluid.

Post-mortem Examination.—Granulations on dura in eighbourhood of wound. Meningitis well-marked, especially ver vertex and Sylvian fissures of brain, with a greenish-oloured pus. Ventricles dilated. No other abnormality.

The next case was one of chronic mastoiditis and uberculous meningitis.

CASE 2.—Male, aged 16, admitted March 29th, 1922, for eningitis. No history obtainable either from patient or is parents.

Condition on Admission.—Pulse, 60; temp., 98° F.; resp., 20. here was ? some tenderness over left mastoid and signs discharge from left ear. Patient very irritable and xamination extremely difficult. As far as could be made it there was no other abnormality. Strongly positive ernig's sign, knee-jerks present, plantar reflexes flexor. n anæsthetic was given for purposes of examination; ine normal on analysis was then obtained, lumbar puncure gave a clear fluid under pressure, and on examination the ears a bulging drumhead was found with a very small rforation through which a little pus was oozing. A yringotomy was then performed and much pus was tained.

Diagnosis.—Acute mastoiditis associated with meningitis.

Operation.—The mastoid was opened and large quantities pus and granulation tissue were found everywhere. nus normal; no granulations on mid fossa or posterior ssa dura, although the former was bulging.

On March 30th the boy was much better and could speak tionally, although the latent period was long. The report the cerebro-spinal fluid was: "White cells, 183 per c.mm.; th polymorphs and lymphocytes present. Protein, 18 per cent. Sugar absent. Suggests tuberculous mening-s as opposed to septic."

The boy's history was also now available: 14 days before mission he had returned home suffering from headache d vomiting, went to bed, and remained there till admis-n. Everything eaten was vomited and he complained of violent abdominal pain. On the 23rd he became delirious and had been so more or less till admission. From this one would have diagnosed a meningitis rather than an acute mastoid. The cerebro-spinal fluid analysis bore this out and suggested it to be of tuberculous type.

On April 1st the patient was comatose and lumbar puncture gave clear fluid under pressure. Bacteriological examination of this showed that "on direct examination there was an excess of lymphocytes and some blood. No micro-organism was detected, and culture remained sterile." On the 3rd patient was more comatose, pupils now widely dilated; examination of fundus of his eye showed "choked disc" with ? tuberculous nodules on the choroid (especially nasal side). Lumbar puncture gave fluid with roughly the same analysis as before; also there was a low percentage chloride. He died at 11 P.M. with a pulse of 160, temp. 102°, resp. 40 just before death.

Post-mortem Examination.—No evidence of direct spread of sepsis to brain from mastoid antrum. Lateral sinus on the side of operation not thrombosed. Membranes over base of brain more opaque, a gelatinous substance filling the interpeduncular space. Ventricles dilated. Large caseating gland at bifurcation of trachea. Miliary tubercles seen over both lobes of left lung. Small tuberculous glands bulging in wall of pulmonary artery. Branches of pulmonary vessels of left upper lobe found to pass through caseating areas in the lung. Right lung on section showed no tuberculous foci. Bacteriological examination of fluid from interpeduncular fossa showed presence of a few tubercle bacilli.

The third case was one of cerebral abscess following on mastoiditis.

CASE 3.—Male, aged 45, admitted on March 31st, 1922, for pains in the head, otorrhœa, and drowsiness. Patient had had otorrhœa for years.

History of Present Disease.—March 21st he returned home from work complaining of pains in right side of head and right ear. On the 24th his ear bled, but did not ease his pain, as it had done on previous occasions. On the 28th his headache became much worse, and on the 30th he vomited several times.

Condition on Admission.—Patient very drowsy, but answered questions. Lay on his right side, occasionally trying to get up out of bed. Headache right-sided only. Ear: Absence of drum and ossicles; a foul discharge present; there was no mastoid tenderness. Neck rigid, pupils reacted to light and were equal; no abnormality of ocular movements, no cranial-nerve lesion demonstrable; flexor plantar reflexes, abdominal reflexes present, hands gripped equally. Other systems normal.

Diagnosis.—? Cerebral abscess.

Operation.—Right mastoid was opened and pus under pressure evacuated. Lateral sinus normal, but granulations on dura of middle fossa; dura also thickened. Incision made into dura and temporo-sphenoidal lobe explored, but no pus obtained. Mastoid drained.

On April 1st patient much better and more normal mentally; headache much better. Sugar in urine; lumbar puncture showed a cloudy fluid. On analysis polymorphs were in large excess. Protein was 0·18 per cent. No reduction of Fehling's solution. Patient died half hour after lumbar puncture.

Post-mortem Examination.—Lungs full of blood and break down readily. Atheroma of abdominal aorta. Liver mottled. Kidneys granular. Brain shows good cerebellar cone; an abscess in right temporo-sphenoidal lobe. Meningitis at base, with a thick adherent opaque membrane.

The fourth case was one of acute mastoiditis, septicæmia, infective endocarditis, and cerebral embolus.

CASE 4.—Male, aged 6, admitted on April 6th, 1922, for drowsiness.

Previous History.—Patient had always been weak; tonsils removed 15 months before for sepsis.

History of Present Disease.—Three weeks before (March 14th) patient complained of pains in head. Both ears (particularly left) a few hours later began to discharge a thick yellow pus. He gradually became much worse. On the 21st he had a 15 minutes' shivering attack and looked cold and blue. On the 28th he had another similar attack. On April 3rd his ears both stopped discharging, and patient did not like to be disturbed.

Condition on Admission.—Patient drowsy, could not be roused. Eyes reacted a light, pupils equal. Right fundus showed reddening of disc; marked photophobia in left eye. Reflexes normal. There appeared to be tenderness over the left mastoid. There was a bilateral perforation of his tympanic membranes. Profuse discharge from left meatus. Pulse, 120; temp., 104·6° F.; resp., 40.

Diagnosis.—? Cerebral abscess following acute mastoiditis.

Operation.—Left mastoid opened and much necrosis of bone found; pus present, middle fossa dura and lateral sinus exposed; both normal in appearance, the sinus being free from granulations and pulsating. Wound drained. Nine hours after operation patient developed a right-sided hemiplegia affecting face, arm, and leg. Abdominal reflexes absent; a right extensor plantar reflex; patient more comatose.

Second Operation.—Patient was therefore re-operated on at once, and the wound was explored. Dura not now pulsating or bulging. An incision was made into the dura, and an excess of cerebro-spinal fluid was immediately evacuated. Temporo-sphenoidal lobe thoroughly well explored with an aspirating syringe, but no pus obtained. The next day, the 6th, patient's temperature rose to 106° and his pulse was not palpable. He died on the morning of the 7th. Pulse, ?; temp., 106·2°; resp., 62.

Post-mortem Examination.—Lungs showed patches of broncho-pneumonia. Heart showed presence of early vegetations on the mitral valve. Some petechial hæmorrhage on pericardium and on heart surface. Heart muscle pale and flabby. Staining of aorta and hæmorrhages in most organs. Brain macroscopically normal. No cerebral abscess.

Remarks.

These four cases seem to be of interest in that they exemplify conditions accompanying middle-ear disease fortunately rarely encountered. Cases 1 and 3 demonstrate that chronic otitis media, although causing trivial symptoms, may be potentially the most dangerous to life. Case 3 also shows that in spite of thorough exploration a temporo-sphenoidal abscess may be entirely missed and suggests that lumbar puncture in such a condition may lead to fatal results. The association of tuberculous meningitis coincident with mastoid disease, though rare, may give rise to great difficulty in diagnosis and treatment. Septicæmia is well recognised as a complication of acute mastoiditis.

A CASE OF
ANAPHYLACTIC SHOCK DUE TO ALIMENTARY ABSORPTION.

By J. M. CLEARKIN, M.B., B.Ch.,
B.A.O. Belf., D.P.H.,
MEDICAL OFFICER OF HEALTH, DUNGANSTOWN, CO. WICKLOW;
LATE RESIDENT MEDICAL OFFICER, CITY INFIRMARY, BELFAST.

The classical picture of anaphylactic shock, as seen in the guinea-pig, is described by Besredka as follows:—

> "Scarcely is the test injection terminated than the animal begins to struggle; it scratches its muzzle as if wanting to remove a foreign body. Its struggles become more and more marked; it commences to turn round and round and then to turn somersaults, which become more and more frequent and violent. Then the convulsive attacks begin to take place at greater intervals, and the animal, having become weakened from the output of so much energy, lies on its side. The vesical and anal sphincters are relaxed; there is involuntary discharge of urine and fæces. The respiratory movements, dyspnœic at first, become slower and slower, and finally become paralysed."[1]

A case of anaphylaxis, resulting from the absorption of milk from the alimentary canal, which I met with recently, in practice, is here recorded owing to its unusual character.

A girl aged 5 years, who had always previously been healthy, became ill on March 5th, the mother having remarked that she passed some blood with the motions. She was not aware of the child having had an attack of diarrhœa. The patient had been somewhat feverish, but had not vomited. The diet consisted, as was usual in the family, of potatoes, eggs, milk, tea, and bread. I was called to see her on the 7th.

Condition on Examination.—I found no abdominal resistance. The tongue was dry and slightly coated. The temperature and respiration were normal and the pulse was 80. There was no disease of the heart or lungs. I restricted the diet to milk, and prescribed bismuth carbonate 10 gr. three times a day. This diet was strictly adhered to throughout.

Course of Case.—Three days after the adoption of this régime the child passed a round worm (*Ascaris lumbricoides*) and thereafter the mother noticed her getting worse. Two days later I received an urgent message to come and see the child as she was extremely ill. The mother stated that the child was constantly "fighting and scratching her nose, gasping and stretching herself and sighing," and that she was always "falling away" if she tried to sit or stand up. During the previous few days there had been diarrhœa with blood-stained motions. The patient complained of some abdominal pain. There was no vomiting, but nausea was evident. The tongue was dry and red, pulse 110, temperature normal. The pupils were dilated. These symptoms had reached their culmination on this day. The mother was anxious to have the child removed to hospital.

I persuaded her to keep the child at home and ordered the milk to be boiled before use. I ceased the administration of bismuth. A change came about very rapidly as a result of this alteration in treatment. On the following day, the 14th, the patient was able to rest quietly in bed. The gasping and sighing and restlessness had gone, but she still had blood-stained diarrhœa. On the 15th the improvement continued and the diarrhœa was less; on the 16th the tongue was only slightly furred, temperature normal, there was no abdominal pain or nasal irritation, and she was out of bed; diarrhœa had ceased.

A scarification test with raw milk on the arm gave a reaction in half an hour. On the evening of the 16th the child was again given a drink of uncooked milk, and again complained of the irritation in her nose. After two weeks' avoidance of fresh milk she was once more able to take it without untoward effect.

Remarks.

The results obtained by boiling the milk are not suc as one would expect to find if the symptoms were du to protein sensitisation from milk, for Besredka state that the sensibiligen of milk is thermostable and wil withstand a temperature of 100° or 120° C. and i thereby perceptibly diminished in its toxicity.[2] Thi case is of interest as illustrating the fact first state by Richet at the International Medical Congress (1913 that "experimental alimentary anaphylaxis is difficult to bring about under conditions of healthy digestion, since it is a question of toxalbumins or nutritiv albumins, either because the digestive juices activel intervene in transforming these albumins and renderin them innocuous, or because the individual is immunise against them." Now in this family of a mother an five children, varying in age from 1 to 7 years, th substances going to make up the diet were the sam for all; the same milk was partaken of without an of the others manifesting gastric disturbance. But i the child whose case has been described a lesion havin been caused in the intestinal mucous membrane by worm, an area was left which was highly susceptibl to the absorption of foreign protein, such as would b conveyed by milk.

Intolerance of a milk diet is not unusual,[3] but train of symptoms so closely approximating to thos of anaphylactic shock, and passing off after the lesio in the bowel wall has had time to heal, is, I believ rare. One other possibility must be considered—viz that the bowels in the presence of a disturbance wer unable to carry the digestion of the milk to a suitab stage for its proper assimilation. The presence of a unusually permeable patch of bowel left the way ope for the absorption of toxic products whose digestio was completed in the tissues.[4] Such a contingency not so remote when one considers how frequentl persons become supersensitive to certain proteins aft intestinal operations. This hypersensitiveness ma pass off in months or in years according as th individual realises his inability to assimilate the foo in the same amounts as formerly.

It is worthy of note that the child has, since Marc been quite healthy and free from any complaint, an has never since passed any worms, although treate with santonin. Practically all the children of th district (Wicklow) are infected with worms, but I ha found none of them manifesting such a distincti group of symptoms as this one.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

CONSTIPATION FROM THE GENERAL PRACTITIONER'S POINT OF VIEW.

A MEETING of this Society was held at 11, Chandos-treet, Cavendish-square, W., on Nov. 12th, Dr. HERBERT SPENCER in the chair.

Dr. H. DES VŒUX introduced a discussion on this subject. He spoke of the unhappy experience, no doubt common to all medical men, of being consulted by an old friend, who thought he wanted a pill, as his bowels were not acting easily and his appetite had gone off a little—a patient whose general aspect was good, in whom an ordinary examination showed nothing until a finger introduced into the rectum discovered a large and irremovable mass. He conrasted this experience with the almost pleasurable eeling produced when another friend came to say hat he felt "very ill and all to pieces" and looked it, but on examination showed nothing but a loaded rectum, and perhaps a loaded colon, showing him to be merely suffering from the secondary effects of constipation amenable to a course of some laxative. This complacent exaltation was, however, unjustified, or no healthy friend of a practitioner ought to have been allowed to get into such a condition, at any rate f he had ever consulted the practitioner previously. This class of case, and others similar, were due to aulty medical teaching and would not be encountered so frequently had the consequences of bad habits been drilled into the minds of medical men when they were young. The profession should lay it down as a canon of sound and healthful existence that the bowels could and would act daily and naturally—that is, without medicament or extraneous help. There was too much of the attitude of mind of the physician who said when puzzled at a diagnosis, "Well, thank God we have the bowels to treat." When he was young it was taught that a daily evacuation was essential, and the unnatural corollary was that purgatives and laxatives were freely and thoughtlessly administered; this doctrine apparently still remained, hough perhaps it had been slightly modified. It certainly existed still in the nursery, where tender nfants were constantly dosed for any slight ailment; all were familiar with the parent who announced at he doctor's first visit, "Of course, I have given a dose of so-and-so." He often wished that the whole of his class of medicine could be scheduled amongst the dangerous drugs, for he felt convinced that in the long un more harm was produced by them than by morphia, cocaine, and the like. In practice about half the doctor's work was connected with the tomach and bowels; individual members of the proession had little power to prevent the occurrence of diseases of the heart and lungs, but they had ample means of preventing those of the stomach and bowels f they did but exercise them. The rectum and the bladder had much the same functions to perform under similar physiological management, but over he former came the interference of the conscious mind, while the latter was governed almost unconciously. The reflex action of the bladder, however, ould only be restrained for a short time, whereas he rectum could be controlled to suit convenience. The result was that the number of bladder trouble ases to be dealt with was infinitesimal compared with hat of troubles of the bowel. A healthy bowel meant a healthy body; the druggist's shop provided sop to Cerberus, which once thrown must be repeated at intervals.

Beginnings of Constipation in Infants.

In most infants the bowels began to act naturally, but once dosing had begun it was a labour of Sisyphus o stop it, for at sign of any bad temper, fit of crying, r slight ailment, down would go another dose. The evil of constipation thus began early in life; it was not until the age of 3 or 4 or even later that the fully developed symptoms of the disease attracted attention. The child was brought to the doctor because it was a bad feeder and sleeper, cranky and ill-tempered, thin, and anæmic; tonics of all sorts have been tried, digestive mixtures galore, and above all, plenty of nourishing food. This last item covered a great part of the trouble; such a case was easily and successfully treated by allowing three meals a day instead of the customary five or six (with extras). Some agreement as to what was meant by constipation was necessary; the simplest definition of the condition was "the retention in any part of the bowel of the unused or unusable food that has been ingested." Animals living a healthy life (which lap dogs did not) passed their excrement at such times and in such places as suited their convenience; in the human being the bringing of the defæcating reflex under the control of the conscious mind and not the upright position, as some would have them believe, first induced the constipated habit. He had learned by bitter experience that little or no useful information could be gained from the answers to questions concerning appetite, the amount eaten, and the action of the bowels; patients always lied about the amount they ate and were quite ignorant as to whether they passed a sufficient motion or not. A daily motion might be large or small, dry or soft; and the amount of it would depend on the bulk of food taken. It was absurd to be satisfied with the answer that there was a daily action. In the majority of cases, at all ages, the amount passed was probably not the totality of the content of the big bowel; there was probably always a residuum. In a normal bowel the sensation of fæces in the rectum was uncomfortable and led to evacuation, but the civilised bowel had been educated to neglect this feeling. If a patient could not diagnose his own constipation it became the doctor's duty to neglect the patient's opinion on the subject and decide for himself. Until the diagnosis of constipation was taught the disease would continue unabated. For some years, with a certain amount of success, he had been trying to diagnose the condition without X ray examination. If fæcal lumps were felt in the rectum or colon the patient was constipated; this diagnosis was often possible and not difficult provided the abdominal wall could be relaxed. He thought that a further step might be taken; if the colon, in part or in whole, was constantly distended the diagnosis was justified. Beyond these two signs he had not discovered any of use, apart from that series described by Sir Arbuthnot Lane.

Was there any connexion between constipation and the common and increasing conditions of adenoids, enlarged tonsils, and decay of the teeth? Would these common conditions become less frequent if constipation was prevented? He believed them to be close allies. Again, was proptosis ever congenital? It could be traced to very early life, and was due to overloading. If a child ate largely and from appetite all that was placed before it, it did not suffer permanently or even temporarily so long as the appetite was not unduly excited by a rich and tempting diet, and so long as the bowel emptied itself properly.

Dangers of "Feeding Up."

If food was taken by the dictates of Nature the latter would find means of disposing of it rightly; the only physical sign found was a slight distension of the stomach and some flatulence in the bowel. Far different was the result produced by the "feeding-up" process, where a child eating sparingly as Nature dictated caused alarm to anxious parents; then came the treatment considered necessary, and the more the child complained the more nourishment was given, together with a ferruginous or other tonic. Under the strain the intestinal organs became and remained bent, the abdominal fat was absorbed, and the whole contents of the abdomen progressed downwards towards the pelvis, although partially restrained in their course by artificial struts and ties and this terrible illness was established. The cause of all these later abdominal troubles was to be found in the baneful expressions "nourishing food," "digestible food," and "feeding up." Nature, without prompting, dictated in all healthy individuals the amount of nourishment required. The suckling child took the amount it wished; after the suckling period was past, we were told that "all food must be nourishing and digestible." Nature pointed out when the time came for a change of diet; why should we direct the contrary? All food ought to contain a considerable proportion of indigestible substances, for this part of the ingesta passed through from one end to the other and acted as a gentle stimulus. The contents of the colon ought to be indigestible and ought to be bulky, and they could not appear there unless they had been swallowed. But as much as possible of those things that are considered indigestible were rigidly and purposely excluded from the diet of young children, whereas the skins of fruits and vegetables—e.g., of apples and potatoes—the stalks of vegetables—e.g., cabbage—and the skins of animals ought in every case to be included. Young children were not allowed to eat hard food for fear of damage to their teeth, with the result that a child with strong undiseased teeth was rare. Further, as a result of want of use of the muscles of the mouth and jaw, the mouth and throat did not develop as they should, the throat became blocked with growth and nasal breathing was impeded. These children were constantly dosed; they became liable to feverish attacks, and for each attack they were dosed again. This was wrong, as was also the feeding of feverish patients —e.g., those with measles and pneumonia. No fevered patients required more than a minimum of food; even when it was forced on them they probably assimilated little of it. These attacks were ushered in with loss of appetite and with thirst; the patient's one demand was for drink—even inveterate smokers lost all taste for tobacco. As much drink as was demanded should be allowed. He knew of no greater comfort to a pneumonia patient than to restrict all nourishment to water, and had for many years followed this practice, of which one of the most gratifying results was that no laxatives were required. The tongue did not dry up, it cleaned rapidly, and the appetite returned with the disappearance of fever. A simple enema might be required to wash out the lower bowel, and need never be refused, for it gave great relief by encouraging the passage of flatulence, and no fear need be entertained of a habit being produced.

Diet for Adults.

In course of time the incidence of constipation and its consequences would tend to diminish; but this result can only come with the growing up of the present generation, and the doctor was left face to face with the problem of the adult population, with two alternatives—diet, and medical treatment by enemas or drugs assisted by massage and physical exercises. The best method was by diet; he believed that people could eat as much as they wished provided that the food passed through quickly enough, and that all residuum was cleared daily. Among suggestions for prevention of constipation, mention of the mind must not be omitted. One hundred years ago Dr. Reece recommended "bringing the mind to bear on the intestinal canal, peristaltic motion being easily retarded or increased by this medium." The body should be exercised daily; all systems of exercises had in common the drawback of taking up too much time, and the great majority of those who began them gave them up after a few weeks or months. To overcome this difficulty he had modified a few exercises taught him at school by the old drill sergeant. (The exercises were shown on the screen.) The advantages claimed for these exercises were that (1) they occupied a very short time (1½ to 3 minutes); (2) they were suitable for young and old; (3) they worked every joint in the body; (4) they called especially for frequent and deep respiration; and (5) the heart had to put out its best to carry them through.

Discussion.

Dr. **Walter Broadbent** said he agreed with practically everything Dr. Des Vœux had put forward. He thought skipping might take the place of the exercises shown on the film. Peristalsis in the colon differed from peristalsis in the small intestine in that it occurred in mass form, and only four or five times a day, being occasioned by the ingestion of meals and by defæcation. Gastric and duodenal ulcers, among other factors, delayed food and prevented dilatation of the ileo-cæcal valve, thereby causing stasis. Undue motility of the ascending colon also caused stasis. He did not believe in the part said to be played by kinks; many people had kinks who had not constipation; 75 per cent. of constipation was due to loss of sensitiveness and distension of the upper rectum as a result of neglect or inhibition of the impulse to defæcate. Constipation often arose in infancy as a result of carelessness on the part of mother or nurse. Babies should be encouraged to defæcate every day, soon after a feed. When older they should not be allowed to go out to play after breakfast until they had had an action of the bowels. A few years ago a difference was to be noted between the sexes with regard to constipation; the latter was found more frequently among females. The more hygienic modern corset, the better provision of water-closets in girls' schools, and probably increased athleticism among girls, had benefited the latter. X ray examination was valuable for accurate treatment, but was expensive. The early morning cup of tea and a glass of hot water at night were useful, together with fruit at beginning of breakfast and at other times during the day, figs and rhubarb being the best. Stasis frequently began at the sigmoid, and treatment should be started at that end. The best form of treatment was with glycerine suppositories, or with enemata given for three days running after breakfast. If these failed, recourse must be had to drugs, among which he rated salts low.

Dr. D. M. **Barcroft** said that constipation was not a disease but a symptom, and a symptom not of any great value from a diagnostic standpoint, as it figured in the picture of the great majority of described diseases. The fact that a patient confined to bed was unable satisfactorily to evacuate the bowels with a bed-pan showed that posture was a factor in proper defæcation; posture might, therefore, be equally a factor in the prevention of mild constipation. As Prof. John Chiene, of Edinburgh, used frequently to point out, the most satisfactory posture was with the thighs acutely flexed. Defæcation was a combination of voluntary and involuntary mechanism, and was also the terminal fact in a series of involuntary muscular efforts and in the elaborate chemical process of digestion. The process of evacuation of waste material, like the process of the taking of meals, should be regular; but it was impossible to speak dogmatically as regards intervals of time. The patient should try to establish a habit that the evacuation should be at approximately the same time every day. Passing on to treatment, the multitude of quack medicines made it unusual for a doctor to be consulted about constipation unless the latter were severe. It was possible to form an idea of the wide variations of the normal conditions of the bowels. In constipation there was often a big element of muscular overstretching and fatigue, in view of which the forcing of muscular contraction with cathartics and the employment of large enemata were equally harmful.

Dr. W. W. **Stocker** agreed that constipation was a symptom, not a disease. In abnormal cases evacuation of the bowels might be retarded for months. Auto-intoxication, diagnosed by the patients themselves led them to take purgatives, with the result that a vicious circle was set up. Real fæcal sapræmia sometimes occurred, or fæcal tumours which had to be carefully distinguished from malignant growths. In young women the swollen colon pressing on the uterus might cause intense pain. Sedentary habits and laziness gave rise to constipation; the modern lavatory at was too high and anatomically incorrect, giving se to a mechanical difficulty. Prevention was all-nportant in treatment. Aperients should not be sed; a normal saline draught, one quart in the orning, would act as a high enema and clear the nall intestine first. Lubrication was necessary and rganotherapy useful.

Dr. E. P. **FURBER** described the commencement of nstipation in infancy, when the child was frequently olded with regard to defæcation and otherwise taught regard the act as unpleasant. Other causes were ulty diet, pathological conditions such as a grumbling ppendix, visceroptosis, a painful anus resulting in ar of the act, and damage to the pelvic floor. He owed an American colon douche, known as Till's scade, which he had found useful.

Dr. P. B. **SPURGIN** defined constipation as not only packing together of the intestinal contents, but as n inability to evacuate a quantity of fæcal debris orresponding to the amount of solid food taken—a abit due to various causes. Children developed this abit through being encouraged by mother or nurse to ut the act off; some children were also very obstinate, nd lack of perseverance on the mother's part led to e habit. He also referred to the misuse of aperients nd to the harm done by the weakness resulting from ver-exercise of a child's muscles. Irregularity of the our of defæcation was natural in a very young child, ut in an older child should be discouraged. He eplored the habit of many adults of dosing themselves ith aspirin to remove the headache that accompanied nstipation.

Dr. H. **MORELAND McCREA** believed that the causes f constipation varied in the differing decades of life. n the first decade of childhood, after the period of fancy, laziness was the main cause, and the sexes ere equally affected. In the second decade it grew ommoner in females, chiefly because of shyness and f the still existing insufficiency of lavatories in girls' chools. In the third decade women still led, as pelvic isorder began to tell. In the fourth decade males ere beginning to lose their advantage; the commonest ause of constipation in women at this age was the ss of muscle power in multiparæ. From the ages of 0 to 50 the sexes were again about equal. Hypo-hyroidism of the menopause now became a factor. s regards treatment, diet was important; it was hard o make the mother understand what harm was done y milk in the causing of constipation. The time ould finally come for the use of drugs; and drugs urrying through the small intestine did not benefit he patient. The obstruction should be found with rays; if it was higher than the cæcum no purgatives hould be given. He found cascara the most useful rug.

Dr. **SPENCER** closed the discussion and Dr. **DES ŒUX** briefly replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

A MEETING of this section was held in the Royal ollege of Physicians of Ireland on Nov. 2nd, Dr. OSEPH T. WIGHAM, the President, being in the hair.

Dr. W. D. **O'KELLY** demonstrated

A New Method of Making Museum Jars.

e pointed out that in connexion with glass jars here were certain difficulties. It was hard to get hem the size to fit all specimens, and it was also ard to store them, as being made of glass they were rittle and very easily broken. He now made his wn jars of celluloid. By doing this he was able to et the jars any size he required.—The **PRESIDENT** aid that the method was one by which it was possible o economise weight, fluid, and expense, and also the rs really showed off the specimens they contained o better advantage than did glass jars.

Dr. A. R. **PARSONS** described a case of early Hanot's disease, with specimens prepared by Dr. A. C. O'Sullivan.

Dr. **GEOFFREY HARVEY** and the **PRESIDENT** followed with a case of splenic atrophy with thrombosis of the splenic artery.

Dr. H. C. C. **DEANE** contributed

An Unusual Case of Tubal Pregnancy.

The patient was admitted to the Royal City of Dublin Hospital on August 11th, 1923, complaining of abdominal pain. She was 38 years of age, married ten years, had three childred aged 8, 6, and 3 years, all alive and healthy. She had had no abortions, miscarriages, or premature births. Since the birth of her last child her periods had never been regular. Sometimes complete amenorrhœa occurred for three or four months at a time. She complained of constipation, otherwise she was in good health. The first attack of abdominal pain occurred about ten days before admission to hospital. The pain came on suddenly, and was confined to the lower abdomen, being more marked on the left side. The pain passed off gradually, and in two days' time she was up and about apparently as well as ever. A week later she had another attack which was similar to the previous one, but was more severe and accompanied by dry retching. The following day the patient was admitted to hospital. On examination she looked well, pulse and temperature normal. There was tenderness but no rigidity over lower abdomen. Otherwise examination was negative. There was a history of three months' amenorrhœa. Three hours after admission she got a severe attack of abdominal pain accompanied by dry retching. On being examined again the patient was pale, temperature subnormal, and pulse rapid and almost imperceptible. The lower abdomen was tender and rigid. There was no dullness or distension and no abdominal respiration. Rectal examination revealed a boggy mass filling up the pouch of Douglas. There was no blood in the vagina.

She was operated on at once. As soon as the peritoneum was divided an abundant escape of blood and clot occurred. The lower part of the abdominal cavity and the pelvis was filled with blood and clot. The Fallopian tube on the left side was identified. A loop of intestine was adherent to the tube and broad ligament. The intestine was freed, and a tumour about the size of a walnut was revealed midway between the uterus and the infundibulum. This tumour presented on its upper surface an opening with ragged edges from which blood was oozing. The tube was removed and the abdomen closed. A few days after the operation a uterine cast was expelled. Both this cast and the tube were sent to Dr. E. C. Smith for examination. She was discharged from hospital 25 days later, and is still alive and well.

In describing the tumour, Dr. **SMITH** said that on naked-eye examination it was found to be composed of dark-coloured friable tissue, very like blood-clot. It was covered in part by a shiny smooth membrane. Numerous blocks were taken and paraffin sections made. In most of these chorionic villi were present, they were very irregular in size, some looking like those seen in a hydatid mole. The arrangement of the covering cells was rather atypical. Islands and strands of syncytium were abundant, and also irregular groups of Langhans's cells. In some of the sections the tube wall was seen to be infiltrated by the fœtal cells, small syncytial masses were lying between the muscle fibres of the wall. He was doubtful as to whether the condition should be regarded as a simple tubal pregnancy or one tending to become a chorion epithelioma. Another point which he thought was of interest was the formation of well-marked decidual cells around the vessels as could be seen in the sections. The uterine cast was found to be composed of poorly formed decidua, as is usual in cases of extra-uterine gestation. It was degenerated and hæmorrhagic in parts.

In the discussion which followed Dr. T. T. **O'FARRELL** remarked that this condition was sometimes believed to follow gonorrhœa.—Dr. R. J. **ROWLETTE** said that as it was three months since the operation, and as the patient was now quite well, malignancy of the tumour was out of the question.

Dr. T. O. **GRAHAM** described a case of

Intrathoracic Sarcoma.

The patient, male, a labourer by trade, aged 39, came to the Eye and Ear Hospital complaining of difficulty in swallowing and breathing. He was somewhat hoarse, and had a very bad cough. At first it was thought he might be suffering from aneurysm of the aorta. He was slightly cyanosed, the veins were distended, and he was very short of breath. On percussion an area of dullness was found over about two-thirds of the chest. He was transferred to the Royal City of Dublin Hospital, and was recommended to the Coombe Hospital for treatment by the Erlangen method. The night before he was to go for treatment, however, his condition became serious, and after intense dyspnœa, lasting about seven minutes, he died.

Dr. A. C. O'SULLIVAN in describing the specimen said that the tumour was rather soft, and very hæmorrhagic. The growth extended into the glands on the right side of the neck, and it also descended as far as the pericardium. The heart, lungs, and the lower portion of the pericardium were completely free. There had not been infection of the abdominal glands, but the glands behind the stomach and the pancreas were affected. The spleen was rather enlarged, but not infected at all. The cells were very regular and small, just a little larger than lymphoid cells, but not the large cells which were generally seen in lympho-sarcoma.—The PRESIDENT asked whether the difficulty in breathing in this case was due to the size of the tumour, or was caused by nerve involvement.—Dr PARSONS said that in most cases of internal sarcoma he thought that difficulty of swallowing was not a symptom. When the patient came into hospital he said that he had had these symptoms for two months. There were large glands in the axilla, but no pleural effusion whatsoever.

Reviews and Notices of Books.

BÉCHAMP OR PASTEUR?

By E. DOUGLAS HUME. Founded upon MS. by MONTAGU R. LEVERSON. London: Simpkin, Marshall, Hamilton, Kent and Co.; Chicago: Covici-McGee. 1923. Pp. 296. 6*s*.

Pierre Jacques Antoine Béchamp was born in Lorraine in 1816. He was educated as a pharmacist, was professor successively at Strasbourg, Montpellier, and Lille, and died in Paris in 1908. Most of his long and vigorous life was occupied with the establishment of his doctrine of microzymas. It is not altogether easy to make out what this was from the present account, which is put together by the author of "The Multiplicities of Una" from materials accumulated by an enthusiastic admirer of Béchamp. But it seems that microzymas are intracellular molecular granulations which are, like Altmann's granules and the micellæ of some recent French authors, the fundamental units of living matter. They produce ferments, are responsible for the functional activities of tissues, and are physiologically indestructible. They may develop into bacteria, which are the result and not the cause of disease, either inside or outside the body; thus the putrefaction of a corpse is due to the microzymas which built it up changing their form and function after death; and the bacilli in the blood in anthrax are developmental forms of elements of the animal's own tissues. Shortly, then, Béchamp's point was that germs were not pre-existent independent organisms; Pasteur said they were: both objected to spontaneous generation.

There is probably much that is of interest in the abundant writings of Béchamp; a list is given at the end of the book. And if anyone wants to judge how far he anticipated Pasteur in some of his views, and which of them barked up the right tree when they found themselves in the same wood, he must go to these originals. In the Hume-Leverson summary Béchamp is the injured and saintly hero, Pasteur the successful villain; it is a version no one can wholly believe. Pasteur no doubt had an eye on his career, and he was apt to be rather short with people who differed from him; Béchamp surely made some mistakes, perhaps a good many. But they both did their best in the pursuit of natural knowledge; they are on the same side in that at any rate.

CANCER.

The Increasing Plague of the Century. An address delivered in the first instance to Sisters and Nurses of the London Homœopathic Hospital; later revised and amplified by GEORGE BURFORD, M.B., C.M., Senior Consulting Physician to the London Homœopathic Hospital. London: John Bale, Sons and Danielsson. 1923. 3*s*. 6*d*.

THE fact that the nursing profession stands as an intermediary between the doctors and the public has prompted Dr. Burford to address sisters and nurses in rather exalted prose and occasional verse on the subject of cancer, which he prefers to call malignancy. His views as to the prevalence, criteria, spread, and therapeutics of malignant growths are in the main orthodox, the differences from accepted opinion being chiefly his claim that emotional stress is a factor predisposing to malignant neoplasms and his emphasis on the connexion between an accidental injury and subsequent development of cancer. There is, indeed, little room for coincidence in Dr. Burford's philosophy. For example, under the heading of the Scope and Warrant of Surgery in Cancer, he states that where removal is impracticable, exploratory invasion into the abdomen alone is on occasion followed by spontaneous complete absorption of the neoplasm. For the rest, the matter in Dr. Burford's address is better than its presentation. Throughout he prefers the abstract to the concrete, the involved sentence to the simple case, the long to the short word. This is not a mere lapse of taste but a serious drawback to a book designed to promote and maintain a sane outlook on malignant disease. Nurses as a class are apt to think and speak in italics, and an attempt to educate them to help their afflicted patients to understand and others to avert malignant disease should emphasise mainly the duty of avoiding panic while seeking advice. The point that pain is not an early symptom of cancer is one of those which are not sufficiently brought out by Dr. Burford, and indeed, on comparing his expanded lecture with the recently published pamphlet of the Ministry of Health, there is but little doubt which would be more acceptable and informative to the average nurse.

A MIND THAT FOUND ITSELF.

By CLIFFORD WHITTINGHAM BEERS. London: William Heinemann. 1923. Pp. 411. 7*s*. 6*d*.

THE present edition of this work appears to differ in no respect from that reviewed in these columns about a year ago, except in the fact that it has found a London publisher. Since its original publication in 1907 the narrative has, of course, undergone much revision, chiefly in the direction of excluding mere propaganda, much of which, thanks to changes due largely to the author's own influence, is now irrelevant. In fact, the original purpose of the book has been achieved in America, and it has taken its place rather as a classic in the literature of psychiatry. No other such account as this of an attack of insanity has ever been written; the combination of exact memory, literary ability, and quite unusual powers of introspection and self-analysis must be sufficiently rare in potential authors of this kind to render it quite improbable that this example will be equalled in the future. Perhaps its most remarkable chapter is that which describes the early hallucinations of the author's malady, and the features in his environment on the misinterpretation of which a system of delusions was built. This process is traced in considerable detail and illustrates vividly the ease with which a small error in management, such as a careless word from the physician or attendant, may give rise to a new delusion.

It is perhaps not true to say that the book's purpose fulfilled. Its chief lesson is the dependence of the atient on the sympathy of the nurse—the sympathy nd consideration which certainly appear to have een lacking in the attendants who had charge of ıe author at certain periods of his illness. However erfect the administration of an asylum, the type of ursing which is something more than merely ficient will always require an amount of patience ıd self-devotion which is not exercised without ffort, and it will always be the purpose of this book point to the necessity for such effort, and its ıpreme value to the patient whose chief trouble is ıat he is without a friend. Mr. Beers has devoted is subsequent life to bettering the condition of the ısane in the United States, and it is fortunate for ıem that his malady has not recurred. He recently isited this country, where many members of the ledico-Psychological Association had the pleasure of ıeeting him.

IINOR MALADIES AND THEIR TREATMENT.

Fifth edition. By LEONARD WILLIAMS, M.D., Physician to the French Hospital. London: Baillière, Tindall and Cox. 1923. Pp. 414. 7*s*. 6*d*.

THE enthusiasm of youth, the experience of age, ombined with the ready use of a fluent pen, make the ew edition of this well-known book an instructive uide and comforter to the practitioner of medicine, e he young or old. It is full of useful information ained from the practice of one who is a careful bserver of all he sees, and who evidently delights ı meticulous analysis and loves tabulation. The hapters run on from one subject of common interest to nother, and give a vivid account of illness as it resents itself in the consulting and sick room. The eader cannot be dull for one moment while reading he circumstantial narration of those complaints with hich he is most familiar, for whatever may be his revious knowledge, he will be certain to find some riginal thought and suggestion either in diagnosis or reatment. Whether he will be inclined to follow all he arguments of the author—for example, those hereby he conclusively separates such diseases as heumatism and "goutiness"—is another matter, and hether he will find all treatment as successful as)r. Williams seems to suggest is open to question. But he cannot fail to learn much from this little ook that is useful in practice.

NFECTIVE DISEASES.

Die Experimentelle Bakteriologie und die Infektionskrankheiten, mit besonderer Berücksichtigung der Immunitätslehre. By Dr. W. KOLLE, Direktor des Institutes für Experimentelle Therapie, o. Honorarprofessor an der Universität Frankfurt a. Main; und Dr. H. HETSCH, Professor, Generaloberarzt und Mitglied des Institutes für Experimentelle Therapie in Frankfurt a. Main. Berlin and Vienna: Urban and Schwarzenberg. Pp. 1376.

THIS is a treatise upon the whole aspect of infective liseases, touching upon their clinical manifestations, liagnosis, pathology, and experimental investigation; t also deals with such animal infections as are of mportance in relationship to the study of human lisease. Of necessity a work of this scale must e largely a compilation; this is admirably put ogether. It is a type of book which is at present nuch wanted in the English language. In works on nedicine, in this country, we have nothing which so fficiently and broadly bridges the gap between the aboratory worker and the clinician. The latter is too ften content with methods which have had a long nd honourable past, but which can be adapted and mproved upon only if full knowledge of scientific nedicine be added to them. The laboratory worker, n the other hand, although he possesses an acquaintance with the more intimate workings of disease processes is, as a general rule, debarred from any active contact with cases of disease. There are thus few men who have the knowledge or the opportunity to produce such a work.

We recommend the book to all physicians who desire to know what has been done and can be done in the investigation of infective diseases.

MEDICAL AXIOMS, APHORISMS, AND CLINICAL MEMORANDA.

Second impression. By JAMES ALEXANDER LINDSAY, M.A., M.D., F.R.C.P. London: H. K. Lewis. 1923. Pp. 194. 6*s*.

THIS is an excellent little book, one which would have delighted the late Samuel Gee, and we can give it no higher praise. Dr. Lindsay is well known as professor of medicine in the Queen's University of Belfast and as a valued teacher in the medical school of the same University. The first chapter alone of the book contains a mine of information—e.g., 53: "Think of common diseases first." Some wise physician has said: "The young physician generally thinks first of an obscure disease and the old one of a common one, and both are occasionally wrong." But we agree with Dr. Lindsay that the safer way is to think of the common disease first. Again, take aphorism 60, a saying of Sir Dominic Corrigan: "The trouble with most doctors is, not that they don't *know* enough, but that they don't *see* enough." Too many of us *look* without seeing. The clinical memoranda are admirable. In the section on anæmia (p. 165) we rather question whether memorandum 94 is not a little too wide: "An anæmia which does not yield to iron is not chlorosis, provided sufficient rest and suitable diet are secured." Here are two aphorisms which may be taken together. The first on p. 6: "Few studies are more instructive, more full of warning, or more generally neglected than the study of the history of medicine." And the second on p. 160: "In the treatment of renal dropsy common salt should be excluded from the dietary." This treatment, applied it is true to dropsy in general, was laid down by John of Gaddesden in the Rosa Medicinæ, circa 1314. On the whole we can imagine no more useful book for practitioners of all ages.

EXAMINATION OF THE ORGANS OF SENSE.

Handbuch der biologischen Arbeitsmethoden. Vol. V.: Methods of Study of the Functions of Individual Organs of the Animal Organism. Part 7, Section 3, No. 105. Edited by Prof. Dr. EMIL ABDERHALDEN, Director of the Physiological Institute of the University of Halle. Berlin and Vienna: Urban and Schwarzenberg. 1923. Pp. 330. Fr. (Swiss) 13·5.

THIS is part of a large series of publications on physiological methods of experimental examination, and deals with subjects of very unequal medical interest. The first article, by Jakob Katzenstein, on the methods of exploring the mode of action of the larynx for voice and speech, gives a full historical description of methods of examination from Garcia's first use of the laryngeal mirror, and describes the application to the examination of the movements of the vocal cords of the stroboscope, an instrument designed in 1834 for the study of vibrating membranes. Photography and kinematography of the larynx are also discussed. Numerous experiments on the cerebral centres for speech are next described, and methods of measuring tone and volume of sound duly recorded, as also are methods of measuring the movements of the lips and palate in speech. The article occupies nearly half the volume and is a monument of industry and learning invaluable to the research worker in this field. H. Zwaardemaker contributes articles on examination of taste and smell; Adolf Basler on examination of skin sensation, tactile, thermal, and painful; and, finally, Karl Schaefer describes examination methods on the physiological conduction of sound from the air to the internal ear, including investigation of the effect of the auricle and meatus on the conduction of sound waves, and of the movements of the drum-membrane and ossicles to sound vibrations. The work is devoted to the description of methods and gives little or no account of the results obtained, and is therefore of more value to the research worker than of interest to the medical practitioner.

ATOMIC FORM.

With Special Reference to the Configuration of the Carbon Atom. By EDWARD E. PRICE. London: Longmans, Green and Co. 1922. Pp. 148. 5*s.*

IN any considerations affecting the constitution of the atom the phenomenon of crystallisation must have an important place, and it is fair to state that no theories of atomic or molecular constitution which ignore the facts connected with the crystallisation of the elements can be considered as resting on a sound basis. Whilst the constitution of the atom is the subject of physical theories widely separated from the ideas set forth in the present volume it must be admitted that the author marshals his arguments in a clear and concise manner. Some readers who could not accept the theory of atomic form as described will probably find the models of aggregates of the carbonoid an assistance when considering some of the problems of organic chemistry—by enabling them more easily to visualise the structures in three dimensions.

AROMATICS AND THE SOUL.

By DAN MCKENZIE, M.D. Glasg. London: William Heinemann. 1923. Pp. 164. 7*s.* 6*d.*

THE physiology of smell is but very imperfectly understood and smells themselves are curious things (if we may call a smell a thing). Dr. McKenzie refers at some length to the manner in which smells can call up incidents long gone by. It is significant how close is the anatomical connexion between the olfactory lobes and the frontal cortex; even reading about smells will recall the past. Anyone who has travelled in the East must certainly have been conscious of smells when there, and we know a medical man who travelled some 40 years ago in out-of-the-way parts of the East, who tells us that he can never read Kipling's "Miracle of Purun Bhagat" without an immediate mental vision of an Eastern road.

Dr. McKenzie discourses pleasantly about the sense of smell in insects, birds, and animals. There is some doubt as to whether the power which the males of certain moths—e.g., the Great Peacock of Europe and the allied Emperor moth of England—possess of finding their way to a female is really dependent upon smell—i.e., the reception of some material substance or upon some hitherto unexplained wave motion, as Fabre suggests. As regards vultures and other carrion-feeding birds, we may supplement Dr. McKenzie's remarks on p. 85 with a reference to Waterton's amusing essay on "The Faculty of Scent in the Vulture," and the two following essays.

This is an interesting book, if somewhat sketchily written, and the subject is one that deserves further inquiry.

ABDOMINAL SURGERY FOR NURSES.

Second edition. By HAROLD BURROWS, F.R.C.S., Assistant Surgeon, Royal Portsmouth Hospital. London: The Scientific Press. 1923. Pp. 144. 4*s.*

THOUGH this second edition has been enlarged as compared with the first, the author has still contrived to compress within a small space much valuable information as to the "why and wherefore" of many of the points peculiar to the nursing of cases that come to abdominal operation, both in their preparation and in their after-care. In writing a book for nurses a medical man aims to impart such information as will render a nurse's work more interesting and so to secure her intelligent coöperation. To achieve this end the terms used should always be the simplest; in this respect Mr. Burrows has, in spite of obvious care, been occasionally indiscreet. In a future edition the final chapter on feeding might with advantage be enlarged beyond the two pages that are at present devoted to this important part of a nurse's duties.

NUTRITION OF MOTHER AND CHILD.

By C. ULYSSES MOORE, M.D., M.Sc. (Ped.), Instructor in Diseases of Children, University of Oregon Medical School, Medical Director of the Coöperative Infant Welfare Society of Oregon. London and Philadelphia: J. B. Lippincott Co. Pp. 234. $2.

FOR English readers the value of this book is diminished by the fact that a large number of the recipes for foods are not practicable outside the United States. We regret this, because the book as a whole is eminently readable, and the author has given an account of recent advances in our knowledge of dietetics which is both accurate and readily comprehensible. The numerous illustrations are appropriate for the purpose of emphasising the importance of breast-feeding and sound dietetics. The volume fulfils its purpose, and is a useful text-book for the young American mother.

CHEMISTRY.

Bloxam's Chemistry: Inorganic and Organic. Eleventh edition. Edited by A. G. BLOXAM, F.I.C., and S. J. LEWIS, D.Sc., F.I.C. London: J. and A. Churchill. 1923. Pp. 832. 36*s.*

THIS well-known work has survived ten editions, the first appearing as far back as 1867. In these days it is difficult to compress a survey of so wide a field as inorganic and organic chemistry into a single volume, and the editors state that the present form of the work has necessitated a greater condensation than they could wish. The grouping of aliphatic and aromatic compounds will no doubt be criticised in academic circles, but there is much to be said for it from the educational standpoint, since substances of the same order in the two great divisions are brought together. Space has been found for short accounts of present views on the structure of the atom, the quantum theory, crystal structure, &c., whilst, as might be expected when so well-known an expert as Dr. S. J. Lewis is joint editor, the subject he has made so peculiarly his own—viz., spectroscopy—has been rewritten and expanded.

We are impressed with the simplicity of the volume and with its accuracy. It is essentially a text-book for the student.

JOURNALS.

THE JOURNAL OF OBSTETRICS AND GYNÆCOLOGY OF THE BRITISH EMPIRE (Vol. XXX., No. 3).—The current autumn number of this journal maintains the standard established by its predecessors, and justifies the statement that the magazine now holds a position second to none in the obstetrical and gynæcological world.—Mr. Comyns Berkeley, in a brief editorial note, points out that the journal was first published in 1902, being founded by a number of leading obstetricians and gynæcologists not with the object of pecuniary profit, but with the patriotic intention of having a journal which should be a credit to the science, and which should provide a complete and impartial record of British work. Since its inception the journal has, in fact, continued to be financed from motives of public spirit, and Mr. Berkeley issues a stimulating appeal to the younger generation of obstetricians and gynæcologists to shoulder in their turn the burden so long borne by their seniors. From the excellence of the publication, apart from purely patriotic motives, we venture to hope that this appeal will not be neglected.—In the present issue Mr. Victor Bonney contributes a practical aper upon the pathology and treatment of certain ses of spasmodic diurnal incontinence of urine in omen. He points out that its occurrence is practically limited to women who have borne children, and at the cause lies in laxity of the anterior portion of e pubo-cervical muscle sheet.—The subject of erations on the round ligaments for the cure of ckward displacement of the uterus is discussed by r. Haig Fergusson, who criticises the present vogue r the Gilliam and Baldy-Webster technique, and escribes a modification of the Alexander-Adams eration. In his opinion this operation as modified free from the disabilities introduced by the former ethods, and removes the main objection to the assical Alexander-Adams operation—viz., the stigma working with inadequate knowledge of the con- tions in the pelvis.—An interesting study of the istological appearances of the wall of the pregnant terus at term in the case of the lesser mammals ppears from the pen of Prof. Keiffer, of Brussels. ections of the uterus, stained by the silver method Ramon y Cajal, demonstrate a very elaborate stem of ganglia and nerve axis cylinders extending om the mesometrium through the two muscular rata to the mucous layer. This paper throws much ew light upon the complex problem of uterine nervation.—Dr. Norman Cruikshank, working on ehalf of the Medical Research Council, describes a se of suppression of urine with symmetrical necrosis the renal cortex in a parturient woman. The ecrosis was apparently the result of thrombosis of e finer arterioles, the latter due to vascular spasm nd induced presumably by the action of an eclamptic xin.—Ante-natal physiology and pathology receives ttention in a paper by Drs. Lucas Keene and Evelyn ewer, upon the results of an investigation into the lative weights of fœtal organs at various stages of evelopment. These authors find that there is a efinite slowing down of the rate of increase in eight both of the fœtus and its organs between he thirty-third and thirty-ninth weeks of gestation. hey suggest that at this time metabolism is directed wards the laying down of fat, to the detriment of itrogen retention. Attention is drawn to the fact hat this period coincides with the rise in the urea ontent of the maternal blood, and that a failure in aternal nitrogen adjustment may account for the equency of eclampsia at this epoch.—An article of onsiderable general and practical interest is that of r. John Hewitt on bacterial infection of the urinary ract complicating pregnancy and the puerperium. his author agrees with Leith Murray's statement hat "in the absence of pus there is no real patho- gical significance in the demonstration of coliform rganisms in female urines." He further finds that he most accurate laboratory indication of pyelitis is he presence of pus cells and organisms in a single esh drop of uncentrifuged urine. The centrifuge in his connexion is unnecessary and misleading—a fact f some importance to the general practitioner.—r. Berkeley republishes in convenient form his nportant opening paper on the use and abuse of bstetric forceps from the Section of Obstetrics and ynæcology, British Medical Association meeting, 923. To this reference has previously been made. e also describes a convenient and simple form of ulval retractor designed for operations on the erineum and posterior vaginal walls when assistance not available.—Other contributions include papers n diffuse endometromyoma of the pregnant uterus, y Dr. C D. Lochrane; chorio-angioma of the lacenta, by Dr. Gilbert Strachan; a new method of erforming salpingostomy, by Mr. A. Gray; and a escription of a clamp forceps for controlling æmorrhage when performing myomectomy, by r. Bonney.—The Review of Current Litera- ure, under the directorship of Dr. Frank Taylor, rovides the reader with a very complete quarterly ncylopædia of current views throughout the world on bstetrical and gynæcological subjects, and it is ndeed a most valuable asset to all working at the pecialty.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the principal health statistics of Birmingham and Liverpool for 1922:—

City.	Estimated population (R.G.).	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Respiratory with influenza.	Infant mortality		Maternal mort. in childbirth.
							Legit.	Illegit.	
Birmingham ..	945,100	21·0	11·9	1·1	1·2	2·8	82	178	3·0
Liverpool ..	823,095	26·1	14·6	1·6	1·0	4·2	91	213	2·8

BIRMINGHAM.

Dr. John Robertson opens his report for 1922 with the following graphic statement:—

"Notwithstanding the continued distress arising from a large amount of unemployment and the horrible conditions in which many people are living owing to lack of proper housing facilities, the general health of the community was exceedingly good during the whole of the year. I believe that this maintenance of relatively good health has been due to the care taken by various organisations, but particularly the board of guardians and the Relief Committees, to enable the citizens who are in poverty to obtain sufficient food. I am of opinion that the lesson of the last two years, as well as one of the lessons we learned during the war, is that much more care ought to be taken by the community in providing an adequate supply of food of the proper quality, cooked in the proper way, and served at regular intervals. Not only was the general death-rate last year a good one for a large industrial town, but the infant mortality rate also was low, the incidence and mortality of most of the infectious diseases was relatively good, and, generally speaking, it is correct to say that Birmingham enjoyed unusually good health during this period of distress. All forms of tuberculosis were relatively low in incidence and in mortality."

Dr. Robertson thinks the Registrar-General's estimate of the population is over 17,000 too high. During the year the guardians gave relief to a proportion of the population varying from one-thirteenth to one-ninth, and unemployment insurance benefited a number of persons varying from 54,000 to 86,000. Care was taken to detect general deterioration of health, but no evidence of underfeeding or of obvious damage to the health of the people was obtained. During the past six or seven years measles has been less fatal than formerly, probably owing to the spread of knowledge by health visitors and district nurses as to the simple precautions necessary. Dr. Robertson thinks that further careful observation is necessary before the Schick test can be introduced into the ordinary practice of health departments. It is being tried at the City Fever Hospital. The Tuberculosis Department endeavours to mitigate overcrowding in families, invaded by tuberculosis, by loaning beds and bedding and 110 sleeping shelters, and also by supporting the applications of such families for municipal houses.

The following figures, showing the proportion of patients, whose sputum contained tubercle bacilli, treated during the six years 1913–18 and who are now working regularly, are interesting:—

Year.	No. treated.	Now working regularly.	Year.	No. treated.	Now working regularly.
		Per cent.			Per cent.
1913	505	22·1	1916	207	27·5
1914	573	28·2	1917	212	37·7
1915	308	24·6	1918	191	25·6

Some of the difficulties in the attempt to eradicate tuberculosis from the dairy herds supplying Birmingham with milk are indicated. At the beginning of the year 16 herds continued in the scheme, five in the city and 11 outside. One herd of about 21 cows which had been in the scheme for several years has dropped out. During the year there were six applications to be included in the scheme. Three of these six herds contained so many reactors that the owners decided not to continue with the scheme. The remaining three herds are to continue in the scheme, making a total of 19 herds in the scheme at the end of 1922. The approximate number of cows in these 19 herds is 501, of which 190 are in the five city herds. Of the 16 herds in the scheme at the beginning of 1922, only six yielded no reactors at the half-yearly testings; nine herds together yielded 20 reactors and the remaining herd yielded no less than 19. In the case of the last-mentioned herd of about 48 cows it is explained that the owner had not fully complied with the conditions, by promptly getting rid of 11 reactors found at the last testing. Most of the cows (in these 16 herds) which failed to pass the test were newly acquired cows which were purchased subject to their passing the test and were returned to the vendors. In some cases the reaction was doubtful, and when this occurs the cow is isolated and re-tested after a month or six weeks. In the city cowsheds, which house 1750 cows, only one tuberculous udder was found during the year. If we subtract the 190 city cows included in the "tubercle-free" scheme, this gives the surprisingly low figure of one tuberculous udder for 1560 stalls, which is a contrast to the Sheffield experience during 1922 of 23 tuberculous udders from 2350 stalls, or one tuberculous udder per 100 stalls.

Dr. Robertson gives tables showing that the infant mortality rate during the quinquennium 1918–22 was in the Central wards 108·6, in the wards of the middle ring 81·8, and in the outer ring wards 62·1; but that for the first few weeks of life there is very little difference between the mortality rates in the three groups of wards.

The total births in Birmingham last year were 19,850. Midwives attended 13,128 confinements, or about 60 per cent., and sent for medical assistance in 1987 cases, or over 15 per cent. of their cases. A systematic effort is being made to secure the coöperation of the midwives in carrying out ante-natal work, and an annual certificate will be issued by the health committee to each midwife who carries out these duties satisfactorily. Ante-natal registers are supplied to them free of charge and a urine-testing apparatus at cost price. In the case of any prejudicial ante-natal condition the midwife is to undertake to send or accompany the patient to her doctor, or to the maternity centre, if she has no doctor or is too poor to have one. Indiarubber gloves are supplied to the midwives and sterilised midwifery outfits to patients, both at cost price. There were 74 cases of pemphigus neonatorum with 11 deaths which came to the knowledge of the inspector of midwives. A special explanatory leaflet was issued to each midwife. The known damage to sight by ophthalmia neonatorum was—one case, left eye blind, right eye severely damaged, and another case, with a scar below the pupil.

The report of Dr. E. H. R. Harries, medical superintendent of Little Bromwich Hospital, contains some interesting particulars as to the working of a system of bed isolation or barrier nursing. The first 800 cases were treated with a wall-space of only 9 feet per patient. The system broke down six times in 800 cases, thrice after the introduction of chicken-pox in the incubation stage, twice after the introduction of measles at a very early stage, and once after septic scarlet fever. In a further series of 293 cases with 12 feet wall-space, there were two cases of cross-infection, after the introduction of incubating measles and scarlet fever respectively. Dr. Harries is of opinion that the eight failures in 1000 cases were due to a flaw in technique and to human-borne rather than air-borne infection. Incubating mumps was several times introduced without causing cross-infection, also whooping-cough.

The paramount need in Birmingham, as everybody knows, is more houses. During the year 902 houses were completed by the corporation and 382, mostly villas, by private enterprise. This number does not provide for the ordinary growth of the population. Dr. Robertson gives his reasons for thinking it is doubtful if ever private enterprise will again play any substantial part in providing small dwelling-houses. Conditions are getting more distressing, and Dr. Robertson regards it as incumbent on the municipality to keep on building.

LIVERPOOL.

Dr. E. W. Hope tells us that during the year further coöperation has been arranged among the Merseyside boroughs. In the event of any disease scheduled under International Agreements arising in any of these areas, the fact will be at once reported to the port medical officer for communication to the consular bodies. In the event of the outbreak assuming grave proportions the medical officer of health concerned will be entitled to call upon his colleagues for assistance. The possibility of unifying the small-pox system and so preventing the very undesirable multiplication of small-pox hospitals has also been under consideration, and steps have been taken in this direction. The provision of the new abattoir does not advance as quickly as Dr. Hope would like. The photographs which he gives of an up-to-date abattoir (Edinburgh) and of the wretched accommodation provided at the obsolete Liverpool abattoir are eloquent testimony of the urgency of this question. The city council have purchased a site of 7½ acres adjoining the Stanley Cattle Market (itself occupying 7½ acres) which is approached by railway sidings and adequate for all the purposes of a modern abattoir. Negotiations have been opened with the Mersey Docks and Harbour Board for the provision of a landing-place on the Liverpool side for imported cattle, but Dr. Hope does not think the scheme ought to be hung up pending the outcome of such negotiations.

The gravity of the position in regard to housing still remains, in spite of the fact that the corporation have erected upwards of 5000 houses and converted army huts into 488 bungalows during the last three years. The number of houses erected by private enterprise is negligible, and there are at the moment several thousands of applications from persons housed under bad conditions who are well able to pay reasonable rents for accommodation could it be found. "It is not necessary," says Dr. Hope, "to dwell on the position of families whose accommodation is limited to one room for all purposes, but it is clear that such conditions are gravely prejudicial to the public health and the welfare of the city." Some of the incidental results are an increased demand for admission to hospital for minor ailments and for maternity homes, increased risks of the spread of tuberculosis and of the quick relapse of patients returning from a sanatorium, and interference with education by the ill-health of children living under these conditions. A large part of the time of the health visitors is occupied in dealing with conditions arising from the house shortage. The Housing Committee are keenly alive to the unfortunate plight of thousands of applicants whom it will be impossible to house for a number of years at the present rate of building. It is, therefore, says Dr. Hope, a matter of urgent necessity that every possible facility should be accorded private builders in order to induce them to resume their normal industry.

Liverpool and the Merseyside boroughs have asked the Ministry to receive a deputation on the subject of compulsory treatment for venereal diseases. The matter was postponed pending the report of the Trevethin Committee, and Dr. Hope points out that this Committee in its report has recognised the necessity for special measures in special areas. Towards the end of the year legal, medical, and financial officers from the Ministry visited Liverpool to study methods in operation, and Dr. Hope expects that one point, in which efficiency and economy go hand-in-hand, is likely to be achieved—namely, the amalgamation of the medical inspection of school-children and the medical supervision associated with elfare work. During the influenza epidemic in the rly months of the year there was a great excess of male deaths, the excess being at the child-bearing ges and the age-period over 50. Altogether there ere 123 male and 210 female deaths recorded as om influenza.

A chart is given which shows that the marked decline deaths from excessive drinking which occurred oincidently with the restricted sale of alcoholic quors during the war still continues. A similar bservation applies to deaths of infants from suffocaon. Thirty deaths from gas-poisoning were recorded uring the year, 17 accidental and 13 suicidal. The odies of 438 stillborn babies were examined by the ity bacteriologist. Of these only 30 gave positive vidence of syphilis, while 21 were suspicious.

St. Paul's Eye Hospital of ten beds and cots for ne reception of infants (with their mothers) suffering om ophthalmia neonatorum has proved of great alue. Nevertheless, the damage to the eyesight of urvivors from this disease was considerable. In wo cases the sight of both eyes was lost, in two cases he sight of both eyes was seriously damaged, in three ases the sight of one eye was lost and the other eye as normal. Delay in bringing the disease under roper treatment is mentioned as a cause of these ad results. Ten cases died under treatment and the esult is not given in the case of five under private eatment, one in a Poor-law institution, and one emoval. The section of the Liverpool Corporation ct, 1921, dealing with the registration of lying-in omes came into force in April, 1922. The number of pplications received was 60 and of these 54 were pproved after investigation of the practice and remises. The number of rooms registered in the 4 homes containing 145 beds was 110, with 15 dditional emergency rooms. The number of live irths which took place in these homes was 482 and f stillbirths 10.

In the section dealing with tuberculosis interesting articulars are given of the after-history of Liverpool ases of non-pulmonary tuberculosis discharged from easowe Sanatorium. Of 260 cases discharged with he disease quiescent during 1919, 1920, and 1921, he following was the condition in December, 1922: 28 were fit, 13 had been readmitted for recurrence, 3 had been readmitted for deformities, 5 had ied, and 11 were not traced. Of the five deaths, wo were from phthisis, one from recurrence of the on-pulmonary lesion, and one from a non-tuberculous ause. In all except one the non-pulmonary lesion ad remained quiescent. A third of the 228 fit for ork "were unable for physical reasons to commend hemselves to an employer," and it is pointed out hat this raises the question of after-care or schools for his type of case, so that they can be taught some killed trade or specialised occupation which will ndow them with a greater labour value.

SCHOOL MEDICAL SERVICE.

Scarborough.

The axe of so-called economy has not spared carborough; it is unfortunate that it should have allen on the excellent nursery school which was the esult of the past few years' effort in this direction, nd was a feature of the school medical officers' revious reports. The nursery class established in he east end of the town is still alive in the Friarage School. The conditions here are not ideal, there is o garden, but it provides accommodation for between 0 and 80 boys and girls under 5 years of age. There ere 44 new admissions during the year. Fortunately, lthough unrecognised by the education committee, he Leamer-road Nursery School, which is a separate uilding with a large delightful garden, has not ntirely ceased to function—voluntary contributions re helping to keep it alive, and though the numbers n attendance have fallen, it is to be hoped that its clipse is only temporary, for its entire disappearance ould be a matter for regret not only to Scarborough ut to all educationists who have watched the growth of the nursery school movement. During the past year 1890 children were inspected in the routine age romps, and altogether 2809 children were medically examined. Dr. S. F. Linton complains that the worst cases of uncleanliness, of which there were 90 altogether, are not Scarborough children but children from industrial towns, and some cases have had to be cleansed at the clinic and their hair cut. The number of children found with ringworm was 66 as against 102 last year. The number is still high, and as there is no X ray treatment available, the school attendance of these children is seriously interfered with in spite of the most careful treatment with ointment. Dr. Linton experiences difficulty in persuading parents to have children with defective vision examined under a mydriatic. "The modern mother classifies it in the same category as vaccination —an unnecessary and unwarrantable interference with the comfort of her child." Of dental cases requiring treatment, 82 per cent. were dealt with. No means for general anæsthesia is available, although one or two cases especially requiring anæsthesia have been sent to the local hospital for treatment.

Dover.

Nearly one-half of the 5714 children in attendance were medically inspected in the routine group, and of these 902 had defects requiring treatment, while 294 were kept under observation. The school clinic was open for treatment on 188 occasions, the children treated numbering 1118, of whom 717 required dental treatment. There were 91 cases of ringworm, 131 less than the previous year, and the amount of impetigo also showed a considerable decrease. Cases treated have certainly covered a wide range: goitre 2, abdominal tuberculosis 2, tuberculosis of lungs 8, respiratory defects 15, vertigo 2, anæmia 13, pleurodynia 3, to mention only a few. There were also 56 cases of debility and 33 of enlarged glands. Dr. A. B. McMaster regards these two classes as very important, and urges that something should be done for the education and treatment of tuberculous and pre-tuberculous children such as these 56 cases of debility represent, stating that the number of such cases is increasing owing to economic conditions.

Northampton.

Since the beginning of the present year the school work has been under the supervision of Dr. J. D. McCrindle, who is also medical officer of health. Dr. G. H. Skinner, who resigned in October, 1922, has been responsible for the work dealt with in this report. Of 3162 children medically examined, 33 per cent. were referred for treatment or further observation, and of the 662 referred for immediate treatment 81·9 per cent. actually received it. The total number of cases of skin disease treated at the school clinic was 1027 cases out of 1140 cases reported.

The school dentist saw 2479 children, of whom 1436 received dental treatment. Mr. A. S. Anderson, the school dentist, states that during the six and a half years he has been school dentist here he has treated 9503 individual children, 5243 of whom had their teeth rendered absolutely free of decay. During that period he did not find any evidence to support the old theory that sugar is the cause of dental caries, and states that the poorest of poor children have the best teeth. "If they have it seems an odd argument, as the staple diet of such has been for many years bread with inferior jam, treacle, or syrup. Most of the children I find with perfect teeth admit the free use of sweets, while many with the worst are those whose parents say they have denied them sugar in any form." He suggests that children should be treated in the pre-school period. Many children, a number of them breast-fed, show well-defined caries on the eruption of the temporary teeth, and in some infants there is a rapid general dental decay, suggesting that the condition of the health of the expectant or nursing mother needs investigation. Decay of the permanent teeth is comparatively rare when any sign of decay in the temporary teeth has been thoroughly eradicated before the eruption of the permanent set, and Mr.

Anderson suggests that where treatment of a bad case has been delayed until the first permanent molars and incisors are in place the surfaces of contact and fissures are almost always chalky in appearance, and despite cleanliness are inclined to break down. This statement is one that should be taken seriously, and is one more indication that the pre-school age is the age to which more attention should be drawn.

MENTAL HOSPITAL REPORTS.

The annual report of the *Cardiff City Mental Hospital* is distinguished, as usual, by records of a large amount of research. Only brief outlines of the nature of these investigations are given, since much of it is to be published in extended form elsewhere. It seems unfortunate that the results of so large a volume of work should be scattered amongst various journals under different dates, or published only in abbreviated form in the report. The standing of the hospital is such that these reports might well be concentrated in a separate publication. The main bulk of the work under review was serological and chemical, the latter comprising estimations of various constituents in the cerebro-spinal fluid, blood, and urine, which have been carried on for some years, and the former a variety of attempts to identify toxins by animal immunisation with body fluids or extracts. A study has been made of gastro-intestinal function by radiography, and the effect of various intestinal antiseptics has been observed on the clinical condition of recent cases. Blood-groups, urea excretion in dementia præcox, and the basal metabolic rate have also been studied. Strangely enough, the only investigation the results of which are given in detail appears the least complete and discriminating of any, the bacteriological examination of urine from a series of 100 cases, a variety of organisms being found, some of which appear not to have been identified. As regards the general work of the hospital, a new departure has been made in forming a social after-care association, which, with the out-patient clinic and the hospital itself, should develop into "a complete organisation for dealing with the problem of mental disorders from the point of view of prevention, cure, and warding-off of relapse."

Several innovations and improvements are recorded in the annual report of the *Dorset Mental Hospital*. A house is being built for the assistant medical officer, and extensive reconstruction of the drainage system has apparently had the effect of abolishing enteric fever, which has been endemic for some years. A dental surgeon has been appointed, and an out-patient clinic established in Dorchester at the County General Hospital. The commissioner's report acknowledges with gratitude the readiness with which the management have considered and carried into effect such suggestions as he has made in the past. A considerable amount of pathological work has been done, and in order to allow the medical officers further time for this, the appointment of a dispenser is recommended. In view of certain treatment which has been undertaken, it appears to the commissioner desirable that this (and in fact any) institution should be provided with continuous and electric baths.

Reports and Analytical Records.

OLEO-BI.

(Hoffmann-La Roche Chemical Works, Ltd., 7–8, Idol-lane, London, E.C. 3.)

The introduction of bismuth as a specific remedy for syphilis was followed by an extensive trial of numerous preparations. Some 18 months ago at the Académie des Sciences MM. R. Sazerac and P. Levaditi brought forward evidence that tartrobismuthate of sodium and potassium in certain combinations, applied in the form of an ointment, prevented the development of syphilis if the application was made within one to four hours after contamination, while they expressed the opinion that bismuth lactate administered by the mouth retarded the breaking out of specific lesions. Last March in the *Schweizerische medizinische Wochenschrift* Dr. E. Ramel, of the Dermatological Clinic in Zurich, recommended an oleinate of bismuth, l'oleo-bismuth "Roche," the formula of which is $(C_{17}H_{33}COO)_3$—Bi. The preparation is now on the English market. In it the bismuth is very finely suspended and the stability of the suspension is so great that even after standing for months the solution shows no deposit. The treatment consists of bi-weekly intramuscular injections of 2 c.cm., 20 or 30 injections being given in one series, during which the total amount of bismuth administered is 2–3 g. The therapeutic results achieved in Zurich appeared to be equal to those obtained after the use of the French preparation Trépol. The results achieved during the past two years by the use of bismuth in the treatment of syphilis have stimulated the Hoffmann-La Roche chemical works to produce a second new preparation Tartro-Bi for which certain therapeutic advantages are claimed when employed intravenously.

PROTAGULIN.

(John Bell and Croyden, Ltd. (Incorporating Arnold and Sons), 50–52, Wigmore-street, London, W. 1.)

We have received a sample of this preparation, which is devised to bring about natural clotting of blood by the action of thrombin. It is supplied in the form of a powder, and so long as it is kept in properly sealed tubes will retain its potency for an indefinite period. It is issued in tubes of two sizes, the smaller size sufficing to make 1 c.cm. of solution with normal saline, the larger size containing enough to make double the quantity. The coagulant is prepared and standardised in the physiological laboratory of St. Mary's Hospital and is particularly recommended for use in hæmorrhage following extraction of teeth, in which capacity it has been noticed by Sir Frank Colyer in the last edition of "Dental Surgery and Pathology." The solution can be used upon gauze plugs in cases of epistaxis, or as an application upon gauze under a suitable bandage in cases of surface bleeding.

URAZINE.

(Dick, Coates and Co., 41, Gt. Tower-st., London, E.C. 3.)

Urazine, or citro-salicylate of piperazin, placed upon the market by Messrs. Dick, Coates and Co., is manufactured by the Laboratoire des Produits "Usines du Rhône," 21, Rue Jean Goujon, Paris. It is supplied in effervescent granules, the dose being one to two teaspoonfuls of the granules in half a tumbler of water, to be administered under the direction of the physician. It is usually found most convenient to take the drug with the two principal meals of the day. The chemical constitution of Urazine is as follows: 2 molecules of piperazin, 1 molecule of citric acid, and 1 molecule of salicylic acid united in 1 molecule of a "double" salt, which contains 343 parts of piperazin to 275 parts of salicylic acid, and 382 parts of citric acid. The intention is to combine the properties of salicylic and citric acids with those of piperazin whose action as a solvent of uric acid has been proved in the laboratory. As is well known, this solvent action of piperazin is a matter of discussion, but the experience of many gouty persons seems to be that their conditions are benefited by its exhibition. The preparation taken in the suggested dose makes an agreeable beverage, so that the drug may well be employed in many of the arthritic and neuralgic affections accompanying gout or rheumatic conditions.

Iodine-Medol.—In a note on this preparation, which appeared in The Lancet of Sept. 15th, we presumed that by the term "oxygenated hydrocarbon" was meant the mixture of liquid paraffin and oleic acid referred to in the British Pharmaceutical Codex under the name of "parogenum." Messrs. William Pearson, Ltd., desire to point out that the hydrocarbons in iodine-medol consist of oxygenated paraffinoids, whereas in "parogenum" there is no question of oxygenation.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 17, 1923.

THE PANEL SETTLEMENT.

THE panel crisis has become a panel settlement. As was anticipated, the Special Panel Conference on Wednesday last decided to accept as a whole the offer made by the Minister of Health in his letter of Oct. 31st, and to accept in particular alternative (*b*) in clause (5) dealing with remuneration. Accordingly, a special court of inquiry will be set up by the Minister as soon as possible and instructed to report on the capitation fee to be paid as from Jan. 1st next. The contract will be made on the basis of the fee recommended by the court of inquiry, the Government undertaking to go to Parliament for the necessary legislative sanction and the profession undertaking to accept the recommendation. The court of inquiry will be asked to report as soon as possible, hearing any evidence tendered on behalf of the Ministry, the profession, the approved societies, or other interested parties. No doubt the Insurance Acts Committee hardly felt itself justified in recommending any settlement which might involve financial sacrifice to many panel practitioners for years ahead. But panel committees themselves had accepted this sacrifice as the lesser of two evils, the Committee might have been glad to fall in with the other settlement which would have ensured a period of welcome peace. The Committee was willing to face the prospect of going through the same ordeal again in 12 months' time, and the Conference has agreed with their leading.

Widely divergent reasons may be given by interested parties for the decision reached by the Panel Conference. On a previous occasion of financial stringency the Conference accepted a reduction in the capitation fee from 11*s.* to 9*s.* 6*d.*, following an appeal of a Minister of the Crown to panel doctors to make some sacrifice for the common good in order to carry on an essential service for which at the moment their service could not be adequately remunerated—put briefly, the acceptance was on grounds of citizenship. The approved societies would certainly have argued that acceptance by the doctors of 8*s.* 6*d.* for five years, being in effect not more than a 6 per cent. rise on the fee of 1914, was a tacit admission that the service was overpaid at the earlier date. We think it may be taken that the Conference actually construed the position somewhat as follows. The Minister of Health, faced with a practically unanimous resignation from the panel, and having looked into the whole matter in a mood sobered by a serious position, decided that "under the present circumstances" so much, and so much only, could be paid out of insurance funds. Should this decision be modified or reversed by a court of inquiry, within a year the Minister—we speak of the office, not of the individual—convinced against his will would have the opportunity of showing that he held the same opinion still. But arguments were put forward to prove that the services and remuneration of the practitioners were not properly adjusted, these arguments remained unrefuted, and therefore the medical men were ready to face a court of inquiry. Two documents widely circulated during the past few days no doubt helped towards this decision. The first is a copy of the letter sent to the Minister of Health, on behalf of the executive bodies of approved societies, dated Nov. 1st, and signed by Sir THOMAS NEILL. This letter is a statement of the societies' case against "the proposal to appropriate towards the remuneration of panel doctors for the present type of medical service sums contributed by the insured population and their employers for other benefits." One may well ask what is here referred to? The Minister of Health is the trustee of all the funds contributed by insured persons, their employers and the State, towards an insurance scheme including many forms of benefit; it is incorrect to say that particular contributions are earmarked for any particular benefit, and equally incorrect to suggest that the taxpayer's contribution ought to constitute a separate fund. We now know from the Minister's formula which are the primary benefits under the Insurance Acts, and that the proper amount of remuneration to be paid to the doctors is a matter to be determined on its merits by the Government after due inquiry and after negotiation with them. Those who still are impressed by anxiety for other benefits under the Acts should refer again to a document read with great effect by Dr. H. B. BRACKENBURY at a previous Panel Conference,[1] in which this paragraph occurs:—

> "We agree that the service would be such as to justify a capitation fee to the doctors of substantially the present amount [that is, 9*s.* 6*d.*] without ruling out of the present consideration any claim by the medical profession for something beyond this, and we have satisfied ourselves that the National Health Insurance Fund in the aggregate contains sufficient money to meet the cost without lowering or endangering the provision of the other benefits, whether normal or additional, to which insured persons are entitled."

This document was signed by two members of the emergency committee appointed by the executive bodies of approved societies. In contrast to the official pessimism of the approved societies in regard to insurance finance, we have the report on National Health Insurance Medical Benefit prepared by the Joint Advisory Committee on Public Health and accepted by the Trades Union Congress General Council and the National Executive of the Labour Party. This document, of which we give a careful summary on another page, sets out in detail the various funds connected with National Health Insurance, including those in respect of which approved societies are officially regarded as having little, if any, financial interest. The conclusion at which the Joint Advisory Committee arrives is that it is possible, within the ambit of unallotted funds constituted out of present weekly contributions, to find sufficient to secure not only a continuance of the existing services, but also the introduction of various improvements, and this at a cost which would not deprive the insured persons of any of the benefits which they at present possess. Despite the alleged prospect of depreciation at the completion of the second valuation, there are certain profits to set off against losses—e.g., low sickness incidence, and a continuance of the improved interest-earning power of money. These two reports really balance each other out; and, whatever may be urged to the contrary within the next few weeks, the new Parliament can feel satisfied on the highest actuarial authority that the financial status of the present scheme will allow of continued development and the provision of adequately paid medical service.

---

[1] THE LANCET, Oct. 27th, pp. 948, 949.

No difficulty, we believe, will be found in obtaining Parliamentary endorsement of Sir W. Joynson-Hicks's offer. The Panel Conference has decided to refuse a prolonged period in which controversy might cease and during which a Royal Commission could decide what is in the best interest of the national health. A settlement for a period of five years would have had its points, giving ample time for the service to settle down again, while the Commission was affording opportunity for full investigation both of the immediate and potential value of the insurance service to the community. However, the Conference has decided on the bolder course, and courage commands esteem. We trust that no further attempt will be put forward to make health insurance entirely self-supporting. Properly developed and coördinated, the scheme of medical services under the Insurance Acts should become, as years go by, the most important of the agents of the Ministry of Health for improving the health and safeguarding the lives of the industrial workers.

◆

A STUDY OF OSTEITIS FIBROSA.

Though our knowledge of morbid histology still leaves much to be desired and authorities differ among themselves on the interpretation of facts which are accepted by all, our conceptions of the morbid processes of the body rest, on the whole, upon a fairly sound structural basis. The skeletal system is, however, a glaring exception to this generalisation. While in most pathological laboratories histological examinations are made every day of the digestive, respiratory, circulatory, or genito-urinary organs, bones are but rarely microscoped, and because of this we know very much less about diseases of bone than we do about diseases of other tissues. The explanation lies, of course, in the technical difficulties which must be overcome, and the amount of time and labour involved in the preparation of satisfactory histological material from the skeleton. To examine a diseased bone with anything like the same thoroughness which is commonly devoted to a sclerotic kidney or an interesting tumour would occupy so long that in the routine of a busy laboratory the task is seldom attempted, and this aspect of morbid histology is poorly represented in the current literature.

In view of these considerations, pathologists will welcome the appearance of the October number of the *Edinburgh Medical Journal*, for it is devoted entirely to a long paper by Dr. James W. Dawson and Mr. John W. Struthers on Generalised Osteitis Fibrosa with Parathyroid Tumour and Metastatic Calcification. These authors describe the remarkable case of a man, 49 years of age, who first came under observation in January, 1921, on account of delayed union of a fracture of the humerus. X ray and microscopic examination of the humerus showed a condition of fibrosis and decalcification suggesting an early stage of osteitis deformans, and similar changes could be detected in the cranial bones. After a very brief period in hospital the patient's condition, both local and general, showed extraordinary improvement, and X rays demonstrated the redeposition of lime salts in the humerus. He left hospital, but returned within a few weeks with a second fracture of the bone which healed in about five weeks. After a period of good health he was seized with a sudden heart attack, and was again admitted to hospital, but died a few hours afterwards. Post-mortem examination revealed an extensive condition of osteitis fibrosa of the left humerus, femur, and of the bones of the skull. The left lower parathyroid body was converted into a papillary adenoma, and practically all the organs showed calcareous infiltration. The authors describe in detail, illuminating their text by many admirable illustrations, the histological changes in the affected bones. The general conclusions arrived at are that the fixation of calcium and the metabolic activities of bone are controlled by the bone cells, which, in turn, are themselves under the influence of hormones derived from the parathyroid glands. The parathyroid adenoma in this case is regarded as an indication of an abnormal physiological state, an anatomical hyperplasia reflecting a functional hyperactivity called for by the needs of the bone cells which had been injured and rendered physiologically impotent by some unknown agent.

These views may or may not receive general acceptance, but this complete record of a case forms a most valuable addition to the literature of the subject. The paper contains, however, more than the record of a single case: it is a clear and critical presentation of current knowledge and teaching of the pathological processes involved in bone dystrophies. Such debatable processes as halisteresis and metastatic calcification are discussed very fairly and with full references to the literature, and the various neoplastic giant-cell formations are analysed in detail. In short, the authors are to be congratulated upon a piece of work which will be of actual assistance to most workers in this field, and of interest to all

◆

PSYCHOPATHIC SYMPTOMS IN MINERS' NYSTAGMUS.

While the mechanism which produces nystagmus in miners may be in doubt two things are certain. Nystagmus may be present without causing subjective symptoms, while psychopathic symptoms, such as tremor, disordered action of the heart, and sleeplessness, occur in miners with or without oscillations of the eyeball. To these facts we called attention in discussing not long ago a new theory of coal-miners' nystagmus. In a letter which appears on p. 1110, Mr. W. Inman returns to this important issue. The second report of the Miners' Nystagmus Committee of the Medical Research Council makes clear that it is not the nystagmus alone that demands compensation. Compensation is paid largely for the associated psycho-neurotic symptoms, and the Committee suggest the adoption of a stricter standard of physical signs. But what physical signs exist beyond the nystagmus? The standardising value of photophobia and blinking of the eyelids is discounted by the observation that they occur commonly in shell shock, for in that association they are unhesitatingly regarded as hysterical. Mr. Inman suggests that the oscillation of the eyeballs may itself be only a part of a psycho-neurotic state. He really offers two possibilities: that the nystagmus is a harmless physical eccentricity, upon which it chances that psycho-neurotic symptoms are hung, as upon a peg; or that it is only one symptom, and not a constant one, of a psycho-neurosis which, though it occurs in miners, differs in no other way from disorders with which we are already familiar. An obvious objection to the latter possibility is that nystagmus occurs generally as part of certain organic disorders and can only very exceptionally be imitated. But non-volitional manifestations, such as tachycardia or tremulous eyelids, are common in the psychoneuroses, and, though they are valuable diagnostic indications, yet they may be absent in patients with disabling mental symptoms, or, on the other hand may be almost the only indications of a psycho-neurotic state. Nystagmus behaves similarly. It may be present in a severe degree in certain cases without interfering with the man's working capacity, whilst the third schedule to the Workmen's Compensation Act seems to reduce diagnosis to an absurdity by speaking of "the disease known as miners' nystagmus, whether the symptom of oscillation of the eyeballs be present or not." The report notes, too, that the nystagmus may disappear as the associated symptoms increase. This sequence is a commonplace in clinical psycho-pathology and was the rule in shell shock; the initial manifestations—coarse tremors, mutism, paralyses, and the like—usually disappeared and subjective troubles increased.

Current opinions as to ætiology are supported by statistics which show a correlation between the incidence of the disorder and the use of the safety-lamp, though Dr. FREDERICK ROBSON[1] produced figures showing a correlation with the presence of a high percentage of gas in the mine. Both these correlations are capable of a unifying interpretation, for the miner is inevitably aware of the significance of the safety-lamp or the presence of gas. The word *safety* in this connexion hints at *danger*—it is the naked candle that indicates safety—and fear of the dangers of the miner's calling may well tend, as fear always does, to produce a psycho-neurosis. The miner's traditional courage in face of real danger provides no contradiction to this hypothesis, for it is not the expression of fear, but its suppression, that leads to the outbreak of symptoms. More difficult to reconcile with the hypothesis is the observation that the incidence of nystagmus declines when illumination is improved, the danger obviously remaining unchanged. Every psycho-neurosis has many determinants. Compensation is potent in increasing this disability, and this fact alone should arouse suspicion of affinities with what may be termed the compensation neuroses. But this suspicion must not lead to the assumption that stoppage of compensation will arrest the psycho-neurosis. There may be a pitfall in deductions drawn from the absence of nystagmus in other countries, for though "suggestion" cannot produce a psycho-neurosis it may determine a symptom, and we might find that nystagmus is replaced, in those countries where compensation is not given, by other manifestations the nature of which is unsuspected. That a psycho-neurosis is prevalent in particular circumstances is an indication that those circumstances are such that the ordinary man finds it difficult to adjust himself to them; and the mental and physical stress of a miner's life cannot be denied. Indeed, in this subject the psycho-pathologist would meet new problems at every turn, and Mr. INMAN's hypothesis is disquieting by the difficulties which it suggests.

As long as the inquiry was confined to a search for a physical cause there was hope of a definite and simple solution. Indeed, on the assumption, which is held by many distinguished authorities, that the main cause of true miners' nystagmus is defective lighting, considerable efforts have been made to remove at least one important factor in its causation. The complexity of the problem of miners' nystagmus is indefinitely increased if it must be investigated anew from the psychological aspect. Yet, if that aspect possesses the significance that Mr. INMAN suggests, there is every reason for the fullest inquiry, both on economic grounds and on account of the clinical importance of the principles involved.

---

Annotations.

"Ne quid nimis."

STANDARDISED DRIED MILK.

THE Minister of Health has circulated to local authorities the regulations[1] in regard to the labelling and composition of dried milk which will come into operation on May 1st, 1924. These are in general similar to the regulations affecting the sale of condensed milk issued earlier in the year.[2] From the prescribed date no one will be allowed to offer for sale any dried milk intended for human consumption unless it conforms to a definite standard and is distinctly labelled to that effect. Milk described as dried full-cream milk must contain not less than 26 per cent. of milk fat, if described as three-quarter, half, or quarter-cream milk, not less than 20, 14, or 8 per cent. respectively of milk fat. Skimmed milk—that is to say, dried milk containing less than 8 per cent. of milk fat—must bear a label upon which is printed in bold letters the fact that the milk is unsuitable for feeding infants. The actual label in this case is as follows:—

DRIED MACHINE-SKIMMED MILK
[or DRIED SKIMMED MILK].
UNFIT FOR BABIES.
THIS TIN CONTAINS THE EQUIVALENT OF
(*a*) PINTS OF SKIMMED MILK.

Severe penalties are laid down for wilful neglect or refusal to carry out the regulations, and all those who are interested in child welfare will welcome these provisions as they did the provisions in regard to condensed milk. The purchaser of dried milk will obtain full information as to the value of the article bought, and it will be his own fault if he is misled or misinformed. We can only hope that the central health authority will continue its beneficent campaign against misleading descriptions of essential foodstuffs. The regulations will help the honest traders.

SEDIMENTATION OF ERYTHROCYTES IN NERVOUS DISEASE.

IT has long been known that the rate at which erythrocytes settle in a column of blood varies greatly, but it is largely owing to the recent investigations of the Swedes, Fahræus and Westergren, that this phenomenon has been exploited and made the principle of a delicately graduated test. It was found by Fahræus that in the healthy male the rate of sedimentation of the erythrocytes in a tube with a diameter of 1 cm. is about 3 mm. per hour, and in the healthy non-pregnant female it is about 5 mm. We recently called attention to the work of Dr. Mironesco, of Bucharest, on the sedimentation test as applied in certain acute infectious diseases.[3] In a paper published in *Paris Médical* for Sept. 29th by two other Bucharest physicians, Dr. Paulian E. M. Démètre and Dr. N. Tomovici, it is shown that this test is remarkably instructive in certain diseases of the central nervous system. The technique followed by the authors was perfectly simple. Into a 1 c.cm. syringe there was first aspirated 0·2 c.cm. of a 5 per cent. solution of sodium citrate, a vein was then punctured, and enough blood aspirated to fill the syringe. The citrated blood was then transferred to a tube with a diameter of 4 to 5 mm., and the extent to which the column of erythrocytes had sunk was recorded in millimetres every 15 minutes. It was found that in tabes the rate of sedimentation is greatly increased, particularly during the first quarter of an hour. As one of the published charts shows, the rate of sedimentation in a case of tabes was 12 mm. in the first quarter of an hour, 6 mm. in the second, and 2 mm. during the following half hour. The chart referred to indicates graphically the normal rate of sedimentation, the curve of which appears almost horizontal when compared with the abrupt fall of the curves of three cases of tabes. In the healthy male there was a fall of only 1 mm. during the first quarter of an hour, and the same rate of sedimentation was maintained throughout the test. In marked contrast to this straight and almost horizontal line was the tabes curve, which showed an abrupt fall, followed by a gradual flattening. In general paralysis the authors found a fall of 12 mm. in the first quarter of an hour and 4 mm. in the second. Still more interesting were their findings in cases of paraplegia due to various causes. When the paraplegia was not due to a specific disease the rate of sedimentation was slow and practically normal, but when the paraplegia was due to syphilis or to Pott's disease this rate was greatly increased. The curious observation was made that the rate of sedimentation is not the same in true Parkinson's disease (paralysis agitans) and in post-encephalitic Parkinsonism. In the former it is comparatively rapid, being 18 mm. in the first half hour. In the Parkinsonism following lethargic encephalitis the rate of sedimentation is only about 1 mm. every quarter of an hour. These findings suggest that the close clinical similarity of these two conditions is only superficial, and that their underlying causes are distinct.

THE "MILITARY SURGEON" AND ITS EDITOR.

THE October issue of the *Military Surgeon* announces the sudden death of its very able Editor, Colonel James Robb Church, after six years in office. Colonel Church was 57 years of age, having qualified in 1893 at the George Washington University Medical School and retiring from the United States Medical Service in 1917 with the rank of Colonel, to become Secretary-Treasurer of the Army Medical Museum at Washington. The journal which he edited is the official organ of the Association of Military Surgeons of the United States, and has recently completed its fiftieth volume. The *Military Surgeon* is packed with interesting information, and has for many years provided us with a critical review of army medical equipment as seen from a standpoint differing from our own. In the October number Surgeon E. R. Marshall, U.S. Public Health Service, tells what the United States are doing for their lepers, who are estimated at 1000 persons. Congress in 1917 provided sufficient funds to establish a national "leprosarium," and in 1921 the Louisiana State Leper Home at Carville, with 358 acres, was bought for the nation. At present it has 172 beds; plans have been prepared for 500, and, when these are achieved, Congress may make provision for 1000. Patients are received at their own request, but they can be apprehended, under the law, and detained. There is an unclimbable fence (with 12 strands of barbed wire) around the estate, and there are a farm and tennis-courts; mention is made of a player-piano, gramophone, and two moving-picture shows weekly (to which the patients have by subscription added a third); thus amused, they are almost contented in their isolation. Patients are treated with the ethyl esters of chaulmoogra oil and in some cases their condition is improved, the improvement reaching a maximum in six months. Great care is taken of the eyes of the lepers. A dentist found that 70 per cent. had pyorrhœa, and 17 per cent., after serological examination had been made, proved to be also affected with syphilis. Major M. A. Reasoner, Medical Corps, U.S. Army, who has done duty with the U.S. troops in Coblentz, reports on an observation trip in Germany, Denmark, and England, made in spring this year. He comments on the open sale of contraceptives in London, and states that "the present economic conditions are so bad, and there is so much unemployment and such a lack of housing facilities, that it serves to some extent as an excuse. Unfortunately for the good of the country, it gets the people into bad habits, and if this keeps up, they bid fair to rival the French." He adds, one regrets to see, "In no place in Europe have I seen so many bleary-eyed, besotted wrecks of humanity as in London." He is pleased with the work of the hospitals in Germany, especially the pathological work, but finds them financially in a bad way. Yet he thinks Germany is doing better work in chest and abdominal surgery than across the Atlantic, although in every other way the United States surgeons are ahead. With Denmark he is very pleased: "Standards in medicine and surgery are unusually high"; "the best equipped laboratory I have ever seen" is that of the National Serum Institute at Copenhagen, and the hospitals "do not seem to suffer the want of anything." Lieut.-Colonel A. P. Francine, Medical Officers' Reserve Corps, U.S. Army, argues that mustard gas was a disabling, not a destructive weapon, and in fact much more humane than shot and shell; it left little subsequent permanent damage.

ANGINA AGRANULOCYTOTICA.

UNDER this title Dr. Friedemann,[1] director of the Infectious Diseases Department of the Rudolf Virchow Hospital, Berlin, who records four fatal cases in women aged from 22 to 57, describes a form of gangrenous angina accompanied by high fever and characterised by a complete or almost complete absence of the neutrophil leucocytes in the blood, while the other elements of the bone marrow, especially the blood-platelets, are present in normal numbers. All the cases hitherto observed have proved fatal in two or three weeks' time. Soon after the onset of the disease sore-throat develops, and a severe angina occurs which at first closely resembles diphtheria, but with progressive destruction of the tonsils assumes the appearance of necrotic angina. The characteristic feature of the disease, however, is the blood picture. The leucocytes are present in extremely small numbers, in some cases less than 1000 per c.mm. The results of a differential count are more striking still, as the leucocytes are found to consist almost entirely of lymphocytes, and the neutrophil polymorphonuclears are entirely absent, or only a very few can be found after a prolonged search, while the other elements of the bone marrow are present in normal quantity. This isolated absence of the neutrophil polymorphonuclear leucocytes has not hitherto been described in any other disease. The autopsy findings are not characteristic. The absence of any myeloid changes in the spleen, liver, and bone marrow is remarkable. Nothing definite can be said as to the ætiology of the disease. Nothing characteristic is seen in smears from the tonsils, spirochætes or spirilla being absent in all cases. The blood cultures were negative in three cases, and in another three cases fairly abundant colonies of *B. pyocyaneus* were found, but this organism was probably not the cause, but only a secondary invader. The pathogeny also requires elucidation, as it remains to be seen whether the change in the blood picture is the result of the angina or whether the angina develops with a pre-existing agranulocytosis. The diagnosis is difficult at first, owing to the resemblance to severe diphtheria, but the commencing necrosis of the tonsils should suggest angina agranulocytotica. A diagnosis is not possible from the clinical appearances alone, as these are very similar in streptococcal angina necrotica, severe specific angina, and the angina in leukæmia and other blood conditions. The blood picture alone is decisive. The prognosis, according to the cases reported by W. Schulz and Friedemann, is very bad, but it is an old experience that in a newly discovered disease it is only the severest cases that are seen at first, while the milder forms escape recognition. Further observations will show whether the disease has really such an unfavourable course as it appears to have at present. It is impossible to say now whether angina agranulocytotica is actually so rare as might be supposed from the few cases published, for it is possible that many of the cases described as malignant diphtheria with negative cultures were really examples of this disease.

"SCHOOLS IN THE SUN."

FOR a long time past schools in the sun have been available in the summer for many groups of continental children. During last summer the opportunity arose in connexion with Stowey House open-air school for delicate children under the London County Council. Only one class was started and the experiment was tried under a sympathetic headmaster and with frequent visits from the school doctor. The summer did not prove very favourable for such an experiment; May and June were overcast, July was better, but in August, when insolation was good, the school was closed. In spite of this drawback and the fact that the school was in London the results have been very encouraging, and the headmaster has been pleased with the outcome both from the mental and the physical side. The boys themselves showed great keenness, and no difficulty was found in obtaining the coöperation of the parents. Other classes, indeed, were anxious to be allowed to join in, and a further trial will be made next year. We learn also that sun treatment has been carefully carried out during last summer under the supervision of Sir Henry Gauvain at King George's Sanatorium, Bramshott, where there are a number of sailors of various nationalities suffering from surgical tuberculosis. Here also the results were satisfactory, and the men were keen to avail themselves of the treatment right on into the autumn. While undergoing sun treatment the patients are encouraged to undertake manual work, basket-making, and the like. The monotony of long-enforced recumbency is thereby alleviated, the patients are happier and more contented; discipline is improved. The combination of heliotherapy, aerotherapy, and occupation has proved of great value in the treatment of these adults, and the contrast between the appearance of these patients and similar cases for whom such advantages are unobtainable is striking.

EXPERIMENTS ON PLAIN MUSCLE IN VITRO.

USING various types of plain muscle—e.g., uterus and intestine of the cat, guinea-pig, and rabbit, the sphincter of the iris of the cat, and the retractor penis of the dog—and suspending them at 38° C. in an appropriate saline, whose hydrogen-ion content could be varied, Prof. C. Lovatt Evans and S. W. F. Underhill[1] have been able to study the movements of the excised surviving organs under varying conditions of hydrogen-ion concentration. Since oxygen or other gas bubbles through the surrounding fluid, attention must be paid to the fact that plain muscle is extremely sensitive to mechanical stimuli. It was found that the effect of increase of hydrogen-ion concentration, within limits compatible with life, is to cause relaxation of the tone of plain muscle. Rhythmical contractions, such as those of the small intestine, are slowed and depressed in extent on the acid side of neutrality, and quickened and depressed when the reaction becomes decidedly alkaline. Excessive acidification leads to death in a relaxed state. In muscle preparations devoid of tonus increase of hydrogen ions has no effect. These effects are independent of action on local nervous mechanisms. When the preparation is immersed in a definitely alkaline bath of phosphate solution (pH 8 or more), addition of acid oftens produces an increase of tonus or a large contraction. This effect, well seen with the guinea-pig uterus, is believed to be due to alteration in the ionic calcium content of the fluid, and not directly to the hydrogen-ion concentration. The experiments also show that the mechanism of contraction and tonus in plain muscle is different from that in striated muscle. In the same issue of the journal Prof. Lovatt Evans records also some interesting observations on oxygen consumption in the tissues. The surviving uterus and the small intestine of various animals—the mucosa was in some cases left intact, in others removed—were used in two different methods, and both gave similar results. When in tonus the muscle uses less oxygen than when relaxed; this is because the surface of the fibres is reduced. After a period of oxygen lack, the oxygen consumption is increased. A higher temperature, within physiological limits, increases the oxygen usage; the maximum is reached at 43° C. The temperature coefficients at different ranges of temperature are not the same, but as in other instances show a diminution with rise of temperature. In view of the fact that cyanides check the oxygen usage of tissues generally, small additions of sodium cyanide were tried. Cyanides depress, but apparently do not abolish, the oxygen usage of the tissue.

DIURNAL INCONTINENCE IN WOMEN.

THAT incontinence of urine is one of the most distressing afflictions which occur in women who have borne children is generally conceded. Minor degrees of this uncomfortable symptom are very common in women over 40 years of age, especially when some effort is made which produces sudden abdominal strain, such as coughing or sneezing. Attention has recently been directed to this subject in various papers, more expecially in communications by Prof. B. P. Watson, of Edinburgh, at the British Congress of Obstetrics and Gynæcology, and by Mr. Victor Bonney at the Royal Society of Medicine. The most recent contribution is that of Mr. F. H. Seymour before the Brighton and Sussex Medico-Chirurgical Society, in which he expresses surprise that British gynæcology has paid so little attention to this condition. That may be true of published work, but we feel sure that most gynæcologists are aware of the inconvenience caused to women by this symptom, and even if advice is not directly sought on this point the question is commonly put in the out-patient department and the consulting-room. Mr. Bonney has, however, very rightly drawn attention to the importance in the diagnosis between urethrocele and cystocele. Treatment directed towards relief of the latter will not cure incontinence commonly associated with the former. A point emphasised both by Mr. Bonney and Mr. Seymour is that the causation of incontinence in parous women in many cases is in no way connected with genital prolapse, but is due rather to a very typical displacement of the urethra. In these patients the urethra, on expulsive efforts such as coughing, wheels round the subpubic angle with the result that for a brief moment it looks forwards and upwards. It is at this moment that the incontinence occurs. The causative factor appears to be relaxation of the "pubo-cervical muscle sheet" which normally supports the female bladder, and more particularly the anterior third of this sheet. An interesting observation is that incontinence of this type is more likely to occur when the bladder contains very little urine than when the organ is full. The dilatability of the vesical sphincter in women is, of course, well known, for comparatively large calculi have been removed per urethram without any subsequent incontinence. Should the symptom, however, occur as a result of laceration and trauma of the sphincter through the extraction of large calculi, the dribbling of the urine is continuous and, we think, in the opinion of most surgeons difficult to rectify. The spasmodic incontinence noted by Mr Bonney and Mr. Seymour is, on the other hand, relieved in the majority of cases by a plastic operation designed to reinforce the unstriped muscle fibres beneath the urethra by means of buried unabsorbable sutures. In the technique described by Mr. Bonney the urethra is exposed by a vertical incision through the anterior vaginal wall and the sutures are introduced transversely. Should a cystocele be present, this simple operation is combined with an anterior colpoplasty. No pessary apparently suffices to cure incontinence of this type.

OXYGEN STORAGE AND TRANSPORT.

THE use of oxygen in medicine, although comparatively infrequent, is of high importance, chiefly for the reason that when it is needed it serves a purpose which cannot be met by any substitute. To make our meaning clear, we need only refer to its employment in conjunction with anæsthetics and to its use in extreme conditions of pulmonary insufficiency. The work done by the Oxygen Research Committee and the report[1] which they have recently issued are, therefore, of especial interest to medical men. The fundamental problem before the Committee was to try to furnish, especially for aeronautical, medical, and other scientific purposes, more ready means than those existing for the utilisation of oxygen. In the view of the Committee, and our readers will share it, there is urgent need, for use in hospitals and for other special purposes, of cylinders even lighter than those which were recommended by the Gas Cylinders Committee. It will be remembered that in 1921 this Committee recommended and specified lighter cylinders for trade use. The Research Committee has been principally concerned with the possibility of increasing the use of oxygen in its liquid form. The difficulties of economic production on a commercial scale are great and are not dealt with in this report. A great part of the report deals with double-walled metal vacuum vessels, the chief vehicle for transport of liquefied oxygen or air. A number of experiments and of highly complicated physical investigations bear witness to the labours of the Committee. These do not, however, much concern the medical practitioner; he will be more interested in the question of the price of oxygen, which, as the Committee state, at present "restricts its use for medical purposes to quantities much below those in which it could usefully be employed." Unfortunately the Committee declare themselves unable to express any opinion as to the possibility of reduction in the present cost of oxygen.

PERI-ARTERIAL SYMPATHECTOMY.

THIS operation has been hailed as one of the most important advances in modern surgery; it formed an extremely interesting demonstration at the Zurich Surgical Clinic during a recent visit from British surgeons. Recent accounts, however, suggest that the hopes entertained are not being fulfilled. Leriche, with whose name this operation has been associated, has pointed out that the notoriously refractory behaviour of certain ulcers and other lesions is due to vasomotor-trophic disturbances, and that a scar or other morbid condition in the periphery may start a reflex travelling to the central nervous system through the peri-arterial network of sympathetic nerves to be found in the outer coat of the large arteries to the limbs. By the simple expedient of removing a circular strip of the outer coat of these arteries he anticipated that a break could be made in this injurious reflex, the vaso-constrictor action being abolished, and more favourable conditions for nutrition being restored to the parts concerned by the local vaso-dilatation and hyperæmia supposed to follow this operation. Most physiologists believe that the vaso-constrictors belong to the sympathetic system, but run only to a certain extent in the peri-arterial network, some following the course of the spinal nerves. The vaso-dilators, on the other hand, run only with these spinal nerves. Other physiologists, however, believe that all the vaso-constrictor nerves, as well as all the vaso-dilator nerves, run with the spinal nerves, that the nerve supply of the large blood-vessels is strictly segmental, and that the sympathetic nerves do not run continuously with the large arteries to the periphery. It is obvious that so long as these fundamental matters are in doubt, the rationale of peri-arterial sympathectomy must be "in the air." As for the clinical results obtained from this operation, it would seem from a recent communication[1] by Dr. Klug to the *Naturhistorisch-medizinischer Verein*, in Heidelberg, that they are very modest. His own experience of 16 cases operated on at Enderlen's hospital has not been favourable, although great care was exercised in the selection of cases and the technique of the operation was sedulously correct. In every case temporary hyperæmia of the parts distal to the field of operation did, indeed, occur after the operation, but the former state of affairs soon recurred. Observation of the peripheral blood-vessels with the capillary microscope also suggested that the beneficial effects of this operation were only transitory, and tests with adrenalin and other substances failed to show any essential differences between the limb operated on and its fellow. It is evident that the Leriche operation is at present under a cloud, and it would have been better if its physiological foundations had been securely established before it was passed on to the clinician. But as a stimulus to physiological research in this field the operation may, after all, have served a useful purpose.

INFLUENCE OF DIET ON INTESTINAL FLORA.

THE cry of "intestinal infection" having become almost a slogan of a certain school of clinicians and bacteriologists, Prof. L. S. Dudgeon was wise to point out in his presidential address to the Section of Tropical Diseases and Parasitology of the Royal Society of Medicine that this term is sometimes employed without clear understanding as to its significance. The presence of abnormal bacteriological findings in the fæces is not evidence of intestinal infection, because in the healthy subject the most efficient means for the discharge of bacteria is by the fæces. Harvey Cushing and Louis Livingood[2] many years ago classified the intestinal flora into (1) permanent or obligatory intestinal bacteria, (2) transient or facultative forms. They considered that the members of the first group are invariably present, while in the case of the second group the bacteria appear only after they are introduced with food or by similar means. These transient bacteria do not find in the presence of the permanent flora cultural conditions which favour their perpetuation, unless they encounter or produce a pathological lesion of the mucosa. The obligatory forms, in their opinion, are also dependent to some degree upon dietetic influences. During recent years, the bacteriological methods employed for the study of the intestinal flora have been considerably modified and elaborated. Results based on such methods of investigation, however, are open to countless fallacies unless the influence of the following factors is fully appreciated: (1) The patient's diet, and the length of time such diet has been in force; (2) the condition of the mouth and throat as to the presence of pyorrhœa, or other inflammatory lesions; (3) the presence of a pathological process in the intestinal or respiratory tract; (4) whether there is diarrhœa, constipation, or normal action; (5) the influence of purgatives; (6) the time interval between the collection of the specimen from the patient and the bacteriological examination; (7) whether contamination of the specimen of fæces with urine, or from unclean vessels, or exposure to atmospheric conditions, especially in the tropics, has occurred.

---

[1] Department of Scientific and Industrial Research. H.M. Stationery Office. 8*s*. 6*d*.

[1] Deutsche med. Wochenschrift, Sept. 28th, 1923.

[2] Johns Hopkins Hospital Report, vol. ix.

It is largely due to the lack of knowledge of the bacterial flora of the intestinal tract in man, under normal and abnormal conditions, and of the numerous circumstances which influence the flora, more especially dietetics, that common errors are so often repeated and inaccurate deductions made. To quote but one example, it is not an uncommon occurrence for a patient, whose diet consists of cow's milk, to be treated with a streptococcal vaccine made from the fæces. G. B. Morris, R. L. Porter, and K. F. Meyer [2] lay stress on the fact that the fæcal flora of a child fed on cow's milk, although not suffering from any intestinal disturbance, or symptoms of intoxication, may resemble the putrefactive stool, due to direct milk contamination. As a result of elaborate investigations, these authors considered it to be an established fact that the microbic flora of the intestinal canal is in direct relationship to the diet of the host, and that the absence of carbohydrates in a diet produces a predominance of proteolytic bacteria, resulting in putrefactive stools and symptoms of intoxication from intestinal absorption. In adults the importance of chronic intestinal putrefaction has led to various methods of treatment being employed, such as vaccine therapy, intestinal antiseptics, removal of the colon, and the one-time popular remedy of implanting antagonistic organisms, such as *B. bulgaricus*. P. R. Cannon [3] points out, however, that observations have shown how impossible it is to implant *B. bulgaricus* in the intestinal tract, since the organism is apparently not an inhabitant of the normal intestine and cannot adapt itself to its new environment. Cannon's observations agree with those of other observers who claim that the reduction of intestinal putrefaction can be effected by the substitution of carbohydrates in the diet for proteins. The controlling force of the intestinal bacteria in the normal intestine is the food which is consumed. Prof. Dudgeon fully endorsed a statement by Torrey [4] that milk and a high casein diet stimulate a vigorous growth of saprophytic streptococci and enterococci. It would be well for this fact to be more fully appreciated by those who make use of streptococcal vaccines prepared from the fæces.

THE LIMITATIONS OF AVAILABLE INFORMATION ON CLIMATOLOGY.

A DETAILED account of British climatology is being prepared by the Meteorological Office of the Air Ministry. Section IV. of this work, which has appeared,[5] consists of two parts: (A) Range of Variation of Temperature and Rainfall; and (B) Frequency Tables for Hail, Thunder, Snow, Snow-lying, and Ground Frost. The information covers varying periods terminating with the year 1921 and concerns 30 selected places ranging from the Shetland Islands to Scilly, from Dublin to Yarmouth. The range of information given in (A) with regard to any special places is wide. We are told, for example, the highest temperature reached on a normal day in, say, January; in which January, over a term of years, were there (*a*) the hottest, (*b*) the coldest days on the average; what was the lowest temperature reached in the normal January night; in which January were the nights (*a*) warmest, (*b*) coldest; what January was (*a*) the warmest, (*b*) the coldest on the whole, and what was (*a*) the highest, (*b*) the lowest temperature recorded in January since 1876. Similar information is given with regard to the rainfall. In (B) we find details concerning the highest number of days for each calendar month, with snow, hail, and thunder; also the frequency of winters (1881–1915) with no snow, with 1–10 days snow, with 11–20 days snow, and so on. On this mass of detail in the contents, which may well prove of interest to holiday-makers, agriculturists, and invalids, some comments may be made from the medical standpoint. It must nowadays be admitted that thermometric readings alone are quite inadequate as a guide to the effects of atmospheric conditions upon the human body. A doctor would be unable to advise a patient correctly as to a suitable residence as regards sensations of heat and cold unless he knew as much about the prevailing winds as about the temperature of resorts. Temperature is only one of the important factors concerned, movement of air being equally, if not more, important. The ordinary thermometer being unaffected by wind, is quite unable to indicate the changes of sensation produced by movement of air, and though indoor conditions may be indicated fairly by its readings a kata-thermometer which is affected by both temperature and wind is needed for the estimation of outdoor conditions. While the kata-thermometer directly estimates the cooling power this may also be calculated indirectly from the velocity of the wind and the dry bulb temperature. From information already collected it is probable that cooling powers could be worked out. At any rate kata-thermometer cooling powers should also be estimated in the future, and in this way information of real value to doctors and invalids may be forthcoming; a suitable self-recording kata-thermometer (Schuster's) is now obtainable. It is well known that, in industry, the wet-bulb temperature is a better guide to comfort than the dry-bulb. Again, at low temperatures moisture of the air increases the sensation of chilliness. A doctor must then know at least the wet-bulb temperature, and the cooling power before his advice may be of much value to a patient. The ideal volume for the doctor would contain the hours of sunshine, the dry-bulb temperature, the wet-bulb temperature, the cooling power and the velocity of the wind.

EPIDEMIC DIAPHRAGMATIC PARALYSIS.

Dr. G. C. Payne, epidemiologist of the Virginia Board of Health, and Dr. C. Armstrong,[1] of the United States Public Health Service, describe an epidemic of transient diaphragmatic spasm, which occurred mainly in the north-eastern part of Virginia during the summer of 1923. In practically all the areas affected the epidemic began in July, but there were a few cases in May and June. The infection appeared to be spread through families by contact. Among 17 families studied by the writers there were five cases in one, four cases in one, and three cases in two others. Children were somewhat more frequently attacked than adults. Of 27 cases under the writers' observation 15 were less than 20 years of age, and 8 were not yet 10. The epidemic was strictly confined to rural communities. Prodromal symptoms were usually absent, and the attack nearly always began suddenly with severe epigastric pain, which later extended to one or both sides of the lower part of the thorax. Respiration was very difficult, the rate in some cases being 60 a minute. The temperature rose in nearly all cases at the onset, and soon reached the maximum, which ranged from 101° to 105° F. The pain was intermittent, was most severe at the onset or soon after, and was increased by active movements of the body. Profuse perspiration was the rule. Nausea and vomiting occurred in about one-third of the cases. Constipation was the rule. More than half the patients complained of headache, and a few of pain in the extremities or in the lumbar vertebræ. After about ten hours of severe paroxysms and dyspnœa the patient became more comfortable and the temperature fell, but sometimes it rose again, and some patients complained of weakness and slight fever for from one to three weeks after the onset. In some cases there was no return of the pain and dyspnœa, while in others the initial symptoms recurred with decreased severity after an interval of 24 hours or more. Blood counts, which were made in 11 cases, showed no definite increase in the total number of leucocytes. The polymorphonuclears ranged from 25 to 76 per cent. In six cases the eosinophil percentage was greater than 5, the maximum being 13. The sequelæ noted were streptococcus empyema, dysentery, otitis, and endocarditis. The writers regard the outbreak as due to an infection the nature of which has not been determined. A similar epidemic which occurred in Virginia in June, 1888, was described by Dabney, who emphasised its resemblance to dengue, but regarded it as a distinct entity.

ITCHING AND TICKLING.

Prof. M. v. Frey, of Würzburg, has published[1] some new and interesting observations on the physiology of tickling and itching and the relation between the sensations of tickling and those of contact and pressure. These experiments show that the sensation of superficial tickling, that form which is discharged from the skin, is determined by the nerves of the pressure sense, while that of itching is due to the superficially placed nerves which administer to painful sensations. An appropriate method whereby the sensation of tickling may be induced by cutaneous stimuli is to draw a pig's bristle, 5 cm. in length, along the skin of the forearm at the rate of 1 cm. per second and exercising a pressure of about half a gramme in so doing. To excite the sensation of itching press a pointed bristle on the skin and maintain the pressure on one and the same spot, using a pressure of about half a gramme. The two sensations are quite distinct, as shown by the fact that the effective stimuli so far as they are of a mechanical nature have a different liminal intensity or threshold value. The mechanical stimulus exciting the sensation of itching cannot be diminished much under half a gramme, if it is to be effective, while sensation of tickling can be induced when the pressure is reduced even to one-twentieth of a gramme. The tickling sensation, such as is produced by the bending of a hair or deformation in the region of a pressure spot, rapidly fades or subsides, a phenomenon characteristic of the terminations of pressure nerves. To maintain the sensation of tickling, the stimulus must be carried along the skin. For itching, however, the stimulus must be maintained at one and the same spot and the sensation once induced remains for a long time at the affected spot. Moreover, the reaction time for tickling is very constant and is about 0·15 second, while the corresponding time for itching varies with the spot stimulated and is relatively long, being seldom less than one second, and may be even seven times longer than that for tickling. Different also are the after duration and the reflexes associated with the two sensations. The itching sensation in general outlasts the duration of the stimulus, which can hardly be said of tickling excited by weak stimuli. The reflex associated with itching is the scratch reflex, that with tickling is shuddering or even shivering, and not laughter as is so generally assumed. The correspondence between the threshold stimulus for tickling and contact, the difference in the threshold between surfaces provided with hairs or hairless parts, and the marked increase of the threshold value after removal of the hairs—the increase may be tenfold—also serve to strengthen the contrast. If the pain nerves present in the epidermis be paralysed by cataphoresis, it can be shown that tickling is not due to excitation of these nerves, for the sensation can be evoked after they are paralysed. In spite of the distinctive characters of the two sensations, confusion and admixture are not infrequent, and long-continued titillation may give rise to results which are very complex and may be associated with the sensation of itching. There is a close relation between the sensation of tickling and that of contact, and both are readily elicited by touching the hairs; both are very fugitive when the stimulus remains applied. Both sensations tend to extend beyond the spot stimulated, and both lead to reflex vascular effects. The physiological effects in both processes are not essentially different, and the psychological effect is chiefly dependent on the direction of the attention to the phenomena. If this is directed to the external stimulus, the sensation of contact arises, but if to the part tickled, the sensation of tickling arises. The author comes to the conclusion that the sensations of contact, pressure, and tickling are modifications of one modality and are not due to qualitatively different receptors.

DUODENAL FEEDING.

Prof. Max Einhorn,[1] of New York, reports satisfactory results on 11 cases of gastric and duodenal ulcers treated with duodenal feeding, by means of a duodenal tube. He only includes those cases in which a definite and persistent deformity of the stomach in the shape of a notch at the site of the lesion was demonstrated by the X rays. The patient was fed through a duodenal tube for two to three weeks, at the end of which time the notch was found to have either completely disappeared or to have considerably diminished in size, while the patients expressed themselves as feeling well. In Prof. Einhorn's opinion, these cases should be given a chance of healing by his method before they are subjected to operation, although he admits that there are some cases in which there is good ground to justify immediate operation. We should like to have further reports of his cases, after a prolonged period of observation, to ascertain whether they tend to relapse, as it is well known that most gastric ulcers show signs of periodic activity, with free intervals between the attacks. We also feel that there may be grave danger of missing an early carcinoma in subjecting all cases to medical treatment, when X rays show a definite deformity.

AN UNFORTUNATE ERROR.

A MISCONCEPTION has arisen under which, we are informed, medical women have been told that they were not expected at THE LANCET Centenary Dinner at the Hotel Victoria on Nov. 29th. This is an entire mistake. Any member of the medical profession can be present at the dinner, and already many medical women have signified their intention of being present.

THE veteran Pridgin Teale died at his residence, Headingley, Leeds, on Tuesday last, at the advanced age of 92.

WE regret to announce the death, in his eighty-fourth year, of Emeritus Professor D. W. Finlay, late of Aberdeen University, at Helensburgh, Dumbartonshire, on Nov. 4th.

SMALL-POX IN ENGLAND AND WALES.—During the week ended Nov. 3rd, 35 new cases of small-pox were reported in England and Wales from the following areas: Derbyshire 3 (Chesterfield 2, Shardlow R.D. 1); Durham 2 (Gateshead 1, Southwick-on-Wear 1); Gloucestershire 7 (Gloucester 6, "including 2 cases of chicken-pox re-diagnosed as small-pox," East Dean 1); Notts 16 (Hucknall 15, Basford R.D. 1); Yorks West Riding 7 (Adwick-le-Street).

MANCHESTER HOSPITAL FUND.—During the last year over £73,000 was subscribed by three-quarters of a million contributors, a capital sum sufficient to enable 13 Manchester and Salford hospitals to be left free of debt. The Duke and Duchess of York made a special visit to the city to receive and hand over to the Hospital Fund this large cheque. The Duke congratulated the Lord Mayor on the inception of a scheme so successful, which would go far to prevent curtailment of the work in the wide field covered by the hospitals of Manchester and Salford.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XLV.

THE TREATMENT OF CŒLIAC DISEASE.

THE modern treatment of cœliac disease, although not apparently curative, is very successful. It is able to change a perpetually ailing, fretful, and unattractive child into one who is free of all symptoms, happy and ovable. There are few more grateful women than the mothers of the severer cœliac cases which have been recognised and treated. Yet, although the disorder has been known for more than 30 years and is by no means uncommon, much unnecessary suffering is frequently caused by its passing undiagnosed.

Recognition of Cœliac Disease.

The essence of the disorder is a failure properly to absorb the fat of the food. Although apparently efficiently split by the pancreatic juice, a large excess of the dietetic fat remains unabsorbed. On this disability rest all the other symptoms. The cardinal features of the disease are: (1) excess of fat in the stools; (2) enlargement of the abdomen without signs of organic disease; (3) retardation of physical growth and development; (4) anorexia, often of the severest grade; (5) fever, either low and persistent or high and transient. Less common complications are tetany, convulsions, "alimentary" œdema, and, I think, megalocolon with visible peristalsis. "Late" rickets s rare.

Course of Disease.—It is not yet possible to say when the disorder begins and ends, for we find that even in the absence of symptoms fat-absorption remains below the normal. But the times of the onset and termination of symptoms are known. Occasionally the first symptoms, the passage of colourless stools, will appear quite suddenly towards the end of the first year of life, usually in association with teething; but more commonly pale diarrhœa (*diarrhœa alba*) is seen for the first time towards the end of the second year. From this time onward, n the absence of treatment, the symptoms already enumerated will be seen for many years. Towards the later years (10 or 12) of childhood, even in the absence of treatment, some improvement in fat-absorption seems to occur, but in the most quiescent stages analysis of the stools will show that a normal condition has not been reached. The lack of growth eads to considerable stunting and in severe cases to retarded sexual development (cœliac infantilism). Nevertheless growth continues for many years, and under treatment a normal average height is eventually reached. Whether in adult life fat-absorption ever becomes entirely normal I do not know, but certainly the patients are ultimately able to keep well on an ordinary diet. Except for attacks of severe diarrhœa n the early years, the disease is not dangerous to life; neither does it predispose towards tuberculosis.

Diarrhœic Type.—This is the common classical ype described by Gee in 1888. The characteristic feature is the *diarrhœa alba*, the stools being very large, unformed, pale, greasy, and extremely offensive. In frequency they vary from 2 or 3 up to 10 or 12 daily during bouts of diarrhœa. On analysis they show a great excess of fat, the dried stool containing 30–80 per cent. of fat. In these pale stools the bulk of the fat is passed as fatty acid crystals; bile-pigment is not absent from the stools, but it is masked by the excess of fatty acids. In this type of the disease the other symptoms are severe and the stunting of growth most noticeable. Mentally the children are in no way deficient, but are usually neurotic, hysterical, ntrospective, negative, and "difficult." It is noteworthy that even in this severe form it is seldom recognised at home that it is the fats of the diet which disagree. Mothers think in terms of pastry, cream, green apples, and so on, rather than in those of protein, fat, and carbohydrate. Occasionally, however, one is told that cod-liver oil, with which the children are often liberally dosed in quiescent intervals, "does not seem to suit."

Non-diarrhœic Type.[1]—This is the same condition in milder form. It is much less easily recognised than the former type. A case may conform to this type throughout its course, but it is chiefly seen in the quiescent or convalescent stages of the classical type. It differs from the diarrhœic type in two particulars: (1) The stool, although larger than normal, is neither pale nor unformed nor offensive; it is formed and coloured, and may be dark, hard, and constipated. Yet it contains a considerable excess of fat (30–50 per cent.), but the bulk of the fat, instead of being in the form of fatty acid which masks the bile-pigment, is present in the form of soap which takes up the colour. (2) The symptoms of abdominal enlargement, lack of growth, anorexia, &c., are milder than in the diarrhœic type or stages.

Management of the Case.

General Scheme.—The principle of the treatment is to work out a diet containing the optimum amount of fat—that is to say, one on which there will be satisfactory growth and a complete absence of symptoms. As this will certainly contain less fat than an ordinary diet, parents should be warned that the child is not being starved and that extra fat, if given, may lead to loss of appetite or worse upsets. As the child improves on the low-fat diet, the growth of its appetite will enable more food to be given; this should be supplied in the form of extra non-fatty proteins.

Fatty Foods.—The chief foods in a child's diet which are rich in fat are milk, butter, dripping, cream, meat-fat, gravies, milk and suet puddings. Many preparations prescribed for children contain much fat—for example, cod-liver oil preparations, virol, &c. Liquid paraffin appears in the stools as neutral (unchanged) fat.

Detailed Treatment.—Leaving until later cases first seen when in an attack of severe diarrhœa, the treatment of the ordinary chronic case may be undertaken in the following stages:—

1. Before starting treatment note the amount of fatty food in the diet, the characters of the stool, and symptoms. If possible have an analysis made of the stool for fat before altering the diet. These points serve to give a rough standard of a diet too fatty for the particular case. The child should be weighed every week or so, and particularly before any alteration in the diet. Its height should be measured every three months. The mother should keep notes of these points and of the diet ordered and its alterations.

2. Change the diet abruptly on to one low in fat. The following dietary may be used as a start. For very young children it will probably be rather too rich in fat; for older cases it may be unduly strict.

Breakfast.—Plasmon cornflour made with skimmed milk; fish, egg, lean tongue; toast or bread; no butter; syrup, jelly, jam; cup of skimmed milk flavoured with Schweitzer's cocoatina or tea, sugar. 11 A.M. (if desired) bovril made with water, rusk or dry biscuit.

Dinner.—Fish; lean meat, chicken, rabbit; bovril in water to replace gravy; potato and second vegetable without sauce. Pudding; jellies, stewed fruit, rice boiled in water, sponge-cake puddings; alternate or every third day, plasmon puddings or milk puddings made with skimmed milk, or steamed pudding containing a trace of butter. Fruit, except bananas and nuts. Drink: water.

Tea.—Bread, rusks or dry biscuit with syrup, jelly, or jam; no butter: sponge-fingers; a little lettuce or watercress: meringues (cases only); tea or cocoatina made with skimmed milk: home-made buns or cakes containing a minimum of butter.

Supper.—Sponge-fingers, sandwiches of raw meat pulp, of watercress, of tongue, or tomato; plasmon pudding made with skimmed milk. Drink: skimmed milk with or without plasmon, or cocoatina or bovril.

Note.—(1) Skimmed milk. Unless machine-skimmed milk can be bought the skimming should be done by heating the milk at 200° F. for 20 minutes and then setting aside for three hours. All the cream can then be carefully removed. Done properly the milk should have a blue look and contain under 1 per cent. of fat. A desiccated skimmed milk (Lyons's "Kookal") may be used for emergencies. (2) Plasmon is a powder made of casein in a soluble form. It is stated to contain only 0·7 per cent. of fat. Plasmon arrowroot, blanc-mange, cornflour, and custard powders are said to contain no added fat; the plasmon cocoa, chocolate, and biscuits contain added fat and are unsuitable. Plasmon oats contain a large percentage of plasmon, but porridge is seldom suitable for cœliac cases. (3) Schweitzer's cocoatina is advertised as being fat-free. Ordinary cocoas, of course, contain fat.

---

[1] THE LANCET, 1923, i., 72.

3. When the child has been on this diet for two or three weeks reconsider the position. If the diet is correct the stools should have become normal in size, the abdomen smaller (but not normal), the colon no longer distended with gas, the tongue clean, and, most important of all, the appetite keener. The rule at this stage, as at others in the treatment, is to reduce the fats sufficiently to get the child hungry and eating well. Finally, an analysis of the fæces will show that the percentage of fat in them has dropped, probably to between 20 and 30 per cent. This figure, which usually means that the child is safe from any recrudescence of active symptoms, is diagnostic of the disease; on such a low-fat diet the percentage should be far lower.

4. When the appetite has improved increase the non-fatty protein in the dietary. Now the child should begin to increase in weight and height, and such a diet may be kept on for months; indeed, it forms the basis of the diet for years.

5. When the child is thoroughly stable and doing well, experimental tests of giving more fat may be made. These must not be hurried and must be most carefully watched. A little extra fat may be tried every third day; the most welcome relaxation is "scrapes" of butter, or anchovy-paste or potted meat for breakfast. Other tests may be easily planned. It must be remembered that many of these children are extraordinarily sensitive to fat, one meal containing too much fat, as, for instance, a greasy gravy, is quite enough to upset them. Also, it by no means follows that what a child can take every third day can be tolerated daily. The signs of disagreement will be distension of the colon, coated tongue, loss of appetite, irritability, and perhaps a foul stool.

6. *Drugs.*—An alkaline mixture, such as rhubarb and soda, with or without bromide, is very useful, and may be continued regularly. Bile salts are often of value, particularly in the diarrhœic cases. They lead to an increased absorption of fat, and so allow more fat to be given in the diet.[2] They should be given for periods at a time; I usually order them for alternate months so that their influence can be tested. They are best administered in the form of the "kapsols" as made by Allen and Hanburys, each gelatin capsule containing ½ gr. each of sodium taurocholate and glycocholate. One capsule, or in older children two, should be given after each meal with the alkaline mixture. I have never seen any harm come of their use.

For the stunting of the growth I have not found any benefit from the use of thyroid or pituitary extracts. Correct dieting is the remedy for stopped growth. This suggests that the lack of growth is not merely the effect of fat-deprivation, but is largely the result of the toxæmia produced by an excess of unabsorbed fat.

Acute Diarrhœic Attacks.—In this condition it is probable that the excess of fatty acid in the bowel has set up an enteritis. These attacks are chiefly seen in the youngest patients and should not occur under treatment. For them all fat must be cut out of the diet temporarily. Water should be given, then clear whey or plasmon in water until skimmed milk can be allowed. Bismuth and opium mixtures and colonic irrigation may be ordered.

SOME POINTS ON NEPHRITIS IN GENERAL PRACTICE.

BY HUGH MACLEAN, M.D. ABERD., D.SC.,
M.R.C.P. LOND.,
PROFESSOR OF MEDICINE, UNIVERSITY OF LONDON,
ST. THOMAS'S HOSPITAL.

BY the use of modern facilities it may safely be said that the presence or absence of nephritis in any given subject can be ascertained with certainty; indeed, it is generally not a very difficult problem to determine with reasonable accuracy to what extent the renal tissue is damaged and what the probable prognosis is. All this necessitates the use of a laboratory and the carrying out of certain tests, some of which require technical knowledge and a great deal of time. On the other hand, the very simple procedure of estimating the urea of the urine after giving a dose of urea by the mouth—the so-called urea-concentration test—frequently affords all the information that is required. It is essential, however, that certain factors associated with this test should be clearly understood, otherwise the interpretation of the results obtained may be difficult and even misleading. In this respect the relation of blood-urea concentration to nephritis and other conditions is very important. Within the last few years much stress has been laid on the necessity for ascertaining the amount of urea in the blood in all cases of nephritis, but it is now clear that, in some patients, blood-urea alone may afford little or no clue to the condition of the kidneys.

Blood-urea and Nephritis.

The amount of urea found in the blood of the normal healthy individual on an average diet is generally given as 20 to 40 mg. per 100 c.cm. blood. In a general way, experience shows that the younger the individual the nearer does the value approach to 20 mg. per 100 c.cm., while in older subjects there is a tendency for the upper limit of 40 mg. per 100 c.cm. to be reached or exceeded. These figures are by no means very constant, especially in old people, and it is not uncommon to find a blood-urea of 60 mg. or even more per 100 c.cm. blood in an elderly person in whom the kidneys are apparently fairly normal for his age. Thus, the presence of a blood-urea of 60 mg. per 100 c.cm. in a young person of 18 or 20 would be very significant, while a similar concentration in a patient aged 70 might be of little or no importance. To be of value in clinical work the age of the patient must be taken into account when considering the value of a blood-urea concentration. The part played by diet in this connexion is so obvious as to need no further discussion. It should always be remembered that a renal lesion must be fairly extensive before it will result in a raised blood-urea, for it is common knowledge that the removal of one kidney, for instance, with the consequent reduction of renal tissue to one-half the normal, does not cause an increase in blood-urea. Probably, nearly three-quarters of the kidney substance must be thrown out of action before the defect is indicated by retention of nitrogenous products in the blood. From this it is obvious that examination of the blood affords little or no help in early stages of nephritis where the lesion is as yet a comparatively slight one. Indeed, it is possible to have a fairly severe attack of acute nephritis without any increase of blood-urea. When the blood-urea is very definitely raised as the result of a renal lesion, that lesion must be a severe one, and a high blood-urea in such cases really indicates that the greater part of the renal tissue is either temporarily or permanently out of action. In mild cases of nephritis, estimation of blood-urea is therefore of little value, for it may be within the normal range or even lower. In severe nephritis, no doubt, the amount of retention of nitrogenous products such as urea serves as a valuable guide as to the extent, and particularly as to the progress, of the lesion, but under certain conditions even a low blood-urea value does not necessarily exclude renal involvement. In patients bordering on uræmia, and with a high blood-urea content, it is frequently possible by a modification of diet to reduce the blood-urea to the normal limit. Such patients, however, do not appear to improve as the result of the lowering of nitrogenous waste products in the blood, and they frequently die in uræmia, despite all dietetic precautions. From this it would appear that urea in the blood plays little or no part as a causative factor in the production of uræmia. While all this is generally understood, it is frequently forgotten that a high blood-urea may be produced by causes acting outside the kidneys altogether. It is essential that this fact should be remembered when dealing with certain cases of nephritis, otherwise grave mistakes may be made as to the condition present and the probable prognosis.

---

[2] THE LANCET, 1920, ii., 894.

Importance of Blood-urea in Severe Acute Nephritis.

In one class of case—that of severe protracted acute or subacute nephritis—the real condition of the kidneys can be more satisfactorily ascertained by following the changes in blood-urea than by any other means. Frequently such patients are very ill for a few months after the original acute attack, and the general clinical condition may be so bad as to give little hope for recovery. Œdema and ascites are often prominent features, and dyspnœa, bronchial catarrh and gastro-intestinal symptoms may be much in evidence. After some time these patients frequently appear to take a turn for the better, this change being coincident with a definite lessening of the œdema. In such patients the clinical picture may give an entirely wrong impression as to the prognosis, for instead of improving the renal lesion may be progressing rapidly, and the outlook may be quite hopeless. In the majority of cases of protracted acute nephritis with severe œdema there is a tendency for the œdema to diminish as sclerotic changes progress in the kidney. Since many of the patient's symptoms, such as vomiting and dyspnœa, are apparently associated with the œdema, these symptoms may cease with the subsidence of the œdema, and the patient may appear to be recovering. Frequently, however, at this point the renal condition is becoming rapidly worse, and the superficial clinical evidence may be entirely misleading. Instead of the increased blood pressure becoming lower with the diminution of the œdema it still persists at a more or less high level, and this in itself is suspicious though not necessarily of grave significance.

In this type of case estimations of blood-urea at intervals of a week or 10 days give invaluable information. Whatever the clinical condition of the patient, a steady increase of the blood-urea indicates a hopeless prognosis, and I have not yet seen a single case in which a fatal issue did not supervene when the blood-urea was steadily rising, or was maintained at a high level for a considerable time. To some extent these patients are in somewhat the same position as the subjects of subacute infective endocarditis. Frequently, in the latter condition, the symptoms improve during apyrexial periods to such an extent that superficially the patient appears to be on the way to recovery, yet a fatal termination always ensues, and generally within a few months. It is just the same with certain cases of acute nephritis that do not clear up. Though the clinical condition frequently suggests improvement, the result is never in question. Some of these, of course, may have acute disease grafted on to a chronic lesion, but in others this is almost certainly not the case.

On the other hand, however severe the symptoms in such cases, it is found that when the blood-urea comes down steadily the outlook is good, and the patient gradually recovers. In these severe, more or less acute, cases frequent estimations of blood-urea will give more information than can be obtained by any clinical means, and often prevent gross mistakes in prognosis.

High Blood-urea with Healthy Kidneys.

Various factors will produce a considerable increase in blood-urea, even when the kidneys are quite normal. Abstention from fluid for a comparatively short time, especially in hot weather, may result in raising the blood-urea very considerably, so that a value of 60 mg. or more per 100 c.cm. blood may be found in a young healthy individual. Persistent diarrhœa will give similar results. The question of food also plays a very considerable part. Besides these factors, there are various extrarenal pathological conditions which give rise to a marked increase of blood-urea. Such conditions as cardiac disease, acute or subacute obstruction of the intestines, pneumonia, empyema, fevers, and other pathological processes are perhaps the most prominent agents in the production of this result. In such conditions the kidneys, though perhaps implicated to some slight extent as a secondary phenomenon of the disease, may be quite efficient in the performance of their function, and cannot in any way be held responsible for the accumulation of blood-urea. This fact is frequently forgotten, and in such cases the finding of a high blood-urea is often taken as proof of the presence of a definite renal lesion. Not infrequently slight nephritis may be associated with some other lesion which gives rise to retention of urea in the blood. This is seen, for instance, in subjects in whom both cardiac and renal lesions occur together. In these patients it is not uncommon to find a comparatively high blood-urea, while other renal tests indicate that the kidneys are but very slightly involved. Here the high blood-urea would seem to indicate that the kidney condition was very bad, but the other tests suggest the very opposite.

How are we to explain such anomalous results? The fact is that the high blood-urea is really dependent on the cardiac condition and not on the kidneys at all; from the blood-urea alone it would, of course, be impossible to say whether the chief defect lay in the renal or cardiac mechanism, but the divergence between the result of the blood-urea test and other renal tests is at once proof that the high blood-urea cannot be dependent on renal deficiency. Frequently, with cardiac improvement, the blood-urea becomes normal in such patients, and on subsequent examination all the tests indicate that the kidneys are satisfactory. On the whole, we are forced to the conclusion that a knowledge of the blood-urea content does not help us very much in forming an opinion as to the condition of the kidney unless we are certain from other symptoms or tests that the case is really one of nephritis. If we do not know this, we must always consider carefully whether high blood-urea is due to nephritis or to some extrarenal condition. Even when associated with albuminuria it is very unsafe to assume, without definite evidence, that a renal lesion is present, and the lack of appreciation of this simple fact occasionally results in tragedy. As an instance of this I may refer briefly to the case of a patient who was suffering from albuminuria and began to show vague symptoms which his medical adviser thought might be due to nephritis. A blood-urea estimation was carried out, when a concentration of 95 mg. per 100 c.cm. blood was found. The combination of albuminuria and high blood-urea satisfied his medical attendant that the case was one of chronic nephritis with uræmic symptoms. Some time afterwards examination of the urine of this patient revealed the fact that the amount of urea present was nearly 3 per cent. Despite all the apparent evidence that the patient was suffering from uræmia, it was now necessary to reconsider the diagnosis, for a urine containing this large amount of urea definitely and absolutely excluded the possibility of uræmia. Further examination showed the presence of an abdominal abscess which, as the subsequent history showed, was the cause of the high blood-urea.

In another case almost exactly the same thing happened. Here, again, uræmia was at first diagnosed but later definitely excluded by the finding of a high urea percentage in a specimen of urine. Further examination showed that the patient was suffering from an empyema which was responsible for the diagnosis of uræmia. Unfortunately, the correct diagnosis was made too late, and the original diagnosis of nephritis and uræmia cost this patient her life. Such mistakes have very frequently been made, simply because it is not remembered that the presence of albuminuria and high blood-urea do not necessarily indicate that the symptoms are dependent on kidney lesions. In all doubtful cases a sample of the urine should be taken and the urea estimated. If the kidneys are efficient the percentage of urea in the urine will be fairly high—say, somewhere in the region of 2·5 to 3·5 per cent., or even more. Indeed, if the concentration of urinary urea reaches 2 per cent. uræmia may be safely excluded.

In severe nephritis, on the other hand, the urine contains a comparatively low percentage of urea, generally in the neighbourhood of about 1 per cent. The accumulation of urea in the blood in nephritis depends on the fact that the kidney has to a large extent lost the power of concentrating urea in the urine, and so it follows that the urine passed by a uræmic patient must be deficient in concentration of urea. When the increase of blood-urea is dependent on some extrarenal cause, the healthy kidney has to deal with a large "head" of urea in the blood, and will consequently secrete a urine containing a high percentage of urea. If we have a patient presenting apparently uræmic symptoms with albuminuria and a high blood-urea, it may be quite impossible to say whether the condition is one of uræmia or not if we restrict ourselves to the ordinary clinical evidence. If we now examine a sample of urine for urea and find that the urea percentage is, say, 2·5 per cent. or more, we may take it for granted that the symptoms are not dependent on renal disease. In such a patient further investigation will generally reveal some other cause for the condition. If, however, the urine contains only 1 per cent. of urea or so it may be taken for granted that the kidneys are very inefficient and that uræmia is present. For differentiating uræmia from many conditions which simulate it the most reliable measure that we possess is the estimation of the urea in the urine. This simple process can be carried out in five minutes by the busiest practitioner; it requires no practice or skill in chemical manipulation, and has the advantage that it affords more definite evidence as to the condition of the kidneys than do any of the more elaborate tests. This statement is based on experience with very many thousands of cases, and while it must be admitted that no single test will suffice in all cases of renal involvement, yet there are many patients in whom this test will provide all the information that can be required.

If it is known that a high blood-urea is present examination of an ordinary sample of urine suffices; if the blood-urea concentration is unknown, it is necessary, in suspected cases, to give a large dose of urea by mouth, so as to make certain beforehand that the kidneys will have a large "head" of urea to work on. A full description of this urea-concentration test is given in my book[1] on renal disease, and only the shortest reference to it need be given here. The patient is given about 15 g. of urea dissolved in a couple of ounces of water, the bladder being emptied immediately after taking the urea. The total contents of the bladder are then voided at intervals of one hour and two hours after the urea is taken, and the percentage of urea in the specimens ascertained. One very important feature in the use of the test is the necessity for preventing the patient having too much fluid in the system, for under these circumstances the urea may act as a diuretic, and so much water may be excreted that the actual percentage of urea may not at all represent the maximum concentrating power of the kidney. As a rule, not more than 120 c.cm. of urine per hour should be passed after the urea is taken. Sometimes, patients come to be examined after copious draughts of tea or other beverages, and here the results of the test may be inconclusive and difficult to interpret. By far the best results are obtained by asking the patient to take as little fluid as possible for 12 to 18 hours before the test. This is a most important precaution which has perhaps not been sufficiently emphasised in the past, though I have been accustomed to carry it out for several years. When this is done, experience of a very large number of patients shows that the urea-concentration test is the most reliable method we have for the estimation of renal function. It also possesses the advantage that only very small amounts of urine are required for analysis—a most important consideration in many cases of genito-urinary surgery where samples have to be obtained from the ureters. Obviously, neither this test nor any other is capable of indicating whether a single kidney is diseased unless ureteric specimens are taken, for one kidney will secrete a urine of exactly the same concentration as the secretion derived from both kidneys. While it may be difficult to carry out the more elaborate tests for renal function in general practice, this urea-concentration test should be used by every practitioner because of its extreme simplicity and usefulness. This test, combined with an examination of the urine for protein, casts, blood, and other elements will, in the great majority of cases, suffice to determine the condition of the kidneys. Estimation of blood-urea will help to complete the picture, but this estimation is frequently unnecessary, and, when done, must be very carefully considered in the light of the points already mentioned.

Nephritis and Arterio-sclerosis.

The comparative frequency of a general breakdown in health in middle-aged business men of more or less free and active habits is quite noteworthy. Such patients are often found to suffer from marked cardio-vascular changes. The arteries may be somewhat hard, the blood pressure raised, and the heart considerably enlarged, while examination of the urine shows the presence of protein and often of some casts. The diagnosis frequently made in such a patient is chronic nephritis with secondary cardio-vascular involvement, but it is an interesting feature that many of these individuals possess quite satisfactory kidneys. Experience shows that, to a great extent, the outlook in patients suffering from these cardio-vascular changes depends largely on the condition of the kidneys, for when the kidneys are markedly involved and cardiac and vascular changes are present as well, then it may be said at once that the outlook is hopeless. Many of these patients die within a year. On the other hand, when the kidneys are found to be functioning well, the outlook is, as a rule, not nearly so hopeless, and indeed may be reasonably good. In cases of this nature a complete investigation of renal function should be carried out and the prognosis based largely on the results of this examination. Here, however, a word of warning is necessary, for it is often impossible to say from the result of one examination what the probable outlook is. Renal efficiency tests will indicate the condition of the kidney at the time the tests are done, but are quite incapable of affording any clue as to the progressiveness of the disease. If possible, therefore, it is best to defer giving an opinion as to prognosis until the patient is again examined a few months later. If, on the second examination, the results of the tests are worse than formerly, then the prognosis is decidedly bad, since the indications are that a rapidly progressive lesion is at work. If the tests show the same or better results than were obtained at the previous examination, then a correspondingly good prognosis may be given, provided the cardiac condition itself is not getting much worse. Naturally, such possible accidents as a cerebral hæmorrhage or cerebral infarct must be taken into account. I have, however, been struck by the fact that patients, even those suffering from marked arterio-sclerosis and cardiac change, often live for many years when the kidneys are not markedly involved.

---

[1] Modern Methods in the Diagnosis and Treatment of Renal Disease. Constable and Co., London.

The Relation of Albuminuria to Nephritis.

The days are now passed when albuminuria was generally taken as a fairly definite indication of renal disease, but it is not yet fully realised that the presence of some protein in the urine is a common condition, while nephritis, on the whole, is a comparatively rare disease. There is a good deal of evidence, chiefly based on the results of examination of soldiers in the late war, that from 3 to 5 per cent. of healthy individuals show some degree of albuminuria. The presence of protein in the urine cannot therefore per se be taken as evidence of nephritis. The appearance of albuminuria in young people under the age of 20 or so—the so-called functional or adolescent albuminuria—is now accepted as a definite entity having no relation whatever to renal disease, but it is not so well known that albuminuria is, perhaps, nearly equally common in adults and elderly people whose kidneys are quite normal for their age. Even the presence of a few hyaline casts is not necessarily of much significance, so that examination of the urine in such cases is not very helpful. Again, it is quite certain that the albuminuria associated with a definite attack of acute nephritis may persist through life, and yet the kidneys may show no evidence of deficient function. It is, therefore, not good practice to diagnose chronic nephritis in an individual with albuminuria simply because the albuminuria is associated with a history of acute nephritis many years before. Certain of these subjects are the victims of sclerosed patches in the renal substance, but frequently no signs of progressive disease can be ascertained, and on testing it may be found that the kidneys are functioning excellently. It is equally true that the urine may be quite free from protein in chronic nephritis of all grades of severity; indeed, it is not uncommon to see a patient dying from uræmia without any protein having been found in the urine.

In the routine examination of several thousands of patients suffering from the effects of war nephritis nearly 5 per cent. showed very definite evidence of chronic nephritis without any albuminuria. By clinical means alone it is frequently quite impossible to say whether or not albuminuria indicates the presence of nephritis, and the question at once arises whether it is possible to do this by means sufficiently simple to be employed by the practitioner who does not possess special facilities. In many cases the question can be answered by the use of the urea-concentration test as fully as it is possible to answer it by the most complicated tests. If, for instance, the urine is found to contain 3 to 4 per cent. of urea, as is often the case after the test is carried out, it may be taken for granted that all other tests will simply corroborate this one, and that as far as it is possible to say by any means at our disposal to-day, the kidneys are efficient. Of course, no test that has ever been evolved can give an indication of very early slight pathological changes in the kidneys, but the urea-concentration test probably approaches more nearly to this ideal than does any other test, since its basic principle depends on giving the kidneys more work to do and ascertaining how they can perform this work. In other words, it is somewhat similar to the exercise test in cardiac disease, and quite as simple. In conjunction with the clinical evidence this urea test will frequently help to settle quite definitely whether a patient with albuminuria has defective kidneys or not.

Treatment of Functional Albuminuria.

When the medical attendant is satisfied that a patient with albuminuria is not suffering from renal disease, it frequently becomes necessary to endeavour to stop the albuminuria. It is unfortunate that many of our public bodies who examine youths for entrance to various Services very often refuse to admit patients suffering from albuminuria, even though examination shows that the condition is of no importance. Various methods have been adopted with a view to getting rid of the condition, but in my experience the simple method of keeping the patient in bed, or at any rate at rest, for a day or two, and giving him large doses of calcium lactate and sodium bicarbonate (say 30 gr. of each three times a day) generally removes the condition at least for a time. When this simple treatment results in a disappearance of the protein it affords additional proof that the condition in the kidneys is not an organic one. It is, of course, unfortunate that many insurance companies look askance at subjects with albuminuria, but no doubt, in the future, when the value of renal tests is more generally appreciated, this will be remedied. Even now, in some quarters, signs of a change in this direction are beginning to appear. In general, it is not a very difficult problem to decide by the use of modern methods whether a case of albuminuria is dependent on nephritis or is simply an accidental occurrence.

THE PANEL CRISIS.

NATIONAL HEALTH INSURANCE FUNDS: TRADE-UNION AND LABOUR PARTY VIEW.

INFORMATION concerning the general financial position under the National Health Insurance Acts is embodied in Part III. of the report lately issued by the Joint Advisory Committee on Public Health, and accepted by the Trades Union Congress General Council and the National Executive of the Labour Party. Attention is given to "various funds in connexion with National Health Insurance which, although constituted of, or earned by, moneys which primarily or actually belong to approved societies, are funds in respect of which the societies themselves are permitted no direct control, and in which societies are officially regarded as having little (if any) financial interest." These include (inter alia): (*a*) the account of moneys permanently or temporarily invested for approved societies (including reserve values redeemed) and the interest earned thereby; (*b*) the reserve suspense fund; (*c*) the unclaimed stamp sales account; (*d*) central fund; (*e*) the deposit contributors' fund; (*f*) the reserve values (apportionment) account.

(*a*) *Interest on Moneys Invested for Approved Societies.*

Up to Dec. 31st, 1922, the Ministry had earned in interest and profits about £3,000,000 over and above the sums which they had credited to societies in respect of the same period, and after deducting losses incurred of £1,300,000 on pre-war investments, there still remained over £1,600,000 clear profit. On the investments as they stood at Dec. 31st, 1922, the Ministry would continue to make a profit of about £300,000 annually after crediting societies with a lower rate of interest than the Ministry in fact earn with the societies' funds; and as additional investments amount to about 1¾ million pounds annually, this profit would constantly increase.

(*b*) *Reserve Suspense Fund.*

The main purpose of this fund is to create reserve values in a case where a person ceases to be insured otherwise than through death. Should the person re-enter insurance, a reserve value appropriate to his or her age is debited to the reserve suspense fund and credited to the society which he or she joins. A large number of persons who go out of insurance on marriage or change of status never re-enter employment, and no claim is made upon the reserve suspense fund in respect of them; the sum transferred by societies to such fund remain therein, and the fund accumulates at interest. As recently as 1920 the Government Actuary expressed the view that the surpluses in the reserve suspense fund would be such as "materially" to shorten the period fixed for the redemption of reserve values amounting to £66,000,000 if utilised for that purpose. Such surpluses may, in fact, be applied to other purposes, such as medical benefit.

(c) *Unclaimed Stamp Sales Account.*

From the commencement of National Health Insurance a fund of hitherto unknown dimensions has accumulated, represented by the difference in the value of health insurance stamps sold by the Government and the value of that proportion of the same stamps placed upon insurance cards surrendered to the Ministry of Health by the approved societies. The difference represents lost or spoiled stamps plus the value of stamps placed upon cards by employers whose employees either destroyed them or have never troubled to surrender them to societies. In the early days of the Act this latter feature was, no doubt, greater than it is to-day, but the income lost annually to societies generally by the apathy of their members is still considerable. Between July, 1912, and December, 1922, the difference between health stamps sold and those credited to approved societies and others approached five million pounds sterling, interest alone amounting to over £750,000.

(d) *Central Fund.*

This fund, admittedly over £2,000,000 at the end of 1921, was originally formed to assist approved societies who were in deficiency at valuation through no fault of their own. It was maintained by a deduction from the weekly contribution paid by the insured. In 1921, however, it was considered that the fund was large enough for its purpose and the sum theretofore taken from the insured persons' contribution for the purpose was utilised to provide the 5*d.* before referred to as a temporary addition to the approved societies' administration allowance. In 1922 one-third of the sum by which the Treasury was relieved (under the Geddes recommendations) to Dec. 31st, 1923, in respect of the grant for medical benefit, was directed by Parliament to be paid out of the central fund. Very few claims, amounting to not more than £11,000 in all, were made upon the fund at the first valuation. Possibly a slightly increased call may be made upon it at the second valuation now proceeding, but the fund accumulates at interest (about £80,000 per annum), and will in that way recover its losses.

(e) *Deposit Contributors' Fund.*

The position of a deposit contributor is that contributions paid by, or in respect of, him are alone available to him when in need of benefit. Like members of approved societies, however, deposit contributors drop out of insurance and are only entitled in two events (death or emigration) to receive a portion (not more than one-half) of the sum standing to their credit. Some portion, if not the whole, of the sums left in the Deposit Contributors' Fund by contributors who have ceased to be insured is transferred to the Reserve Suspense Account; up to the end of 1918 some £600,000 had been so transferred. At the end of 1920 this had been increased to £1,000,000, and at the end of 1923 will probably exceed £1,500,000.

(f) *Reserve Values (Apportionment) Account.*

It was assumed in 1911 that through the sinking fund provided out of the weekly contributions under the Act, and accumulated at 3 per cent. interest, would redeem—i.e., turn into actual cash—the £66,000,000 of initial reserve values credited to societies within about 20 years. The sinking fund has, however, already been raided on several occasions during the past ten years, and as a result the date of redemption has been postponed to about 1955. There would seem to be little reason for concern about the actual date of redemption so long as approved societies are credited annually with interest at 3 per cent. out of the sinking fund upon the amount of cash ultimately payable to them, and no valid objection to another postponement of the date of redemption if for the benefit of the present generation of insured persons a further sum can be set free each year for medical benefit.

Certain other funds administered centrally by the Ministry, such as the Army and Navy Insurance Fund, the Exempt Persons Fund, &c., would doubtless be found upon examination to possess surpluses over and above those required for the performance of the objects for which the funds exist. It is thus possible to find within the ambit of National Health Insurance unallocated funds constituted out of the present weekly contribution sufficient to secure not only a continuance of the existing service, but also of various improvements, at a cost which would not deprive the insured of benefit advantages which they at present possess.

A review of the financial position of National Health Insurance obtained by the British Medical Association during the course of, but independently of, this consideration of the subject, confirms the views expressed above, and will shortly be published.

Position of Approved Societies at the Second Valuation.

In this connexion the report states briefly as follows:—We ought not to pass from the region of finance without a few general observations on the position of approved societies at the second valuation. It has been clearly demonstrated to us that societies generally will have suffered severe loss during the past quinquennium as the result (*a*) of a serious reduction in the number of contributions paid owing to unemployment; (*b*) of paying minimum cash benefits to unemployed members without (at any rate for a period) receiving the contribution necessary to sustain such payments; (*c*) of bearing from April, 1922, to December, 1923, two-thirds of the Treasury grant for medical benefit which came to an end with the Geddes Report. Had those losses—due to economic conditions which have obtained for over two years and still obtain—not been present, the financial position of approved societies would undoubtedly have been rosy, for certain "profits" even now exist as a partial set-off to these losses. These profits, briefly stated, are: (1) A continued sickness incidence below the expected; (2) the added advantage derived therefrom since 1920, when the normal rates of benefit were increased 50 per cent., and since 1921, when further cash benefits were provided out of valuation surplus—both on the basis of the original expectancy as regards claims; (3) the addition to the benefit fund of the contingency money retained in hand in 1918; (4) a continuance of the improved interest-earning power of money above that anticipated in 1911; (5) gains on the maturity, sale, or exchange of wartime issues of Government stock; (6) balances unexpended of sums set apart for treatment benefits under first valuation schemes which have not been in full operation during the whole period; (7) interest earned on accruing surpluses.

Of insurance finance it may be true to say that both as regards mortality and sickness the national rates have improved since the 1911 Act was passed. The former acts adversely upon sickness insurance, the latter favourably. It would, however, appear that disablement benefit—which was expected to reach its apogee in ten years—is still on the up-grade, and the forecast of the Ryan Committee, set up by the Treasury in 1914, that this particular benefit might prove in the end more costly than was anticipated in 1911, especially as regards women, will probably be realised.

The Committee think that on the whole it is wise not to assume that societies generally will be able to give, after the second valuation, any greater benefits than they now give as the result of the first, and that to achieve this result it may be necessary to indent upon that portion of the surplus set aside by the Government valuer at the first valuation as "indisposable." The second valuation is to be performed in two sections, the smaller societies being valued as at the end of 1922 and the larger as at the end of 1923.

THE SYSTEM OF PAYMENT BY ATTENDANCE.

Without affecting the constitution of the central fund or pool out of which insurance practitioners as a whole are paid, various methods have been suggested for individual distribution. Under the Acts this is essentially a matter to be determined by the doctors themselves in any area. The capitation method is well known, and its drawbacks, real or imagined, have been set out faithfully enough. Sir John Collie, n a letter to the press, has revived an old proposal to pay by the number of cases treated in the year. The Manchester and Salford area elected from the first to have a system of payment by attendance, and we are indebted to Dr. Stanley Hodgson for the following exposition of the psychological working of this system in Salford, where it has been most highly developed:—

It may, at first glance, be considered extraordinary that there should be any far-reaching differences in the results accruing from the payment of a professional man by a salary depending only on the number of persons for whom he accepts liability for treatment and from the payment for the actual services rendered—and still more extraordinary when it is premised that the total payment in the latter case must be the same as would be made were the former method in operation. That there are differences is well known, and the supporters of the "payment per attendance" method maintain that these differences are fundamental and indeed vital. The underlying factor is purely psychological, and in discussing the claims of the two methods there is usually a tendency to consider only remote psychological effects and ignore the immediate ones. And yet in the very great majority of persons it is the immediate effect that colours the outlook, however much the remote effect may be desired.

Capitation and Attendance Systems Contrasted.

Under a capitation system it is to the advantage of a medical practitioner to keep his clients healthy, since he will be paid the same amount whether they are sick or well. Under the attendance system it will be of equal importance to prolong illnesses, since the greater the attendance the greater the payment. These are the psychological influences supposed to bear upon the practitioner and mould his conduct towards his insured patients. It is easy to understand that advanced thinkers in the friendly society world accept these statements as cogent and valid, but it is difficult to understand how any medical man, whose profession demands that he shall use his brains, can fail to see their obvious fallacies.

Let us examine the first statement. How can a medical man keep his patients in health? Clearly he must exercise an unremitting vigilance over their every action; he must inspect every article of diet before it is cooked and again before it is consumed. He must direct the putting on and putting off of clothing; he must personally supervise the work of his client; in fact, he must combine the rôles of parent, tutor, and medical attendant. He would find it difficult to succeed were he to devote the whole of his time to *one* patient; more than one makes it at once absurd. The first premise must be altered, therefore, to the practical formula that it will be to the pecuniary advantage of a practitioner to *attend* his patients as rarely as possible. And this is the immediate psychological effect of the capitation system. Fortunately the great bulk of the medical profession realises that the practice of medicine entails the maintenance of high ideals, and the pecuniary benefit of suppressed attentions is not allowed to weigh with the individual practitioner; but, however honourably he may fulfil his obligations, he cannot avoid the mental effect of the knowledge that his income is *not* affected by the amount of work that he does.

Under the attendance system the practitioner is supposed to be benefited financially by a prolongation of illnesses. Here, again, we have to ask how this can be achieved. Frankly it is impossible. The most he could do would be to insist that the patient was not as well as he imagined himself to be and to demand prolonged convalescence. Unless the patient were to aid and abet the doctor—were, in fact, a malingerer—this method would fail for economic reasons. There remains, then, for the dishonest medical man only the method of too frequent visits and consultations. And this is a real danger in unrestricted payment per attendance. But it was foreseen at the onset by the protagonists of the attendance method, the Salford Panel Committee, who laid down a criterion of attendance. They declared a standard and that standard was the amount of attendance that an average practitioner would give to a private patient in a similar class of life, with the further condition that the attendance should satisfy the patient both in adequacy and in moderation. That is to say, the patient should feel that he wished to continue the relations of patient and doctor and was prepared to pay the bill. The committee next proceeded to express this standard in practical terms, and the first method adopted was to take the grand average of attendances on the whole of the sick by the whole of the doctors. This would mean, for example, that if in a given period, say one month, 100,000 sick had received 300,000 attendances, there would be a grand average of three attendances per patient attended. Each individual practitioner had then his own particular average ascertained for the same period, and it was found that the men fell roughly into two categories—namely, those whose average attendances were consistently moderate and those who were consistently high. As each patient was only worth a fixed sum to the pool from which payments were made, and as the grand total of attendances was far too great to allow of even a very modest fee for each item, the "above-average" practitioners were reduced to the general average before they were allowed to rank for payment. The "below-average" were not raised to the general average.

The Low-average "Bogey."

After a time it was clear to the committee that the below-average contingent contained most of the men of best repute and that they were suffering pecuniarily because the large attendances of the others raised the average cost. This necessarily followed the fact that the pool was insufficient to pay the agreed fee for visit, attendance, &c., on the whole general average. A "bogey" was then set up, based on the performances of the admittedly good low-average men, and individual averages were then reduced to this bogey. As payments were monthly a new source of inequity arose from the action, or possible action, of those who encouraged a patient to put in an appearance, if only once, in the succeeding month. Such action would tend to lower that doctor's particular average and thus give him an unjustifiable "pull" on the funds. Repetition factors were then determined—i.e., the number of times the same patient appeared on the year's monthly sheets. These factors gave valuable information and revealed the not surprising fact that the low-average attendance men had also low repetition factors. A further source of possible unfairness lay in the treatment, as regards payment, of what were termed "part-time patients," that is, patients who went to two or more doctors during the current year as contrasted with "whole-time patients" who remained under the same doctor for the whole period. Satisfactory methods were adopted for equalising these inequalities, and what is more, the whole process of adjustment was simplified so that it could be carried out automatically by unskilled clerical labour.

Mental Attitude of Practitioner Participating in Attendance System.

The mental attitude of the insurance practitioner under the attendance system as regards his patient became, therefore, the following complex. First there was the feeling of satisfaction. Every patient that he saw represented a fee. This exactly corresponded to the attitude that arose in private practice and is the most valuable adjunct to satisfactory treatment. Secondly, he would have the conflicting ideas, "If I do not give this patient what he considers sufficient attention, he may, under the right of free choice, immediately change his doctor, whereas if my attention on him is considered by the committee to be excessive I shall have done my work for nothing."

Unable to set up any artificial standard, he allows the two ideas to cancel themselves out and treats his patient just as the necessity arises. There remains to him, therefore, only the emotion of pleasure at the anticipation of reward for work done, and this emotion, colouring all his relations with his patient, is responsible for the smoothness with which the system runs and the satisfaction of those who run it. It is all a question of psychology, and the opponents of payment per attendance lamentably ignore this potent factor in all their calculations. In practice the practitioner who treats his insured patients just as he would treat them were they private patients of the same class finds that his payments remain singularly stable and that he loses no more than those lost amongst an equal number of private patients.

RESIGNATIONS FROM THE PANEL.

The total number of resignations of insurance practitioners received by the secretaries of panel committees throughout the country was as follows :—

	Areas.	Number on the panel.	Resignations— Number.	Per-centage.
England	127	.. 16,356	.. 15,460	.. 94·5
Wales	17	.. 1,157	.. 1,086	.. 96·3
Scotland ..	47	.. 2,413	.. 2,323	.. 93·9
Total ..	191	.. 19,926	.. 18,869	.. 94·7

Information was received from all the areas. In the case of Scotland the Highlands and Islands are not included.

RECORD OF A RURAL PANEL.

We have been asked what is the normal experience of rural panel practice in regard to the number of patients attended during the year, and the number of attendances at the surgery and at the house. No body of figures is available, although certain returns have been asked for and obtained by the Insurance Acts Committee of the British Medical Association. The time spent in entering daily attendances and visits amounts in the course of the year to no trifle, taken from the rural practitioner's already scanty leisure. We have, however, had the advantage of investigating the details of a practice in a rural district where minute records have been kept by two doctors in partnership. The partners live in the same village, the practice extending up to eight miles in various directions, and panel practice accounting for about one-quarter of the gross receipts. The records for 1921 and 1922 are as follow :—

	1921.	1922.
Number of patients on panel	1494	.. 1429
,, ,, ill during year ..	516	.. 551
,, attendances at surgery ..	4037	.. 4100
,, visits paid at house	1504	.. 2259
Cards removed during the year	156	.. 167
Total remuneration received, including mileage and dispensing fees	£1250	.. £1090

With regard to the cards removed during the year, it should be added that the majority of these patients received visits which are not counted in the list as given above. The running motor-car expenses of the partnership, excluding capital outlay or redemption, amounted to £700 to £900 a year, and the full-time services of a dispenser were required.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The Supply of Insulin.

IN a letter to the Dublin daily press Prof. T. G. Moorhead draws attention to the difficulty in providing insulin for poor patients. He points out that since the discovery of the therapeutic powers of insulin, the clinical hospitals have been besieged by patients clamouring for treatment. Prof. Moorhead would like to see a special "Insulin Fund" started to help poor patients both during their stay in hospital and subsequently. But, if it should prove that voluntary subscribers were either unwilling or unable to help, so long as the State was willing to pay for the cure of venereal disease, it should also help in providing the cost of the remedy for a disease which is a misfortune, and not a fault.

The Red Cross on Motor-Cars.

For some months past the continued use of the Red Cross on motor-cars in Ireland has given rise to criticism. Last winter and in the preceding years, when hostilities were still going on, the use of the Red Cross was, no doubt, not only a convenience but a protection. Of late, however, it has been no longer needed, and it was suggested that its continuous use savoured of unnecessary advertisement. Last week the Joint Committee of the British Red Cross Society and of the Order of St. John of Jerusalem gave warning that no more Red Cross slips would be issued by them, and medical men were asked to remove these slips from their cars as there was now no necessity for their use. It is to be hoped that the advice will be followed. The labelling of doctors as such by the wearing of conspicuous marks in normal times is without justification.

Death of Dr. Wallace Beatty.

The death of Dr. Wallace Beatty, honorary professor of dermatology in the University of Dublin, occurred on Nov. 8th at his residence in Dublin. He was in his seventieth year and for the past six or eight months had been in unsatisfactory health. Dr. Beatty was educated at Dungannon Royal School and at Trinity College, Dublin. In the latter he won scholarships both in classics and in medical subjects, and he represented the College on the football field. He obtained his medical qualifications in 1879 and became a Fellow of the Royal College of Physicians of Ireland in 1887. He was elected a physician to the Adelaide Hospital and for many years practised general medicine though always keeping a special interest in diseases of the skin. In middle life he began to suffer from deafness, which gradually made the work of a general physician more difficult, and some 20 years ago he decided to confine his work to dermatology. He contributed many articles and reports dealing with this subject to the special journals. Only last year he published a small manual of diseases of the skin, which in its clarity and precision leaves nothing to be desired. It consisted mainly of the lectures he was in the habit of giving to visitors to his dispensary at the Adelaide Hospital. The death of Dr. Beatty removes a serious and gifted worker in the field of dermatology, and also deprives the medical profession of one of its most loved and respected members—modest, unassuming, and courteous.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Insurance against Sickness in Hungary.

THE Hungarian Minister of Public Welfare has under consideration a projected law relating to reform in the workers' insurance scheme. The new proposals, if accepted, will mark a true reform, inasmuch as insurance will then be extended to all classes, irrespective of financial or social status. The Hungarian medical journals oppose the innovation on the grounds (1) that private practice by physicians will be practically abolished, and (2) that it is too extreme a socialistic measure, in a country which is one of the most conservative of middle Europe. "We have no doubt," says the *Magyar Orvos* (Hungarian Physician) "that the Minister was guided by socialistic principles; but can one call a line of action socialistic which, while conferring equal benefits on rich and poor alike, at the same time despoils the medical profession of its chief source of income? Who is going to profit? Certainly not those to whom the Minister wishes to render good service."

Sick and Crippled Children: A Grave Outlook.

The annual meeting of the Hungarian Medico-Pedagogical Society, held last month, was attended by many medical men, in addition to judges, teachers, and parents. All who spoke were unanimous in stating that the lowered standards of public health and of the physical fitness of the individual, with all their attendant distress, were due to the general poverty of the land. Thousands of children, and adults also, were crippled mentally and physically. All of these, it was held, could be restored to health, or at least rendered capable of earning a living, if adequate and free treatment were provided. One of the speakers went so far as to reproach the Government with spending more on horse-races than on the care of destitute children. Dr. Paul Ranschburg, neurologist, gave an address on the ways and means of conducting an effective campaign against the prevailing distress. He stated that the number of children who were in some way affected, either blind, deaf and dumb, crippled, or mentally and morally defective, exceeded 100,000. In the majority of cases, he stated, these defects were curable. Only a fraction of the moral defects had a pathological origin, by far the greater proportion were due to poverty and misery. He added, further, that in the light of modern knowledge on the functions of the endocrine glands, greater attention should be paid to the application of gland therapeutics in treating many mental and moral deficiencies. Mr. Daniel Geguss discussed the morals of the streets. As magistrate of the court for juvenile criminals, he had had the opportunity of studying the social causes of destitution among the youth. Girls went on the streets to escape from dirty and overcrowded lodgings, cold, sickness, and starvation. Parents in so many cases were unable to provide for their offspring, and thousands were driven to seek a livelihood in prostitution. Was it to be wondered at that 80–90 per cent. of such girls were diseased? The police refrained from controlling prostitutes, or of having them medically examined, as there was no accommodation available in the hospitals. Such problems called for most serious consideration; the remedy lay, the speaker asserted, in improving the social code, in providing adequate housing accommodation, and in educating the masses. The proscribing of immoral literature, the exclusion of all children under 16 years of age from cinemas, and the prohibition of juvenile employment were all imperative measures if sane and happy children were to be reared.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Rear Admiral J. Shand is placed on the Ret. List at own request.

ROYAL NAVAL VOLUNTEER RESERVE.

Temp. Surg. Lt. (D.) G. P. Monk is transferred to Permt. List as Surg. Lt. (D.).

ROYAL ARMY MEDICAL CORPS.

Maj. D. P. Watson is appointed Dep. Asst. Dir.-Gen., vice Maj. and Bt. Lt.-Col. H. V. Bagshaw.

Col. B. Watts, late R.A.M.C., retires on ret. pay.

Maj. N. E. Dunkerton relinquishes the temp. rank of Lt.-Col.

REGULAR ARMY RESERVE OF OFFICERS.

Col. J. D. Ferguson, late R.A.M.C., having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

MILITIA.

Capt. R. M. Beath to be Maj.

TERRITORIAL ARMY RESERVE.

Lt.-Col. A. M. Martin resigns his commn. and retains the rank of Lt.-Col.

ROYAL AIR FORCE.

Medical Branch: Flight Lt. B. F. Beatson (Capt., I.M.S.) is granted a permanent commission.

The undermentioned Flying Officers are promoted to the rank of Flight Lt.: T. J. D. Atteridge, E. C. K. H. Foreman, and W. J. G. Walker.

INDIAN MEDICAL SERVICE.

Col. C. H. Bowle-Evans to be Major-General.

Obituary.

THOMAS HENRY GREEN, M.D., F.R.C.P. LOND.,

CONSULTING PHYSICIAN TO THE CHARING CROSS AND BROMPTON HOSPITALS.

WE have already announced the death of Thomas Henry Green, consulting physician and emeritus lecturer on clinical medicine to Charing Cross Hospital and consulting physician to the Hospital for Diseases of the Chest, Brompton, which occurred at his residence at St. Albans on Nov. 5th last in the eighty-second year of his age.

Dr. Green, who for many years was recognised as a leading authority on diseases of the lungs, and whose text-book on pathology has well served so many students, was educated at University College, London, where he graduated as M.R.C.S. in 1864, taking the degree of M.B. Lond. in the following year. After holding the usual residential appointments at University College Hospital, he was elected physician to the North-West London Free Dispensary for Sick Children and later medical registrar to the Children's Hospital Great Ormond-street. He proceeded to the M.D. degree in 1866 and was appointed lecturer on pathology at the Charing Cross Hospital, being elected assistant physician in 1869. He was already on the staff of the Hospital for Diseases of the Chest at Brompton, and throughout his long professional life he was associated with the two institutions, being at his death consulting physician to both. He was esteemed by his colleagues at each hospital as a highly equipped physician, for the care that he took both in making the diagnosis and allotting the proper treatment was boundless.

"It was a fortunate day in the history of Charing Cross Hospital," writes an old colleague, "when Thomas Henry Green joined its staff. He brought with him the spirit, example, and teaching of two of the masters in medicine of the time: Virchow, the greatest living pathologist; and Jenner, the leading clinician then in England. Fresh from Berlin after University College, young but by temperament calm, earnest, judicially minded, he introduced order and interest with precision and scientific methods into the post-mortem room for the first time, and order and true clinical observation into the out-patient department. He invited the students to the post-mortem room, and his descriptions of the conditions found were regarded as a marvel of lucidity and exposition. History reported that before Green's time post-mortem examinations stopped short at the discovery of 'the cause of death'; and his first necropsy was witnessed with amazement. Along with these methods he brought the doctrine of the cell and cellular pathology, the basis of his lectures and of his text-book on Pathology and Morbid Anatomy which was to become rapidly famous. His lectures on pathology were delivered with an enthusiasm and precision which carried conviction to students and rendered reference to text-books unnecessary.

"In the examination, treatment, and general care of his patients Green exercised the closest attention personally, and he exacted the like from his resident staff. Thus: 'You will sit up to-night with this patient' he said to a house physician, 'since sister cannot tell me how he slept.' His visits to the wards were strictly regulated; on fixed days to the patients with his house physician, on other days to meet his students. His bedside teaching was closely modelled on that of Jenner—precise, sententious, dogmatic, and eminently practical. His regular clinical lectures (he never accepted the chair of medicine) were planned and timed with the same precision—consisting of an annual series which the students learned to anticipate but which they valued none the less—his favourite subjects being pneumonia, typhoid fever, tuberculosis, and cardiac failure. Green's instruction was never lost or forgotten, as many of his hearers still testify. Or he would give a lecture of half an hour on a subject illustrated in an individual case—such as indigestion, dyspnœa, or paralysis—a homily which served his pupils immediately as preparation for examinations and was a sure guide in practice in later years. Then the students were dismissed instead of ' going round ' with him, for he held that tit-bits of clinical instruction were thrown away. He liked to adjust the various noteworthy points in a case in proper sequence and show the bearing of them to each other. Equal order and orderliness marked his work at Brompton. There he sat alone in the out-patient room or went round the wards with his resident officers, and requested visitors desirous of following his practice to meet him at Charing Cross.

" Apart from his wards and his own immediate offices, Green did not engage in the work of Charing Cross Hospital and its medical school, which were, in his earlier years there, passing from relative dullness and obscurity into a period of success as a teaching centre with fresh ideals. To this success Green's work and his name contributed largely, but he never was more than an ordinary member of the different committees. He fulfilled the duties of his posts unfailingly and in full measure, but he appeared to stop there ; to spend no time in general colloquial discussions. Not that he was unsociable. Personally Green was by temperament reserved, not to say distant, in manner, habitually somewhat formal when receiving his friends and when bidding them good-bye. Indeed, he was in every respect precise, faultlessly trim in dress, punctilious, brief, definite, and exact, yet tactful in giving his opinion and advice to doctors, patients, and patients' friends. But in social intercourse and entertainment he was always bright, interesting, and full of enjoyment ; nowhere more so than at the delightful old-time dinners of the Brompton staff. His pupils became his firm friends, and he a valued friend to them. Many of them still testify to the precious lessons they learnt at his side."

Upon his special subject Dr. Green was a clear and informative writer, good examples of his work being furnished by his clinical lectures on phthisis in our own columns, while he was a contributor on the same and allied subjects to the *British Medical Journal* and to the *Medical Times and Gazette*. Other papers by him were published in the Transactions of the Pathological Society and the Clinical Society and revealed the same qualities, in that the advice given was always clear and of a practical bearing. In Quain's " Dictionary of Medicine " he wrote the article on Inflammation of the Lungs, and he was also the author of a volume on the Pathology of Pulmonary Consumption. But Green will be best remembered by his " Manual of Pathology," the seventh edition of which appeared as recently as this year, being revised and enlarged by Dr. W. C. Bosanquet and Dr. G. S. Wilson. Few medical textbooks can have enjoyed so successful a career as this one, for it has been in demand among medical students for over half a century. Year by year successive editors have been able to modernise it without robbing it of its original and distinguishing features. Thus it has always remained a model of a text-book.

WILLIAM HARRISON CRIPPS, F.R.C.S. ENG.

THE death occurred at his London residence on Nov. 8th of Mr. Harrison Cripps, consulting surgeon to St. Bartholomew's Hospital, and well-known also in the world of business as chairman of the Metropolitan Electric Supply Company.

William Harrison Cripps was the son of Henry William Cripps, Q.C., Recorder of Lichfield, and the brother of Lord Parmoor, and received his medical education at St. Bartholomew's Hospital, with which institution he was associated throughout the whole of his professional life. He qualified as F.R.C.S. in 1875, and was elected assistant surgeon to the hospital in 1883, becoming surgeon in 1902 in succession to Mr. Willett, so that, as has so often happened at St. Bartholomew's Hospital, he was a member of the staff for 20 years before he obtained a charge of wards. Happily a great opportunity for practice was furnished by his selection as surgeon to the gynæcological department. His gynæcological work is well known, but his chief professional reputation, as well as a large private practice, depended upon his skill in diagnosing and treating affections of the rectum. As long ago as 1876 he won the Jacksonian Prize of the Royal College of Surgeons of England for an essay on the treatment of cancer of the rectum. As a volume this essay went through several editions, the possibility of curing or relieving the patient by excision being closely considered, and from the date of publication he became a recognised authority on diseases of the rectum and anus.

Harrison Cripps wrote also a treatise upon abdominal surgery and ovariotomy, while he contributed valuable papers on both of his special subjects to the St. Bartholomew's Hospital Reports and to the columns of THE LANCET. Other papers, which he published in the Transactions of the Obstetrical Society and those of the Pathological Society, dealt with malformations of the rectum and the minute anatomy of certain rectal growths. He contributed also to Heath's " Dictionary of Practical Surgery " and Holmes's " System of Surgery " ; his selection to assist in these well-known works being an indication of how high he stood in the opinion of the professional leaders as an exponent of the pathology and surgical technique of the difficult conditions with which he had made himself familiar. In the Royal College of Surgeons of England Harrison Cripps played an important part, for he was elected to the Council in 1908 and was a member of that body for a period of 12 years, serving for two years as Vice-President.

Sir D'Arcy Power has sent us the following appreciation :—

" A study of the careers of the Fellows of the Royal College of Surgeons of England shows that many hospital surgeons have been such good organisers and fine administrators as to have excelled in spheres widely divergent from those they had mapped out for themselves to conquer. The qualities which make a first-rate surgeon are identical with those required by a successful man of business, to take only a single example. Harrison Cripps was an outstanding instance and he used his talent in a double capacity with equal advantage. On his mother's side he came of a medical family long established in Gloucestershire, whilst his father who came of the same stock was a successful member of the Parliamentary bar. The most distinguished member of the Cripps and Lawrence families was Sir William Lawrence, surgeon to St. Bartholomew's Hospital from 1813 until 1865, and Cripps was therefore predestined to attach himself to the same school. He soon gave evidence of his ability by gaining the Jacksonian Prize for his essay on cancer of the rectum and its operative treatment, a subject which interested him until the end of his life. Promotion to the teaching and surgical staff soon followed and he obtained practical experience as surgeon to the Great Northern Hospital. He became assistant surgeon at St. Bartholomew's Hospital in 1883, after having previously contested an election in which he was beaten by Mr. W. J. Walsham. As assistant surgeon he remained until 1902, his hospital practice during this long period of waiting being restricted to the three beds allowed him by the courtesy of his senior. In later years he was attached as surgeon to the gynæcological ward of the hospital and he built up for himself a large operative and consulting practice in private. He attended the meetings of the Royal Medical and Chirurgical Society and of the Pathological Society during his early years with considerable assiduity and his contributions showed marked originality. He was amongst the first to advocate the performance of Littre's inguinal colostomy in preference to Amussat's lumbar operation, which was then in common use. But in later years he took no great part in advancing surgery, either by lecturing in the medical school or by undertaking any of the great public lectures at the Royal College of Surgeons.

" I knew nothing of his work as demonstrator of natomy because he had become surgical registrar efore I entered the hospital, but his teaching, like iat of his colleagues, Mr. A. E. Cumberbatch and Mr. V. J. Walsham, must have been good, for there were o failures at what we used to call " the first batch " t the Primary Examination. My personal recollec- ons begin with his teaching in the out-patient epartment, where he was thorough, painstaking, and omewhat of a martinet, for he insisted on regular and unctual attendance from those who elected to serve s his dressers. His teaching was Socratic and was nlivened by sharp showers of caustic wit descending ith equal impartiality on students and patients and elivered in a soft voice with a little click of the tongue hich was either copied from Sir William Lawrence or as an inherited Lawrence trait. I do not remember iat he had at any time an especial regard for isterian methods, at any rate, he did not operate nder the carbolic spray which was then in vogue.

" As a man of business Cripps showed himself articularly capable. Beginning life with very slender sources he early saw the capabilities of electrical iterprise and he gradually bought founders' shares in ie Metropolitan Electric Supply Company. A con- derable portion of the company was eventually urchased by the St. Marylebone Borough Council hen Cripps received the reward of his foresight, whilst the same time he remained as chairman of the iginal company. His knowledge of business was ways placed at the disposal of the College of urgeons whilst he was on the Council and for some ears he was a valued member of the Finance Com- ittee. His business habits sometimes made him a ttle exacting in the matter of fees, for he realised the alue of money and maintained that professional rvices were apt to be inadequately remunerated.

" Cripps was seen at his best as a host whether in s house in Stratford-place, at Abbotsford, or in later ears at Glendaruel in Argyllshire. He loved to have s house full of guests and that he might give the eatest pleasure to the greatest number of his friends was accustomed to invite each for a definite period. ll were welcome, alternative plans were made daily iat all might be amused, and the evenings were nlivened with pleasant talk interspersed with good usic. As he grew older the jibe and sarcasm of his ounger days remained, but the jibe had lost its tterness and the sarcasm had become more human. here remained the courteous host with the polished anners reminiscent of the family tradition of what as befitting a Gloucestershire gentleman."

FRANK STANLEY TINKER, M.B., B.C. Camb.

We regret to announce the death in Devonshire of r. Stanley Tinker. After qualifying in 1911, and olding resident appointments at the Liverpool oyal Infirmary, he was invalided to Switzerland in e spring of 1913 with signs of pulmonary tuber- losis. Having practically recovered after 18 months the Alps, a period which he utilised to make himself miliar with sanatorium treatment and the routine ork of a clinical laboratory, he returned to England take his Cambridge medical degree, and became in ccession school medical officer to the Surrey County ouncil, one of the Surrey county tuberculosis ficers, and medical superintendent of Crooksbury natorium, Farnham. He also translated Cornet's onograph on miliary tuberculosis, and was an active ember of the editorial board of *Tubercle*. At this ne he became interested in municipal workshops r tuberculous patients, and worked out a scheme r the post-sanatorium employment of the con- mptive ex-soldier. These qualifications procured m the appointment of medical superintendent at the arrowmore Hall Tuberculosis Colony, near Chester, here he proved an able administrator as well as nician. Unfortunately an attack of influenza lit up ain his old chest trouble, and he again sought health Switzerland, this time without avail. Tinker ll be missed in the circle of younger tuberculosis lministrators, among whom he was widely esteemed.

Correspondence.

"Audi alteram partem."

THE CENTENARY DINNER: AN INCORRECT RUMOUR.

To the Editor of The Lancet.

Sir,—Much to my surprise I have been informed that there will be no medical women present at The Lancet Centenary Dinner. Can this possibly be correct? I am, Sir, yours faithfully,

Nov. 13th, 1923. M.D.

⁂ It is entirely incorrect, and the circulation of this report has caused great annoyance. Not only are medical women expected, but many have already signified their intention of being present on Nov. 29th at the Hotel Victoria.—Ed. L.

AN IMPETUS IN THE EVOLUTION OF MONOGAMY.

To the Editor of The Lancet.

Sir,—There is no lack of testimony, explicit or implied, in the many articles which have recently appeared in the medical journals that gonorrhœa, whether occurring in the male or female, is a sterilising disease. That capacity to breed is much greater among 10,000 couples who have not suffered from gonorrhœa, whether singly or jointly, than amongst 10,000 who have so suffered, must be a self-evident deduction. This is a matter of massive tendency among large numbers of individuals, not of individual cases; though, of course, individual cases supply this conception of the great sterilising power of gonorrhœa.

One cannot fail to be struck by a condition complementary to gonorrhœal sterility in syphilitic destruction of infant life.

> " There is no disease which is so destructive to infant life . . . an army in numbers to represent the mortality of infant syphilis annually in England and Wales and in ordinary marching order four deep would reach from Aldgate Pump to the Marble Arch, and would take an hour passing any given point; 50 per cent. of syphilitic fœtuses are stillborn; 78 per cent. of those born alive die within the first year, most of the deaths occurring within the first week after birth: and of the remaining 22 per cent. many die in early childhood." (Mr. John Adams, F.R.C.S., M.A.B. annual report, 1922.)

Children which are not even conceived cannot have their teeth set on edge by the sour grape of a sterilising gonorrhœa. Further, since few syphilitic children survive as congenital or hereditary syphilitics but few can present any feature of dentition due to disastrous parental Bacchic feasting. Nature is really very benign in her deep and insistent workings.

Now, a batch of 10,000 syphilitics will contain a very much higher proportion of the persistently promiscuous or polygamous than will 10,000 non-syphilitics. I think this is axiomatic. Further, since a sheep dog produces pups which without any teaching run around a flock of sheep instead of at them, whereas an Irish terrier on first sight of a sheep will start worrying it, and since we have an aphorism, " like father, like son," and are not referring to the pimple on the nose but to deep-set mental characteristics which proclaim themselves in bodily action, there is not much necessity to drive home the argument of hereditary capacity. The inevitable deduction is that gonorrhœa and syphilis are benign and large factors in the evolution of that marital care which, according to Josephus, Moses enjoined on the Israelites,

> " As esteeming it a happy thing that men should be wise in the affairs of wedlock; and that it was profitable both to cities and families that children should be known to be genuine."

It is suggested that syphilis was introduced into Europe only about the year 1500. This, were it a fact, would still leave sufficient time up to date for an enormous impetus in the evolution by natural selection of the monogamous instinct. The statement quoted from the M.A.B. report points to the rapidity and force with which the selection goes on at present in a quite natural and comparatively benign way. The rapidity with which in Plymouth Harbour changes in the crab's carapace took place under a change of environment—namely, a little mud in the water—was well brought out by Prof. Weldon. Some such rapidity of effective action in England and Wales has taken place under syphilis, due allowance being made for the greater period of years of a generation in man and the longer period over which the influence has acted.

We are apt to be shocked by the statement on syphilitic infantile mortality, but its bearing on the problems of life as indicated above would seem to be essentially a factor for consideration whenever infant mortality is mooted. We may shrink from the consideration, but such a gesture would be unworthy.

I am, Sir, yours faithfully,

Gravesend, Nov. 12th, 1923. W. M. Willoughby.

PSYCHO-NEUROTIC SYMPTOMS IN MINERS' NYSTAGMUS.

To the Editor of The Lancet.

Sir,—The first and second reports of the Miners' Nystagmus Committee have not received the attention they deserve. The data collected show that the disease is costing the country £350,000 directly, and £1,000,000 indirectly. In these times an effort should be made to reduce this expenditure. In America, where no compensation is given, little is heard of incapacity due to nystagmus, or, indeed, of the existence of the disease. In Belgium the incidence remains stationary. The same apparently applies to France and Germany. Yet in Great Britain the incidence has increased at an alarming rate, and the cost in compensation has gone up from £13,000 in 1908 to £343,000 in 1920. The reports make it clear that this is due chiefly to the alteration in 1913 of the definition of the disease in the third schedule of the Workmen's Compensation Act, which made the presence of oscillation of the eyeballs unnecessary in the diagnosis. As a result, a large number of men became entitled to compensation whose incapacity was due to psycho-neurotic symptoms. "This group is the one which has increased the reported cases." One would have thought that the Committee would proceed at once to investigate the nature and origin of the psycho-neurosis, and to link it up with the physical signs, of which oscillation of the eyeballs is the chief. But one looks in vain for even a surmise that they may be connected. Does oscillation cause the neurosis, or does the latter induce the oscillation? Is oscillation merely a physical eccentricity, or is it an essential part of the whole abnormal state? An answer to these questions may save the country so much money that pressure should be brought to bear upon the Committee to clear up the mystery. "The standard of physical signs which is in vogue in this country for deciding whether any case should be certified as suffering from miners' nystagmus too readily admits psycho-neurotic cases to whom harm and not benefit accrues from compensation. A stricter standard based on physical signs should be adopted." The ambiguity is perplexing. Does it mean that *all* psycho-neurotic cases are harmed by compensation? Or does it mean that only certain cases are harmed? If the latter, what physical signs of the neurosis are to determine the issue? Photophobia and blinking of the eyelids are not peculiar to miners' nystagmus; they occur commonly in shell shock. The reports show that about a quarter of all underground workers have oscillation of the eyeballs. Severe cases refuse to stop work because they are more comfortable at work. One even plays cricket for his colliery. Would the Committee enforce retirement in these cases, or would they await the development of psycho-neurotic symptoms?

In the introduction to the second report, the Committee state that they "are continuing their work, and have some investigations in view which will deal further with the physiological problems involved." Physiology has done nothing for shell shock. Psychology has done much. Dr. W. H. R. Rivers pointed out the similarity of the symptoms in the war neuroses and miners' nystagmus. Since his death, psychopathology has not been represented in any way on the Committee. It seems reasonable to ask that an expert be appointed at once, having regard to the expenditure annually of a million of money in Great Britain as against nothing in America.

I am, Sir, yours faithfully,

Portsmouth, Nov. 2nd, 1923. W. Inman.

THE ALBUMINURIA OF PREGNANCY.

To the Editor of The Lancet.

Sir,—I have to thank Prof. Frank Cook for the reference, in his letter to The Lancet of Nov. 3rd, to my paper on Unilateral Œdema with Albuminuria. The whole subject of "unirenal" albuminuria is only beginning to receive attention, and it needs further investigation. Prof. Cook agrees with me that the procedure of catheterisation of the ureters cannot be carried out in all suspected cases, and the postural method of investigation adopted in my case may then give valuable information. But its exact significance has yet to be determined. In that case, it seemed to afford something very near to proof of the unilateral origin of the albuminuria. But the inference that the albumin was coming from the left kidney depended upon the presence of left-sided œdema, and also upon the similar case recorded by Ehrmann. In cases in which there is no such œdema it would be difficult from postural observations alone to decide from which of the two kidneys the albumin arises. I would therefore venture to suggest that in all cases in which catheterisation of the ureters demonstrates the origin of an albuminuria from one only of the two kidneys, the observation should be supplemented by postural investigations as suggested in my paper. By this means it might be possible to gain a positive knowledge of the significance of the results so obtained, and eventually perhaps to do away with the necessity of catheterising the ureters.

It is worth noting that in my case standing vertically upright produced practically no increase in the amount of albumin present beforehand, and it may interest Prof. Cook to know that the same was true of a small number of cases of apparently harmless albuminuria in pregnant women kindly placed at my disposal by my colleague, Prof. Thomas Wilson. But in all the cases of orthostatic albuminuria, recorded in my paper in the *Quarterly Journal of Medicine*, the ten minutes' standing test produced a marked and immediate response, except during a period of diuresis. Yet recent observations show that in orthostatic albuminuria the albumin, at any rate sometimes comes from one kidney only. The effect of upright standing is therefore another point that might be worth investigating, if Prof. Cook has the opportunity.

I agree with Mr. R. H. Paramore in his contention that the albuminuria of pregnancy is not likely to be explained on mechanical grounds to any great extent or at any rate that the explanation will be found to apply only to a limited group of cases, of which Prof. Cook's first case is clearly an example. I believe the mechanical cause is too readily invoked as an explanation even of albuminuria of immediately postural origin, and that further investigation will show that many of these cases have a renal pathology. That there are two very different conditions at present included in the group of cases of so-called orthostatic albuminuria I am very sure, but the grounds for their distinction have not yet, I think been fully ascertained.

I am, Sir, yours faithfully,

Birmingham, Nov. 10th, 1923. Jas. W. Russell.

NASAL SINUSITIS IN PHTHISIS.

To the Editor of THE LANCET.

SIR,—Dr. A. L. Yates's paper on the simulation of hthisis by nasal sinusitis is of the useful type that ecognises in addition the *complication* of the first by he second. One or two points call for comment. irstly, there is undoubtedly important literature rior to 1916. Volpillac in an 1898 thesis is cited as aving published cases where treatment of the axillary sinus cured apparent phthisis. Certainly he next year Friedrich[1] mentioned obstinate bron- hitis from sinusitis. The best early paper is, how- ver, that of Du Magny, the first to note the apical tuation of the pulmonary signs, which of course akes confusion with phthisis easy. He did not xplain why the apex especially should suffer, but 1917[2] I suggested this was because of the deficient xpulsive action obtaining at the pulmonary apex, y reason of its extra-thoracic position and the well- nown anatomical peculiarity of its bronchi, factors voked to explain an allied non-tuberculous condi- on. Krönig's apical collapse-induration, that, how- ver, results from dust, not pus, inhalation. Thus e pus from above would invade the lung pretty venly, but be coughed up again from all parts etter than from the apex. Du Magny[3] said that all ppurations of the upper respiratory passages, cluding otitis media, were thus dangerous, and ght years later a pupil of his gave, in the *Revue de oure*, 62 observations in support. Before this, ambert Lack and Mackie had both stated that scharges from an antral empyema might cause gns and symptoms of active phthisis, which cleared p under nasal treatment.

Secondly, Dr. Yates states that posterior ethmoidal d sphenoidal sinusitis had not been met with cept in conjunction with other sinusitis, and that ontal and anterior ethmoidal sinusitis do not mplicate the diagnosis of chest conditions. How- er, on p. 137 of my book, already mentioned, a se is recorded of double, almost exclusively right- ded, sphenoidal sinusitis that I met with at a nsumption hospital. I sent it to Golden-square, here the right sphenoidal sinus was operated on. ven years later no pulmonary or nasal sym- oms. Further, D. McKenzie[4] attributed purulent hmoiditis to ten out of 102 out-patients at a nsumption hospital. I do not want to quote yself again, but if he will do me the honour look he will find evidence of frontal and of hmoidal sinusitis both in patients wrongly diag- sed phthisical, as well as in sputum-positive tients.

Lastly, he will find, too, I think, that "certain nditions so regularly found in the nose and throat patients suffering from pulmonary tuberculosis hen neither laryngeal ulceration nor sinusitis are esent" must be regarded, *not* as results of this sease, but as contributory causes. So well known laryngologist as Moure, of Bordeaux, makes of em a separate non-tuberculous nasal affection, eceding the consumption, constitutional, and even reditary. Too schematic a generalisation, no ubt; but quite certainly nasal obstruction, intra- sal atrophy, and post-nasal catarrh are rife in nsumptives; sinusitis on the whole is vastly less mmon. In conclusion, I would deprecate any cking of nasal sinuses in consumptives with anti- ptics. If, as often, operation is contra-indicated, ntle nasal syringing with an alkaline collunarium, ich the patient learns very easily to do for himself, all that is necessary.

I am, Sir, yours faithfully,

Barnsley, Nov. 3rd, 1923. W. C. RIVERS.

THE LONDON FEVER HOSPITAL.

To the Editor of THE LANCET.

SIR,—The administration and maintenance of the London Fever Hospital, which was the subject of an annotation in THE LANCET of Nov. 10th, presents serious problems to its committee and staff, problems which are largely due to the special nature of the diseases with which the institution has to deal. A personnel which is adequate when the hospital is full is expensive to maintain over periods when the incidence of fevers is slight and at such times there is always the temptation to skeletonise the staff on the ground of economy. Experience has proved that economies of this nature are more than a mistake, they are highly dangerous. The specially trained staff of a fever hospital cannot be disbanded and replaced at a short notice. The danger of an imperfectly trained staff needs no emphasis. It takes time for the basic principles of rigid medical asepsis to become so ingrained that they are part of a nurse's second nature. Moreover newly-imported nurses are very apt to fall victims to the disease they are nursing and themselves to fill up beds which would be available for other cases. Further, from the very nature of its work the hospital must maintain its own laundry and disinfector with trained attendants who can be relied upon to understand their individual responsibilities. It follows that expenses of maintenance must continue to be high although patients dwindle and receipts fall. The pressing problem is to tide over the quiet periods without impairing the efficiency of the hospital. Your annotation is timely and more than welcome. There must be at all times in London and its suburbs sporadic cases of infectious disease, for which the accommodation offered by the London Fever Hospital is particularly adapted and a knowledge of its existence and availability should prove a boon to those who have to deal with such emergencies.

I am, Sir, yours faithfully,

CHARLES R. BOX,
Senior Physician, London Fever Hospital.

Nov. 12th, 1923.

PRIVATE WARDS IN LONDON HOSPITALS.

To the Editor of THE LANCET.

SIR,—May I draw your attention to the fact that this hospital has 25 private wards which are allocated according to the medical needs of the patients who are expected to contribute £3 3*s.* per week, but smaller fees are accepted? The patients are placed under the care of the honorary medical staff who do not receive fees, and the £3 3*s.* represents the total liability of the patient.

I am, Sir, yours faithfully,

H. W. BURLEIGH,
Secretary and General Superintendent,
Hospital for Epilepsy and Paralysis.

Maida Vale, W., Nov. 9th, 1923.

UNIVERSITY OF MANCHESTER.—Lord Crawford was on Nov. 10th installed as Chancellor of the University. Honorary degrees as Doctors of Law were conferred on Dr. J. G. Adami and Sir Arthur Keith.

LANCASHIRE AND THE SPAHLINGER TREATMENT.—The Ministry of Health has withheld permission from the Lancashire Insurance Committee to carry out an investigation into the best way of making this treatment effective in their area. The original proposal of partly subsidising an existing institution fell through owing to technical difficulties. It was then proposed that a sum of £1000 be used to make a preliminary investigation into the practical possibilities of the treatment, but the Ministry does not consider that there is anything within the scope of the Public Health Act allowing the Lancashire Committee to make such an investigation as is proposed. Another suggestion was made that the Minister of Health might exercise certain special powers conferred on him by a schedule in the Act, but the Minister declines to exercise these special powers.

Medical News.

UNIVERSITY OF CAMBRIDGE.—The amended order of examinations for Medical and Surgical Degrees, to be held in December, 1923, is as follows : Of the Third Examination, Part I. (Surgery and Midwifery and Gynæcology) will be held from Dec. 11th to 15th ; Part II. (Principles and Practice of Physic, and Pathology and Pharmacology) on Dec. 12th, 13th, 17th, 18th, 19th, and 20th. The M.Ch. Examination will be held on Dec. 11th, 14th, and 15th.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—An ordinary Council meeting was held on Nov. 8th, with Sir John Bland-Sutton in the chair.—A report was read from the Court of Examiners respecting candidates found qualified for the diploma of Membership, and diplomas were awarded to 170 candidates mentioned in the report.—A report was read from the secretary respecting a candidate, Sybil Grace Mocatta, found qualified for the diploma of Fellow, and a diploma of Fellowship was awarded her.—Dr. J. A. Ormerod was re-elected a member of the Committee of Management.—Mr. C. H. GLASGOW ROYAL MATERNITY HOSPITAL.—At meeting of the Glasgow Women Citizens' Associatio Councillor Mrs. Baird Smith spoke on the subject of th Glasgow Royal Maternity Hospital. In urging the claim of the institution, she said there was comfortable accommodation for 145 patients. Last year 3641 patients wer admitted, and 42,614 were visited in the district. Ther should be added to the hospital a network of maternit homes, in which working women might obtain the perio of rest so valuable after childbirth.

THE LATE DR. FRANK WILDERS MAWBY.—D F. W. Mawby died, after a brief illness, at his home in Littl port, Ely, Cambs, on Sept. 15th, aged 60. Born in Lincol shire, he was educated at Christ's Hospital, and qualifie L.S.A. in 1894 at Guy's Hospital. For the past 30 year Dr. Mawby was in practice at Littleport, where he als held appointments as medical officer of Littleport an Redmere District, Ely Union, and as certifying facto surgeon. His death is regretted by a wide circle of frien in Littleport, for both privately and professionally he wa held in high esteem.

CANADIAN SOCIAL HYGIENE COUNCIL.—A repor of the Medical Committee of the Canadian Social Hygien Council on the Standardisation of the Diagnosis and Treatment of Venereal Diseases has recently been issued by th Department of Public Health at Ottawa. The repor represents the work of a committee of 35 prominent men an women physicians acting under the chairmanship of D E. E. King of Toronto. Final editing of their findings an recommendations was done by Dr. J. J. Heagerty, Chief c the Division of Venereal Disease Control in the Dominio Department of Health, and the report, which is to b widely circulated among medical men in Canada, include the following sections and subsections :—

Medical Research and Laboratory Questions, with subsection dealing with Licensing of Men doing Wassermann Tests an Standardisation of the Methods of Making Wassermann Tests Diagnostic Tests in Syphilis by Demonstration of Treponem Pallidum ; Significance of Wassermann Reaction ; Negativ Wassermann Reaction, with subsections with Precautionar Measures ; Wassermann Tests in Connexion with the Treatmen of Syphilis and Especially as an Evidence of Cure ; Treatmen of Syphilis and Relative Value of Arsenicals and Non-Arsenical with subsection, Eligibility of Marriage ; Minimum Requirements of Treatment ; Treatment of Syphilis, with subsectio dealing with Early Primary Cases, Dark Field ; Wasserman Positive, Secondary, Tertiary, and Latent Syphilis ; Hereditar Syphilis ; Early Preventive Treatment against Syphilis Gonorrhœa ; Treatment of Acute Urethritis ; Complications Gonorrhœa in the Male ; Chronic Gonorrhœa ; Pelvic Gonorrhœ with subsections on Treatment and Standard of Cure ; Treatment of Chronic Gonorrhœa, with subsections on Clinical Examination, Bougie à Boule, Urethroscopy, Blood Examinatio Treatment, and Standard of Cure ; Gonorrhœa in the Adul Female ; Treatment of Gonorrhœa in the Female ; Diagnosis Gonorrhœa in Children, with subsections on its Treatment, th Rationale, Complications, and the Standard of Cure of Vulvo Vaginitis in Children.

The report recommends that "all laboratories, includin university laboratories, doing Wassermann tests, shall b licensed by and under the supervision of the Provincia Board of Health," and urges "private, university, hospita municipal, and provincial laboratories, in the use of thes tests, to adopt recognised methods, so as to approach uniform results for the purposes of comparative study." The personnel of the Medical Committee who prepared the report is as follows :—

Chairman : Dr. E. E. King. Secretary : Dr. C. H. Archibald. Members : Dr. Gordon Bates, Dr. Kendal Bates, Dr. Noble Black, Dr. W. Colling, Dr. M. A. Cox, Dr. H. C. Cruickshank, Dr. H. K. Detweiler, Dr. E. C. Dixon, Dr. W. E. Ferguson, Dr. A. G. Fleming, Dr. Edna Guest, Dr. C. H. Hair, Dr. E. B. Hardy, Dr. F. W. Hassard, Dr. Hewett, Dr G. Howland, Dr. W. Jones, Dr. W. W. Lailey, Dr. Lillian Langstaffe, Dr. J. C. McClelland, Dr. R. A. McComb, Dr. Alex McKay, Dr. F. W. Marlow, Dr. E. A. Morgan, Dr. R. W. Naylor, Dr. H. E. Paul, Dr. Robin Pearse, Dr. G. W. Ross, Dr. Geo. S. Strathy, Dr. E. J. Trow, Dr. W. T. Williams, and Dr. A. I. Willinsky.

The Canadian Social Hygiene Council will follow this report immediately by another on the same subject, prepared specially for the instruction of nurses and for use in all training schools for nurses throughout Canada.

LONDON HOSPITAL MEDICAL COLLEGE. — The Schorstein Memorial Lecture will be delivered by Dr. Gordon Holmes on Dec. 3rd, at 4.15 P.M., in the anatomical theatre of the College. The subject will be Some Symptoms of Cerebral Irritation.

UNIVERSITY COLLEGE HOSPITAL.—A festival dinner will be held at the Savoy Hotel on Nov. 20th, at 7.30 P.M., for the purpose of inaugurating a campaign to raise for University College Hospital a capital sum of £500,000. This campaign is a direct result of, and is necessitated by, the gift made for the purposes of medical education by the Rockefeller Foundation of New York. The Rockefeller gift is to be devoted exclusively to purposes of medical education and research, and the Rockefeller Foundation in making the gift indicated clearly that the maintenance of the additional beds so provided was the responsibility of the British people. Among the speakers at the dinner will be Mr. Winston Churchill. Prince Henry will preside, and will announce at the dinner a list of the subscriptions received towards this special appeal.

THE PASTEUR INSTITUTE OF SOUTHERN INDIA, COONOOR.—In the annual report of the Institute, the director, Lieut.-Colonel J. W. Cornwall, I.M.S., states that the number of patients who underwent a full course of treatment during the year in the Institute was 3375, a decrease of 96 on the previous year's number. The fall in the number was due to the gradual introduction of the scheme for the issue of anti-rabic vaccine to Government headquarter hospitals in the Presidency. With the sanction of the Government it was decided to issue carbolised anti-rabic vaccine to different centres in the Presidency so that persons bitten by animals suspected to be rabid might be treated locally and saved long railway journeys to Coonoor with all the attendant expenses. The scheme is a tentative one, and treatment at the Pasteur Institute is still open to anyone who desires it and can go to Coonoor at his own expense. It is too soon, the report states, to comment on the working of the new scheme. Possibly the chief drawback will be that many persons who are being treated near their homes will not have patience to go through the full course of treatment. A pamphlet entitled Notes on Rabies for Medical Officers, was sent to the superintendents of all the headquarters hospitals, which contained all necessary information under the following headings : (1) The possibilities of infection with the virus of rabies ; (2) methods of dealing with wounds inflicted by rabid animals ; (3) how to deal with a dog which has bitten one or more persons ; (4) indications for anti-rabic treatment ; (5) care of patients during and after treatment ; (6) how to give the injections ; (7) reactions, local and systemic. The total number of persons who received anti-rabic treatment during the year was 4623, distributed between the following institutions : at the Pasteur Institute, Coonoor, 3375 ; at Government headquarter hospitals, 1248.

Parliamentary Intelligence.

HOUSE OF COMMONS.

TUESDAY, NOV. 13TH.

PARLIAMENT reassembled on Nov. 13th after the summer recess.

Panel Doctors' Fees.

Sir KINGSLEY WOOD asked the Minister of Health whether he could state the present position of the negotiations with the doctors on the panel lists concerning their duties and remuneration ; and whether he had conferred with the approved societies in relation to such matters.—Sir W. JOYNSON-HICKS said : I have now made two alternative offers to the doctors which will be considered by the Panel Conference to-morrow. As regards the second part of the question, for some months past a series of consultations have been taking place with the Approved Societies' Consultative Councils of England and Scotland, and, in addition, conferences have been held with representatives of the various important groups of approved societies in Great Britain in relation to both duties and remuneration.

Sir KINGSLEY WOOD : What is the additional sum involved in the offer that has been made to the medical profession, and from what source does the right hon. gentleman intend to obtain payment ?—Sir W. JOYNSON-HICKS : I am not prepared to make any statement until I get the reply of the doctors, which I hope will be to-morrow. If my hon. friend will put down a further question for Thursday I will be prepared to answer it.

Mr. SEXTON : May I ask the right hon. gentleman whether he anticipates that he will be able to make any agreement by the end of this week ?—Sir W. JOYNSON-HICKS : I hope to be in a position to make an agreement before the end of this week.

Major MACKENZIE WOOD : Would the right hon. gentleman consider the advisability of publishing an actuarial report on the new proposals ?—Sir W. JOYNSON-HICKS : If the offer I have made is accepted, I propose to lay a White Paper on the whole subject, which will include an actuarial report.

Sir W. R. ADKINS : Is it an agreement assented to by the approved societies ?—Sir W. JOYNSON-HICKS : No, Sir. I, as Minister of Health, after fully considering the whole matter, have made alternative proposals to the doctors. If either of these proposals is accepted legislation will be necessary, and I hope to have the responsibility of bringing in the legislation and submitting it to the House.

Dissolution of Parliament.

Mr. BALDWIN announced that Parliament would be dissolved on Friday, Nov. 16th.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Tuesday, Nov. 20th.

PATHOLOGY : at 8.30 P.M.
Communications :
Dr. E. E. Atkin : Cultural Characteristics of the Different Types of Meningococci.
Dr. O. Heath : The Meaning of Fever ; illustrated from Typhoid.
Baron Nopcsa : Evolution and Disease : based on Osteological Changes in Man and Fossil Animals.

Sheffield, Jessop Hospital for Women.—Sen. Res. O. £250. Also Two Asst. H.S.'s. Each £100.
Southport General Infirmary.—Hon. Aural Surgeon.
Training Ship "Exmouth" (off Grays, Essex).—Visiting M.O. £250.
Union of South Africa Govt.—Asst. P.'s. £460.
University of London.—University Readership. £500.
Western Ophthalmic Hospital, Marylebone-road, N.W.—Hon. Asst. S. 100 guineas.
West London Hospital, Hammersmith-road, W.—Hon. Asst. S. to Throat, Nose, and Ear Dept.
Willesden General Hospital, Harlesden-road, N.W.—H.S. £100.

Births, Marriages, and Deaths.

BIRTHS.

Heslop.—On Nov. 1st, at Stone Field, Kidbrook-grove, Blackheath, the wife of Major A. H. Heslop, D.S.O., O.B.E., F.R.C.S. Eng., R.A.M.C., of a daughter.

Higgins.—On November 6th, at 7, St. George's-terrace, Regent's Park, the wife of T. Twistington Higgins, M.B., F.R.C.S., of a daughter.

Morton.—On Nov. 6th, at Wellington-road, Bridlington, the wife of Dr. H. J. S. Morton, of a son.

Orme.—On Oct. 27th, the wife of Dr. Stuart Orme, of Chiltern Croft, Wendover, of a daughter.

Todd.—On Oct. 30th, at Lexham-gardens, W., the wife of H. C. Todd, F.R.C.S. Edin., of a daughter.

MARRIAGES.

Allan—Davies.—On Nov. 7th, at Liverpool, James Shewen Allan, L.R.C.S. Edin., to Muriel Davies, only child of Mr. and Mrs. Sydney J. Davies, of Bardwells, Roydon, Essex.

Bond—Skou.—On Nov. 6th, at St. Thomas's, Orchard-street, Major A. H. Bond, R.A.M.C., to Rasmine Skou.

Myles—Chidley.—On Oct. 27th, at St. Mark's Church, Surbiton, Captain Robert Boulton Myles, O.B.E., M.B., Ch.B., R.A.M.C., to Emilie Stanier, only child of Horace Chidley, Captain, British India Line (Indian Service), and of the late Mrs. Chidley.

Quinton—Murray.—On Oct. 31st, at Paddington, Percival G. Quinton, M.D., to Jessie, youngest daughter of the late J. D. Murray, Esq., of New Luce, Wigtownshire.

DEATHS.

Cripps.—On Nov. 8th, at Bentinck-street, London, William Harrison Cripps, F.R.C.S., of Glendaruel, Argyllshire, N.B., and Bentinck-street, London, aged 73.

Green.—On Nov. 5th, at "The Moorings," St. Albans, Thomas Henry Green, M.D., F.R.C.P., late of Wimpole-street, aged 81.

Woodrooffe.—On Nov. 9th, George Borries Woodrooffe, M.B., B.C. Camb., of Intake, Sheffield, aged 54.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE LIMITATIONS OF PHYSIOLOGICAL STANDARDISATION.*

By H. A. D. Jowett, D.Sc., Ph.C.

Ten years ago I had occasion to state that, despite the increase in our knowledge of the active principles of drugs, in many cases the use of galenical preparations continued concurrently with that of their active principles. For example, though an enormous amount of work had been done on the alkaloids of opium, the tincture, though standardised to a definite content of morphine, still held its own among prescribers, and the same might be said of tincture nux vomica and strychnine. On the other hand, it was true that in certain cases—e.g., pilocarpine and cocaine—the use of these active principles had almost superseded that of their corresponding galenical preparations. The opinion was expressed that whilst the ultimate goal—both logical and practical—must be the use of active principles, it was our deficiency of knowledge that prevented the attainment of this ideal. Whilst the patient work of pharmacists and chemists had rendered possible the control of galenical preparations of many drugs by chemical means, there still remained some which could not thus be standardised. Physiological methods of control, therefore—more or less quantitative—had been evolved and used for several potent remedies, when prompt action was required, principally ergot, the digitalis group, cannabis indica, and extract of pituitary body. Recently this control has been extended to synthetic products of the arsenobenzol series and to active principles in an impure condition such as insulin. A prolonged experience (of nearly 20 years) in the manufacture of the majority of these preparations requiring physiological control has so impressed me with the limitations of this method and with the difficulties involved in the attainment of a degree of accuracy to which the chemist is accustomed, that I wish to point out some of the difficulties met with by manufacturers in preparing substances to meet a physiological standard.

The Importance of Accurate Standardisation.

I would again emphasise the point that the use of galenical preparations, either chemically standardised or physiologically controlled, is only an intermediate step to the ultimate goal which must be the use of active principles whose purity can be determined by chemical methods. In my opinion, the aim which we have constantly to keep in view is this: to provide the medical man with the knowledge that he can prescribe such active principle or principles together with other substances either to modify their action, increase or retard absorption, &c., with the certainty that he obtains exactly what he prescribes. He will always have to deal with one variant—namely, his patient—and the determination of the variation will depend on his diagnostic skill. It is therefore important that the remedy he decides to employ will not vary, and this can only be accomplished by the use of pure substances. In this connexion I may quote the opinion of a most eminent authority on this subject, Dr. Dale, now in charge of the biological testing of the Medical Research Council. In 1913 in a discussion on the relation of the galenical preparations of ergot to the active constituents—ergamine, ergotoxine, and hydroxyphenylethylamine, he said: "As a medical man, he had no hesitation in saying the difficulty was really not so much on the pharmaceutical as on the medical side. . . . What they needed above all, to put the ergot question on a really satisfactory basis, was more clinical experience. If medical men wanted ergotoxine then ergotoxine could be obtained. On the other hand, if the amines of ergot were what medical men needed then, personally, he thought ergot had no place in the Pharmacopœia at all." These remarks still apply, and not only to ergot but to other drugs.

Before proceeding to my subject proper, may I briefly allude to the progress of standardisation. The difficulty has only existed, within recent years, with drugs of vegetable or animal origin, for the inorganic drugs such as sulphur, Epsom salts, calomel, &c., have always been capable of chemical control. The first method of using drugs was to employ the whole material, and even to-day many are exhibited largely in this form, such as opium, rhubarb, senna, and the various animal extracts such as thyroid gland, &c. The next step was to separate the active constituents from known inert material and thus came into use tinctures, infusions, extracts, &c. With the advent of these preparations arose the first attempts at control, such as determination of the extractive. Even to-day we have no knowledge of how to assay the value of the group of purgative drugs such as cascara, rhubarb, &c., and it is probably not necessary to attempt to value the activity—if such exists—of drugs such as dandelion. With the increase in our knowledge of the properties of alkaloids, methods of determining the total alkaloid content became available and one cannot overlook, in this connexion, the patient and classic work of the pharmacists, Farr and Wright. Further refinement took place in the determination of the active principles by isolating the alkaloid, such as morphine in opium, quinine in cinchona, or pilocarpine in jaborandi preparations, and, on the other hand, in the titration of the residue known as total alkaloid. There still remained a group of potent drugs for which no known chemical assay was available, and thus the methods of physiological control were welcomed. For 30 years they have been in use and have been improved by the work of numerous investigators and have now been officially recognised by the U.S.P. of 1916. Furthermore, the issue of certain remedies—viz., the arsenobenzol series and insulin—is only permitted after they have passed the biological tests of the Medical Research Council.

---

* Abstract of a lecture delivered at a meeting of the Pharmaceutical Society on Nov. 13th.

The Limitations of Physiological Control.

First let it be clearly understood what is meant by this term. It surely means the limit of experimental error of the method. Suppose samples of the same drug, chemically standardised or allowed a certain percentage of impurity, are submitted to analytical chemists in any part of the world, it will be found that their results will agree within a very small limit of error. For example, if a sample of opium properly taken and bulked is submitted to a number of analysts for determination of the morphine content, their results will be found to agree within ± 2 per cent. But no competent pharmacologist claims to test any biological preparations with this degree of accuracy; the error in most biological tests is about 20 per cent., in some tests greater, and in some cases it is difficult for the pharmacologist to say more than "high content," "medium," "poor," or "none."

The chief difficulties of physiological standardisation are (1) choice of method, (2) the standard, (3) variation in the animals used. The first two difficulties are well exemplified in the work of Burn and Dale on pituitary extracts. In dealing with the choice of method, they point out that if all the physiological actions or all those of therapeutic importance are due to a single active principle, any method capable of determining the relative concentration of that principle would be admissible, and that provided the action could be measured with accuracy it need have no relation to the therapeutic effect desired. But it should be pointed out that it is chiefly with these preparations where our ignorance as to the nature of the active principle or principles exists that physiological standardisation is necessary. If we had this knowledge we could adopt chemical standardisation and dispense with the physiological assay. Therefore, this difficulty of choice of method is inherent to physiological assay and is one of the causes of its limitations.

Having agreed, however, upon a method the next difficulty is having some standard against which to test the drug. For it must be noted that in most cases physiological standardisation has to be carried out by observing the effect produced by the unknown factor or drug against that obtained from a substance of known purity. In the case of pituitary extract the difficulty was to find a pure substance with which to compare the effect of the sample under examination. Burn and Dale tried histamine and potassium chloride but rejected both, and ultimately had to rely on an extract of pituitary gland prepared in a special manner. In this instance the standard adopted can be reproduced an indefinite number of times by competent workers and these successive "standards" when tested against—e.g., two ordinary good commercial pituitary extracts—would yield the same figure for relative potency on several occasions to within 20 per cent. of the true value of the sample or standard. Recent investigations indicate that it may be possible in the near-future for all laboratories to obtain and use samples of dried stable material taken from the same batch of standard.

There is finally the variation in the animals chosen, not only individually but generally, produced by differences in climate, season, location, and feeding. The only way in which to solve this difficulty is to take the average of a series of results obtained from a number of animals. This leads, however, to practical objections. How many animals are to be used? The greater the number the less the experimental error, but who is to fix the limit? With the larger animals such as rabbits, the expense involved adds to the difficulty. In drawing attention to these difficulties of physiological testing, it should be pointed out that in discussing this question with several physiologists it is found that all are fully aware of the limitations of their tests. They would welcome the replacement by chemical methods and this is also the case with regard to serums. Only a year or two ago it was impossible to differentiate between a horse serum containing a large amount of antitoxin from one with no antitoxic content, unless one were allowed to use animals. Recently, however, a flocculation test has been discovered and now, under certain conditions, it is found possible not only to identify the antitoxin serum by in vitro test, but to determine its value to within narrow limits. Should further experience confirm the value and accuracy of this flocculation method, it will be welcomed with a sigh of relief by all those whose business it is to make or test antitoxin.

A Plea for Further Research.

There is no doubt that, despite these limitations and the accident of experimental error, the biological control of potent remedies, such as ergot, the digitalis group, the arsenobenzol group, pituitary extract, and insulin, is most desirable. It has been pointed out that a more accurate method of testing is to be sought, as the losses caused by an error of testing in the case of such costly material as insulin may be considerable. There is no need to feel alarm about the efficiency of physiological standardisation, but what one does want to guard against is assuming a greater degree of accuracy for this method of control than is actually the case. The limitations of the method emphasise the importance of replacing it as soon as possible either by chemical methods, if satisfactory ones can be produced, or, better still, by the employment of the pure active principles.

May I, in conclusion, make a special plea that I shall not be misunderstood. As chemists we are accustomed to prepare and submit substances of a required degree of purity with the utmost confidence—knowing that we can substantiate all claims if necessary by experimental demonstration—but this is not the case when substances have to be submitted to physiological control. Its present necessity must be fully admitted, and full justice should be done to the patient and skilful work of the physiologists who carry out this work. The value of our ability to control these potent medicaments—even if such control is liable to a greater error than the chemist is accustomed to—certainly receives full appreciation from both prescribers and chemists. It is, however, most desirable that physiologists should aim at reducing their errors as much as possible, and that manufacturers should coöperate in making their preparations as reliable as knowledge permits. There is no doubt that this is being done, but it should not be the final aim. What I do plead for especially is further research into the composition of these drugs, with a view to the isolation of the active principles and for knowledge as to the effect of accompanying substances on their action. Above all, I wish to emphasise the importance of coöperation between investigators, manufacturers, and the medical men, so that these remedies can be exhibited in a condition most certain to bring about the effect desired on the patient.

PROBLEMS OF HEALTH SERVICE IN RURAL DISTRICTS.

In a lecture at the Royal Institute of Public Health on Nov. 7th Dr. W. A. Bullough set out the general lines of the scheme which has been adopted in the county of Essex with a view to preventing overlapping in the public health service. Dr. Bullough considered that a new mapping out of the sanitary areas and a replanning of the administrative units would be the best measure for dealing with an admittedly difficult problem, but since such changes were unlikely to be introduced in the next few years, it was necessary to meet the actual situation, and he believed that much could be achieved by coöperation between the existing bodies and by a combined medical service such as had been introduced, as an experiment, in Essex during the last four years. The aim had been to establish a combined service among the rural population and in urban districts of not more than about 20,000 inhabitants. In the county of Essex there were 47 sanitary authorities—5 boroughs, 25 urban districts, and 17 rural districts. Of these, 23 were served by part-time medical officers of health, 8 of whom were receiving a salary of £50 or less. While many part-time officers were doing excellent work, yet it was obvious that as a whole good work could not be expected where such salaries were paid, apart from the fact that their public duties might conflict with their private interests. Two or three medical officers of health had been appointed in Essex before the present scheme, under a section of the 1875 Act, but the great drawback was the size of the areas they were expected to serve, these being anything from 150,000 to 200,000 acres. The problems of time and distance had really driven Dr. Bullough to the idea of combination. Difficulties were sometimes experienced in getting different local health authorities to act together, but Dr. Bullough believed that where such unnecessary rivalry was found it was usually due to some lack of tact on the part of the officials.

In 1919 he had found one large combined area of 150,000 cres in the charge of a medical officer aged 85, who, though e had been a pioneer of public health work in earlier days, ras no longer active; there were, in addition, a county ouncil tuberculosis officer and a school medical officer, ut the three had never even met each other. In another istrict a tuberculosis nurse and a school nurse, who had been orking there for eight years, did not know each other. he large area referred to was split up into three, the com-ined medical officers of health being appointed for a trial eriod of one year. At the end of that time none had any ifficulty to record, and the scheme had gone on automatically ver since. The objection that claims of a dual authority f the county council and the local health authority would ash had not materialised. When there was an appoint-ent to be made the two bodies met, and the county council ould make a selection of several candidates, any one of hom might be appointed by the local health authority, us obviating any trouble on the score of the personal ctor.

What had really happened in Essex was that the county ad been split up into a series of smaller units than previously, ut instead of being worked by two, three, or four medical ficers, not always in harmony, the duties in the smaller eas were all carried out by one person. Dr. Bullough umerated as advantages: (1) Avoidance of overlapping and necessary travelling; (2) efficiency, economy, and an all-und sound investment; (3) the prestige of the medical ficer was raised, and the variety of duties added interest his work; (4) public health tuberculosis regulations and eatment of tuberculosis could be more efficiently carried t; (5) school duties could be usefully combined with work connexion with infectious diseases; (6) continuity of pervision and public health policy was maintained through-t the area; (7) confusion in the minds of parents, teachers, operty owners, and the like was avoided; (8) relations tween the various authorities were more harmonious;) the same policy applied to dental and nursing services.

CYNOGLOSSUM.

THE hound's-tongue, *Cynoglossum officinale*, is a common raginous plant in this country containing two alkaloids hich were shown by Dr. J. Gordon Sharp at the Thera-utical Society[1] in 1906 to bear some relationship to rare. Dr. Sharp found that cynoglossum renders the in moist and hyperæsthetic, stimulation of the sciatic rve or muscle only affecting the unpoisoned side, death curring with the heart in diastole. Probably on this count the drug once possessed some reputation against drophobia, and a pill containing hound's-tongue among her ingredients survived in official formularies until the ghteenth century. We have received through Messrs. ys, Muller and Co. (19A, Coleman-street, London, E.C.) paper by Dr. E. Poulopoulos, of Athens, describing inical experiments, first made 25 years ago in the surgical partment of the Hospital Evangelismos under Prof. alvani, in the use of cynoglossum powder as an application malignant ulcers of the skin. Dr. Poulopoulos's subse-ent experience leads him to believe that this action is t merely in the nature of a coincidence. The powder is read daily on the wound with sterilised vaseline and after o or three weeks the ulcer tends to cicatrise at the edge, e healing process extending gradually towards the centre. e begins by cauterising the hard edges of the ulcer and plying chromic acid to the base. Cases are quoted in ich the cure has persisted a number of years, but the thor does not set out the microscopical evidence on ich the ulcers were held to be of malignant nature.

TRANSMISSION OF "COLOUR-HEARING."

THE gift of "colour-hearing" is one which has sometimes barrassed its possessor who has kept this particular light der a bushel for fear his friends should mark him down a prospective inmate of an asylum. It seems, however, w to be generally agreed that the association of certain unds with certain colours is not a morbid state, though it undoubtedly rare. Psychologists have given the terms synæsthesias" or "secondary sensations" to these curious rrelations of the sense of colour with the senses of smell, ste, and sound. Goethe knew of this condition which, in 81, was the subject of important researches in Germany. was found by Bleuler and Lehmann that 12 per cent. of e 596 persons examined were in possession of synæsthesias. ese vary considerably in degree; a "colour-hearer" may perience a certain definite colour sensation when he merely inks of certain sounds and words without actually hearing em. This condition may become less noticeable with age, t throughout life certain sounds are associated with the me colours, a sound never giving rise to a sensation of een at one age and of red at another in the same person. ssessors of this gift are sometimes able to detect a discord only when they refer the matter to their colour sense. In a recent paper by Dr. H. Lundborg[1] an account has been given of a Swedish family in three generations of which this and other psychic phenomena were studied with a view to ascertaining whether or not they are inherited according to Mendel's laws. He has come to the conclusion that they follow these laws as faithfully as more material properties. In the first generation the father was a "colour-hearer." In the second generation there were three male and three female "colour-hearers," and in the third generation there was one male to two female "colour-hearers." In the same family such psychic qualities as a vivid imagination, a marked sense, or "bump" of locality, and a craving to travel or write were investigated, and it is interesting to note from the genealogical tables published by Dr. Lundborg that these qualities are handed down from one generation to another in a remarkably uniform manner.

COLONIAL HEALTH REPORTS.

Trinidad and Tobago.

Mr. T. A. V. Best, C.M.G., C.B.E., Colonial Secretary, in his report for the year 1922, states that the estimated population of the two islands is 374,650. The white population is chiefly composed of English, French, Spanish, and Portuguese, but the large majority of the inhabitants are natives of the West Indies of African descent, the balance being made up of East Indians, estimated at 121,249, and a small number of Chinese. The birth-rate was 31·82 and the death-rate 22·35 per 1000; the infantile mortality rate was 138·6 per 1000 births. The death-rates from the principal diseases were, per 1000: diarrhœa and enteritis, 1·78; malaria, 2·25; tuberculosis, 1·13; dysentery, 0·59; enteric fever, 0·54; and ankylostomiasis, 0·77. Influenza was prevalent generally, and was of mild type. There was no epidemic prevalence of any other disease. Venereal clinics on modern lines continue to be well attended at the out-patients' departments of the Colonial Hospitals in Port-of-Spain and San Fernando. On the recommendation of the Central Board of Health drainage schemes for the control of malaria are being carried out in the country districts. The intensive treatment of hookworm disease was continued by the Rockefeller International Board of Health, and the Central Board of Health coöperated by enforcing the establishment of latrines in advance of the treatment in the areas about to be operated in. The hospital accommodation provided comprises 340 beds at the Colonial Hospital, Port-of-Spain, 120 beds at the San Fernando Hospital, and 248 beds in the Government District Hospitals at Tobago, Arima, St. Joseph, Tacarigua, Couva, Prince's Town, and Cedro. There are small temporary hospitals at Sangre Grande, Mayara, and Toco. The climate of Trinidad—the most southerly of the West Indian islands—is tropical and may be divided into two seasons, a dry one from January to the middle of May, with an average rainfall of 2 to 3 in. a month, and a wet one from June to December, with an average of 8 in. per month. The coolest months are December to April. The average temperature during the day is 84° F. and during the night 74°. The conditions are healthy and by no means hurtful to Europeans, provided reasonable precautions are taken. Hurricanes are unknown.

Bermuda.

The official report for 1922 states that the population was estimated at 20,410—7001 white and 13,409 coloured. The birth-rate was 26·8 per 1000 among the white and 34·2 among the coloured population; the death-rate for the whites was 18·02 and for the coloured 19·2 per 1000. The infant mortality was 16·3 per cent. of living births, nearly one-half of the deaths occurring during the first month after birth. The number of stillbirths was equal to 4·4 per 100 living births. Illegitimate births numbered 12·6 per cent. of the total (3·4 for white and 16·8 for coloured population). The marriage rate was practically the same (8·40 per 1000) among both white and coloured. The average age at marriage was for bachelors 28, and for spinsters 22·5 years. The general health of the community in 1922 was good. Measles and influenza were prevalent during the winter, and whooping-cough was present throughout the year. There were 38 cases of typhoid fever, resulting in six deaths, which were in almost every instance directly traceable to defective sanitary arrangements. Typhoid infection through an infected water-supply is very rare, owing to the fact that every house is required by law to have an adequate rain-water cistern from which all supplies of drinking water are drawn. A leper asylum for the accommodation of eight lepers, hitherto not specially provided for, is being provided at Little Head, St. David's Island. In September certain members of the crew of the R.M.S.P. *Chignecto* were found to be suffering from a mild type of small-pox, and 41 passengers were placed under quarantine. Three of the contacts subsequently developed the disease, but no further cases materialised. Owing to the prevalence of this disease in epidemic form in certain of the islands of the West Indies it has been found necessary to take special precautions in the case of all passengers landing from the West Indies. The rate of infant mortality continued high, being at the rate of 165 to 1000 births; the chief causes were the inexperience and neglect of mothers and improper food. A lying-in hospital for the mothers of the poorer classes and some sort of parental clinic for the education of mothers are badly needed. The general sanitary condition of the island is deplorable when considered in relation to the high wages earned by the poorer classes and the generally high standard of living which prevails. No less than 170 residences were found unprovided with sanitary conveniences of any kind, while out of 4634 inspections made by the Health Department defects were reported in 50 per cent. of the dwellings. There is no adequate system of scavenging in operation, with the result that the fly nuisance is a serious one. In the summer months mosquitoes breed in great numbers among the unburied tins which accumulate in the more thickly populated areas, and also infest the large undrained marshes, particularly in the vicinity of Hamilton. It is proposed to obtain the services of Dr. Andrew Balfour, of the Wellcome Bureau, to advise on the whole situation. About 24,500 tourists are estimated to have visited the colony during the year, an increase of about 7500 over the figures for 1921. The St. George's Hotel had an exceptionally successful season. The floating of the Hotel Bermudian Company marks a further step on the part of private enterprise towards the development of Bermuda as a resort calculated to attract a type of visitor who wants a high standard of comfort and luxury, and is prepared to pay for it; at the same time the needs of the tourist have also been catered for by the opening of the Royal Prince Hotel. There is no regular direct passenger service to the United Kingdom, but during the summer of 1922 the Elder-Fyffes Company ran seven direct passenger boats each way, in which the accommodation was largely sought after.

[1] Acta Med. Scand., 1923, lix., 221.

Fiji.

In his report for 1922 the Hon. T. E. Fell, C.M.G., Colonial Secretary, remarks that although the year was one of trade depression the general health of the native did not appear to have suffered. The birth-rate for the period was 33·58 and the death-rate 23·23 per 1000. No serious epidemic of infectious diseases occurred. A few cases of typhoid were reported, and the number of dysentery cases was very small; this latter disease, once a serious menace to Fiji, is now almost negligible. Considerable progress has also been made in combating tertiary yaws and kindred diseases. Over 4500 injections of salvarsan were administered, and the incidence of the disease is now much less frequent than in former years, especially amongst children. A serious effort was made to deal with ankylostomiasis under the auspices of the Rockefeller Foundation, over 40,000 cases of all nationalities being treated. This disease is very prevalent and continuous effort will be necessary to eradicate it, as re-infection occurs rapidly. The Fijians and East Indians were found to be affected in almost equal proportions, but the species of worm generally found in Fijians (*Necator Americanus*) is different from that in Indians (*Ankylostoma duodenale*). It is interesting to note that although Indian immigration began over 40 years ago, the amount of mixed infection should be so small. The infection is comparatively slight in parts where the rainfall is low, but very heavy where it is high. Correspondingly, the physique and general well-being of the Indian population are much higher on the dry than on the wet side of the main islands. Intravenous injection of chaulmoogra oil continues to give good results in leprosy, and several more cases have qualified for discharges from the asylum. Education, through native medical practitioners and other means, is removing from the native mind the belief in the desirability of infection of children with yaws. The salvarsan group of drugs is much sought after, and, if funds should allow, it is now practicable to consider the eradication of a disease almost as deadly in its after-effects as syphilis is elsewhere. "Fiji," writes Mr. Fell, "is exceptionally healthy for a tropical country. It is protected against most of the infectious fevers by its distance from a continent. The absence of the anopheles mosquito prevents the occurrence of malaria. Plague, yellow fever, small-pox, or cholera have never gained admittance. Neither scarlet fever nor diphtheria appears able to flourish. First attacks of appendicitis hardly ever occur in Fiji. Dysentery is a steadily decreasing cause of ill-health. The climate is, however, generally unsatisfactory for those suffering from tuberculosis or asthma. The moist heat has an enervating effect on the nervous system. . . . There is evidence of the desire among some of the younger generation of Fijians for a more individualised mode of living. This generally finds expression in the men leaving their towns and working as labourers in the plantations. Impetus has been given to this movement by the substitutio of a considerable number of Fijians for Indian labourers i the sugar industry. Many of the men utilise the wag thus earned for communal purposes, such as in buildin iron-roofed houses in their towns and so obtaining reli from the constant work necessitated by repairs necessary t thatched native-built houses. A small number obtai exemption from communal duties and support themselv on their own plantations, whilst others earn their living a sailors, carpenters, boat-builders, and mill hands. Owin to their traditions of communal living very few Fijians ev attempt to engage in retail trade, and they remain conte to leave their trade in the hands of Europeans, Indians, an Chinese. Although many of them are employed in operati marine engines, the driving of motor-cars is left entirely the hands of Indians. On the other hand, the Fijians a taking very readily to the use of horses, and are evincing keen interest in horse-racing. In some districts footba and cricket are pursued with considerable keenness. Despi the increased tendency to become wage-earners, agricultu remains the main occupation of the Fijians. The cultivati of bananas, which was formerly largely in European hand is now almost entirely under their control. In the sug districts the natives are, in increasing numbers, employi more modern methods of cultivation, and are becomi accustomed to the use of European farm implements in th production of sugar-cane. A considerable number of the breed their own horses and bullocks, which they use f ploughing and general agricultural work."

A CRITICISED ADVERTISEMENT.

WE received, and duly published last week, an advertis ment stating the terms offered by the Nottinghamshi County Council to applicants for the post of County Medic Officer. We learn that those terms do not conform to t scale of salaries approved by the Representative Body the British Medical Association and the Society of Medi Officers of Health, but no warning reached us at the tin from either body, and none has been received since. But anonymous letter demands an explanation from us. Here it One communication was received Nov. 13th, dated Nov. 10 from Nottingham, with a reference to a local advertisem which had appeared previously. This letter asked us withhold publication from an issue of THE LANCET wh had been published three days before. The advertisem has been stopped, but we did not receive any assistan from the places whence it should have come.

TETANUS FOLLOWING OPERATION FOR APPENDICITIS.

AT an inquest before the deputy coroner of Preston Nov. 8th a verdict of "Death from misadventure" w returned on a woman, aged 38, who was operated on appendicitis in Mount-street Hospital, and died fro tetanus after appearing to progress favourably. Antitetan serum had been injected. The medical attendant suggest that the tetanus was set up by the catgut used in t operation. The coroner pointed out that every preca tion was taken to sterilise catgut, and that used in t hospital was obtained from the best firms, but in th case the bacillus or its spores might have resisted t sterilisation.

Bradshaw Lecture

ON

ROGNOSIS IN ANGINA PECTORIS.

Delivered before the Royal College of Physicians of London on Nov. 1st, 1923,

By JOHN HAY, D.L., M.D. MANCH.,
F.R.C.P. LOND.,
HONORARY PHYSICIAN, ROYAL INFIRMARY, LIVERPOOL.

PROGNOSIS is one of the more fascinating aspects of edicine. It is a balancing of the probabilities, and emands a wide experience, an intimate knowledge ıd a keen sense of proportion, combined with an stinctive capacity for weighing imponderables. amilial tendencies, the past history of the patient, e objective signs of actual disease, and those subtle ıt significant subjective discomforts pointing to preciation of function, must all be passed in review, ıd their relative importance weighed before venturing a verdict.

There are few conditions in which a clear statement to the future is more anxiously demanded than where in of an anginal nature has manifested itself, for e victim is conscious that in him "the unseen at of life and the target of death" is mortally tacked—there is with each paroxysm an ominous embling of the very foundations of a man's ing which leaves behind it a shaken and appre- nsive soul. The problem of assessing the expecta- on of life under these conditions is most difficult, ıd even after careful consideration of all the facts ıd an attempt to view the symptoms in their rrect perspective, an accurate opinion is not easily tained. The prognosis given may be entirely stifiable and yet prove far from the truth, for there e always factors beyond assessment. Where so uch is uncertain we must seek for any solid ground which to base our opinion.

I have recently reviewed the records of 309 patients whom the dominant feature was pain of an anginal pe, in an attempt to formulate the results of my rsonal experience; and I have dealt with them ore particularly in relation to prognosis. It is this pect of the problem which I thought might usefully rve as a subject for our consideration. It is not my tention to enter the debatable ground either of the sential nature of angina or of the special pathological anges which are said by some to be causally evitable. We are now dealing, not so much with e interpretation of the pain in angina, as with the ortality. It is sufficient to point out that two of e greatest living authorities, both distinguished ysicians, and men who have devoted many years their lives to this very subject, have arrived at ametrically opposite conclusions.

I refer, of course, to Sir Clifford Allbutt and to James Mackenzie. The latter holds that in angina e symptoms are produced by exhaustion of the heart ıscle and he stresses the importance of coronary d myocardial disease. He concludes that angina a symptom-complex rather than a disease. Sir fford Allbutt states with no uncertain voice that gina *is* in truth a disease, and that the symptoms due, in say 90 per cent. of the cases, "to disease the thoracic aorta and especially of its outer vestment," and further, "that the coronary eries and the myocardium have nothing to do th the pain of angina." In fact, with good-natured sapproval, he terms this view "a stiffnecked sumption."

CAUSATIVE FACTORS OF ANGINAL PAIN.

Whichever of these two views we are disposed to cept as the more correct, it will be generally con- led that anginal pain is the resultant of two factors: Afferent stimuli passing from the heart and aorta; d (2) the sensitiveness of the receiving apparatus; in other words, of those levels of the central nervous system associated with the heart and aorta. It is to Sir James Mackenzie that we are more particularly indebted for the full appreciation of the importance of this latter factor.

From the interaction of these two we have pain, and the accuracy of prognosis will depend on a careful consideration of both, and a decision as to which of the two is dominant. The more exalted the sensitiveness of the segments involved the more susceptible to stimulation, then the less ominous the outlook and the greater the ground for hope of a satisfactory response to treatment. On the other hand, the second essential matter for investigation is the reserve power of the heart, the health of the aorta, arteries, and myocardium, and also the permanent load on the heart or the work that it is called upon to perform, independently of any physical effort.

My series includes both private and hospital patients, and, in accordance with the usual experience, the large majority were private. There were 309 patients in the series up to the end of July, 1923.

TABLE I.

309 Cases of Angina.—Males, 243; females, 66 (proportion 3·7 : 1).

V.D.H.—35 cases: males, 30; females, 5. Aortic valves diseased in 34, mitral stenosis uncomplicated in 1.

Systolic Blood Pressure.—(35 V.D.H. patients not included.)

—	mm. Hg.			
	Under 150.	150 179.	180 199.	200 and over.
Males, 206	73	62	28	43
Females, 59	10	12	10	27

Systolic Blood Pressure 180 mm. Hg and over:—

Males ..	71 in 206 =	34·5 per cent.
Females ..	37 in 59 =	62·7 ,,
Total ..	108 in 265 =	40·7 ,,

Table I. gives information concerning the type of patient, the height of the systolic blood pressure, and the incidence of valvular disease. There were 35, or 11·3 per cent., in whom I had made a diagnosis of valvular disease of the heart. On analysis of these it was found that, with one exception, the aortic valves were damaged. There was definite aortic regurgitation in 26, and some degree of aortic obstruction in ten patients. In the whole group of 35, only one patient suffered from frank uncomplicated mitral stenosis.

Two among many points of interest particularly attract our attention: (1) The relation of the electrocardiographic (E.C.G.) findings to prognosis; (2) the diagnosis and prognosis of minor angina.

Before considering them, a general but cursory survey of the problem may be permitted, and it would be well to state at once what the term "angina" signifies.

SIGNIFICATION OF THE TERM "ANGINA."

By angina pectoris I have in mind an arresting form of cardiac pain, substernal rather than submammary, in which the patient is conscious of a sense of oppression, or constriction, which may reach a high grade of intensity, even a condition of intolerable anguish. This pain has certain well-recognised lines of radiation and is often induced by effort or emotion. There are, in addition, characteristic associated symptoms not invariably present, notably the sense of impending death, and indescribable anguish of mind accompanied by varying vaso-motor disorders such as cold sweats and deathly pallor.

It is well to remember that the information desired by the patient and his friends refers more often to the duration of life than to the mode of death, although the latter is not infrequently the subject of their inquiries.

Causes of Death in Anginous Patients.

The first important factor when considering the mortality is to recognise clearly that an anginous patient does not necessarily die in an anginal seizure, but frequently from other and less dramatic causes. A number pass away quietly in their sleep without apparent distress, or death may be sudden and painless apart from sleep. In these cases the final event is probably that of fibrillation of the ventricle, and is without any direct relationship to an anginal attack. A large group is that formed by those who die the slow death of progressive cardiac failure. Then there are those who succumb to cerebral hæmorrhage, while a few die from uræmia with its protean manifestations; and, as one would expect in a malady which may persist for years, many die from causes remote from the angina and its associated pathological conditions.

I have been able to obtain information concerning the mode of death in 65 patients.

Of these, 32·3 per cent. died in or immediately after an anginal attack; and 24·6 per cent. died either in their sleep or suddenly—a total of 37 in 65. Twelve died from cardiac failure, and 16 from a variety of causes, some quite independent of the anginal condition. These are given in Table II.

Table II.

Anginal attack	21	Died in sleep	4
Sudden death	12	Cardiac failure	12
Other causes	16		

(Diseases of kidneys, 3; diabetes, 1; cerebral hæmorrhage, 2; pneumonia, 1; gangrene of legs, 1; gangrene of lungs, 1; influenza and bronchitis, 1; suicide, 1; sarcoma, 2; senility, 1; pernicious anæmia, 2.)

If we accept the view that sudden death in these patients is usually due to fibrillation of the ventricle, and the evidence, clinical and experimental, favours this supposition, it is of interest to consider the factors predisposing to this lethal tumult of the myocardium. This has a definite bearing on prognosis.

Prof. J. A. MacWilliam pointed out in August last[1] that the exciting cause of fibrillation is "an increased demand on the powers of the heart and more or less stress on the organ"—for example, muscular effort or emotional excitement. Fortunately such factors leave the normal heart unaffected and are capable of inducing fibrillation only when the heart is in an abnormal condition of excessive susceptibility. Certain drugs, such as digitalis, increase the liability to fibrillation and there are probably other drugs and abnormal conditions with a similar tendency, but a "prominent part in the setting up of abnormal susceptibility to fibrillation must be assigned to defective coronary blood-supply." The condition of the coronary arteries is, therefore, one important factor to be considered when estimating the liability to sudden death.

The liability to death *during* an anginal seizure in any particular case is almost incalculable, and I frankly admit that I know of no certain rule by which one can decide the probability of a sudden, dramatic, and painful exitus. An increase in the frequency and severity of the attacks is obviously ominous, but even when this increases manifest uncertainty is still present. An anginal seizure may come like a bolt from the blue. The first attack may be the last, with possibly no premonitory sign or signs to indicate that death is on the threshold.

It is well recognised that the severity and gravity of the initial seizure give no indication of the liability to an early recurrence, though in the presence of the attack itself, confronted by the physical and mental distress, it is difficult and almost impossible to take this dispassionate view. Again, it is equally if not more important to appreciate the significance of some of the minor but ominous substernal sensations, often so lightly dismissed. If, however, the patient survives the first stormy onset, years may pass before there is any recurrence of a comparable severity.

Expectation of Life in Anginous Patients.

While recognising the elusive and incalculable element of uncertainty, and frankly admitting the possibility of a sudden and terminal anginal seizure, I believe that the expectation of life in these patients can be predicted with some degree of justifiable confidence. The outlook depends on the integrity of the myocardium, and the health of the general arterial tree. It will depend also on the degree of coöperation given by the patient, who must be honest with himself and prepared to live down to the level of his damaged organs. Death is often the outcome of the associated conditions, and the cry of the heart is nothing more than the signal that it also is involved in the general depreciation. Whatever indicates a tendency to cardiac failure is of significance, and search must be made for every evidence of myocardial disease or functional impairment. It is significant that the first symptom of angina can often be related to some sharp illness, involving a pyrexia of possibly only a few days' duration. Such a history, if recent, indicates caution in offering an opinion as to the prognosis, until sufficient time has been allowed for the myocardium to recover.

Dyspnœa.

One indication of an impaired myocardium is, of course, dyspnœa. This symptom, though frequently present in patients who suffer from angina, is not a characteristic feature of an anginal seizure. It is not an element in the diagnosis, but it is a valuable aid in prognosis, as an indication of myocardial inadequacy. When dyspnœa is induced easily in an anginal patient who presents a normal blood pressure, with no demonstrable enlargement of the heart and no valvular disease, one is justified in suspecting a defective blood-supply to the myocardium, unless there is some definite history suggesting a temporary toxæmia of the heart muscle. In these cases the prognosis would be grave, and still more grave if the liability to the dyspnœa and pain, or both, is more and more easily induced in spite of a carefully regulated life.

Pulsus Alternans.

As another sign of value I would mention the pulsus alternans, the ominous significance of which is not sufficiently appreciated. I think this is partly due to the fact that this variety of pulse is not readily recognised and is apt to be confounded with other and innocuous forms of arrhythmia. It is characterised by an alternate lessening of the amplitude of the arterial pulse, the pulse remaining regular in time, and it is most easily perceived when recording the blood pressure. As the pressure in the embracing armlet rises the smaller and alternate pulse is obliterated, and the pulse-rate at the wrist is suddenly halved. A polygraph record enables the transient appearance of this irregularity to be noted, when it occurs for a few seconds after the appearance of an extra-systole, or after exercise. When appearing in patients who suffer from anginal attacks, it is a sign of undoubted significance, and it in itself would justify a very grave prognosis.

However, pulsus alternans is rarely the only untoward manifestation, being usually accompanied by other indications of cardiac distress—such as an increasing breathlessness, attacks of nocturnal dyspnœa, or even of periodic breathing. As with dyspnœa, it is not a symptom or indication of angina, but it does give a clear lead as to prognosis in any anginal patient. In them it is a manifestation of distress, and probably has for a pathological basis fibrosis of the myocardium. Dr. Davenport Windle[2] goes so far as to say that "in any patient with arterial disease and alternating pulse, anginal attacks have occurred or will occur sooner or later, unless dropsy sets in, when, if present, they will cease." In his series of 17 cases no patient lived longer than 17 months after the presence of pulsus alternans.

My experience is that it is not a common sign, but this is perhaps due to the fact that I have not had the pportunity of watching the patients day by day, d of observing them after exercise, and on those casions when premature beats were in evidence, for der such conditions a latent alternation becomes ankly evident. I have, however, noted alternation 12 anginal patients. Of these, ten are dead, and e average duration of life in this 10 was 9 months, o living 25 months after the alternation was served. An anginal patient who presents well-arked alternation is not likely to live beyond 12 to 18 onths.

Raised Blood Pressure.

On analysing the records it is clear that one of e commonest abnormal conditions associated with gina pectoris is a raised blood pressure. In 300 tients, after exclusion of the 35 suffering from lvular disease of the heart, and 9 in whom there as no record of the blood pressure, 108 (40 per cent.) d a systolic blood pressure of 180 mm. Hg and er. These 108 comprised 71 males (out of 206, at is, 34·5 per cent.) and 37 females (out of 59, 62·7 per cent.). It is noteworthy that among the omen the percentage of cases with a high blood essure is much greater than among the men.

Certain of these patients will be suffering from ronic interstitial nephritis, and in them the ognosis will be influenced by the result of tests dertaken to determine the renal efficiency, and by e appearances present in the retina and optic discs.

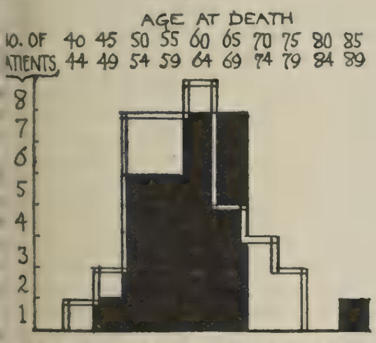
The significance of hypertension, apart from the ssibility of associated kidney disease, lies in the ct that a raised blood pressure adds to the load hich the heart carries, and in addition is generally sociated with a diffuse arterio-sclerosis; so that is type of patient is predisposed to cardiac distress d cerebral accidents. Even so, the careful figures of ackenzie[3] indicate that the expectation of life in ginal patients is not materially modified by an sociated high blood pressure. This is an unexpected ding. In his series the mortality curve of those tients with a systolic blood pressure of 180 mm. Hg d over, followed very closely that of the mortality rve of the whole series, though, if anything, death curred a little earlier in his high blood pressure cases.

The impression I have formed is, that if it be found ssible to modify even slightly an excessive blood essure, the symptoms of the patient are ameliorated, t I do not find that the expectation of life has been preciably increased.

Age at Death of Anginous Patients.

I have records of the age at death and the duration of ginal symptoms in 60 patients. In 26 the systolic blood pressure was 180 mm. Hg or over—in them the average age at death was 60·8 years, and with only two exceptions death occurred between the ages of 50 and 70. In the other 34 patients the systolic blood pressure was below 180 mm. Hg, and the average age at death—59·5 years—varied only slightly om the high pressure group. I was surprised to find at the average duration of life from the first pearance of anginal pain was, in fact, shorter in e low pressure group. It was 3½ years as compared with 4½ years in the high pressure group. Fig. 1 shows graphically the age at death in the two groups.

FIG. 1.

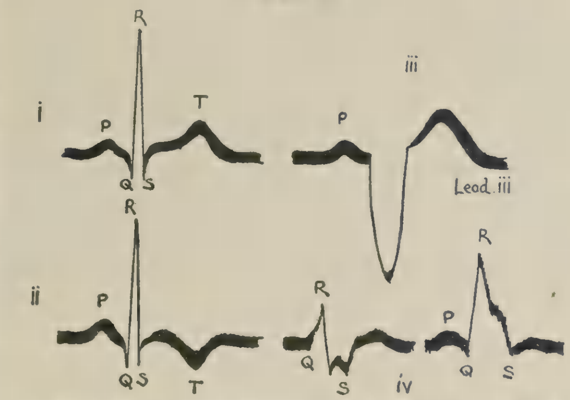


e of death in 60 patients. The 26 black squares represent patients with a systolic blood pressure of 180 mm. Hg or over. The 34 squares surrounded by double lines represent patients with a systolic blood pressure below 180 mm. Hg.

THE ELECTROCARDIOGRAPH IN PROGNOSIS.

Within recent years the functioning power and integrity of the myocardium have been investigated by means of the string galvanometer, and attempts have been made to correlate changes in the shape of the E.C.G. with prognosis. The fullest reports dealing with this have been from the Mayo Clinic at Rochester, by F. A. Willius,[4] who has kept careful records since 1914, the after-history of every patient being watched. J. E. McIlwaine and J. B. Boyd Campbell[5] have recently published interesting figures bearing on this subject; while B. S. Oppenheimer and N. A. Rothschild, in 1917,[6] reported 62 cases in which the Q-R-S complex in the E.C.G. was abnormal; 27 of these cases were patients suffering from angina. The average age of the 62 patients was 54. Within two years 50 per cent. were dead. They compare this death-rate with that of 22 other anginas in whom the E.C.G. were normal. The average age of this second group was 52. During a similar period only one in this group is known to have died; 17 of the 22 were known to be alive at the date of publication—16 fairly well and one in a precarious state. Figures such as these and those to be mentioned are arresting.

FIG. 2.



i. The normal electrocardiogram; P is due to systole of the auricles, Q, R, S, and T to systole of the ventricles. ii. Inversion of the T deflection, or T wave negativity. iii. The diphasic complex resulting from a lesion in the right branch of the bundle; the curve is reversed in a lesion of the left branch. iv. Two examples of "spread" of the Q-R-S complex; compare these with the normal Q, R, S in (i.) and (ii.). Inversion of T is only of significance in the absence of digitalis medication.

Hitherto the E.C.G. has been chiefly of value in analysing the various forms of arrhythmia. There are reasons for believing that in it we may find valuable assistance in prognosis. An E.C.G. represents graphically the variations in electric potential associated with each contraction of the heart. A normal systole is a coördinated contraction of the myocardium in response to a stimulus reaching it along well-recognised channels. Under normal conditions the stimulus does not reach the whole myocardium simultaneously, but in an ordered sequence. It flows along the conducting channels and reaches the various areas of the myocardium at such times and in such a manner that the resultant systole of the whole heart is an efficient coördinated movement. Any break in the functional continuity of the conducting channels causes a deviation from this orderly sequence. These deviations are revealed in the E.C.G.

An abnormal E.C.G., therefore, indicates that the fibres or groups of fibres composing the heart muscle did not contract in their proper relation one to the other. The commonest cause for this is some organic change in the myocardium, damaging or destroying the junctional tissues, the auriculo-ventricular (*a.-v.*) bundle, and Purkinje system: but functional block due to some temporary cause may be solely responsible. An outstanding example of this change in the E.C.G. curve is met with when disease obliterates one branch of the *a.-v.* bundle. There is then a complete alteration in the ventricular complex. There are also numerous other less dramatic deviations which have a definite significance. These are shown in Fig. 2. It is suggested that such abnormalities in the E.C.G. can be utilised in arriving at a prognosis.

---

[3] Angina Pectoris, pp. 115–116.

[4] Archives of Internal Medicine, vol. xxx., No. 4, p. 434.

[5] Brit. Med. Jour., Sept. 15th, 1923.

[6] Journal of American Med. Association, 1917.

Willius started with the assumption that there *is* a relationship between an abnormal E.C.G. and the expectation of life, and he arranged those patients yielding an abnormal E.C.G. into three groups: (1) With significant T wave negativity, an inverted T; (2) with aberration or spreading of the Q-R-S complex in all derivations; and (3) with coexistence of these abnormalities, E.C.G. combining (1) and (2). Under each of these headings patients were arranged in clinical groups, and a careful series of controls collected comparable in age, sex, clinical type, and degree of decompensation. The total number of patients observed was 696, over a period of 5½ years. I have abstracted his figures dealing with angina, and they are as given in Table III.

TABLE III.—*Cases of Angina* (*Willius*).

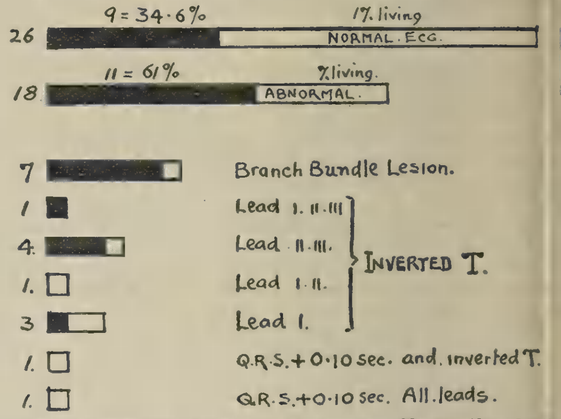
—	Total.	Heard from.	Dead.	Mortality per cent.	Controls.			
					Total.	Heard from.	Dead.	Mortality per cent.
A.—Inverted T:— Leads 1; 1 & 2; 2 & 3; 1, 2, & 3	58	47	27	60·0	58	43	11	25·5
B.—Q, R, S + 0·10 sec.:— All leads	10	9	6	66·6	10	6	2	33·3
Combination A + B ..	13	11	10	90·9	13	11	3	27·2
Grand total ..	81	65	43	66·0	81	60	16	27·0

We see, therefore, that Willius dealt with 81 cases of angina manifesting certain definite abnormalities, and with 81 controls—patients comparable in every way except that their E.C.G.'s were normal. He obtained full information concerning 65 patients, and of these, 43 died—giving a mortality of 66 per cent. In the 81 controls full information was obtained in 60, of whom 16 were dead—a mortality of 27 per cent. Willius has no hesitation in stating that the higher mortality is the result of vascular degeneration of the obliterative type, and he considers that the abnormalities in the E.C.G. are directly caused by these degenerative processes.

We cannot take this view as proven, though I believe we may fairly say that, other things being equal, an abnormal E.C.G. indicates the probability of degenerative changes in the myocardium, and in consequence a diminished expectation of life.

My personal experience is limited. I have taken E.C.G. records in 60 cases of angina, but as 16 of these have come under observation during the last six months they are not included, thus leaving 44 to be considered. Of these the E.C.G. was normal in 26. Nine are dead (one dying from pernicious anæmia), giving a mortality of 34·6 per cent. Of the 18 showing definite indications of abnormal conduction, 11 are known to be dead—a mortality of 61 per cent. The details are given in Fig. 3. In seven there was clear evidence of branch bundle block—six are dead. The duration of life after the onset of anginal symptoms was relatively short in each of the six. Dr. McIlwaine[5] has reported 15 patients with a branch bundle block, all of whom died in the course of 12 months—a mortality of 100 per cent. Of the 44 anginal patients there were 18 in whom it has been possible to determine the duration of the anginal symptoms from their onset up to death. In 11 with a normal E.C.G. the average duration of life from the onset of angina symptoms to death was $4\frac{6}{11}$ years; whereas in the smaller group of seven abnormal E.C.G. the expectation of life was only $2\frac{4}{7}$ years. These figures, though small, definitely corroborate the results obtained by Willius, McIlwaine, and others.

FIG. 3.



Electrocardiographic detail in 44 cases. Shows the death occurring in the 44 patients referred to in the text. The figures to the left indicate the number of patients represented by the corresponding column. The black spaces indicate the dead.

To me they are convincing, and bring us back t our original standpoint. We can find sure ground on which to base our prognosis in the integrity of the heart and arteries. The mortality in angina pectori varies with the health of the myocardium.

ANGINA MINOR.

Than Sir Clifford Allbutt[7] no writer has laid greate emphasis on the importance of confining the term "angina" to a group of cases in which there is, a the pathological basis, a lesion of the presigmoid area of the aorta; nor one who looks more suspiciously a any diagnosis which does not conform strictly to type Yet even Sir Clifford Allbutt admits and emphasises the gravity of minor angina, and no one has more aptly coined phrases to convey the sinister significance of certain slight and transient symptoms. If I interpret Sir William Osler[8] correctly he considered the term angina minor as applicable to the neurotic, toxic and vaso-motor groups, and excluded those patient presenting signs of cardio-vascular disease. I hardly think this a satisfactory use of the term. Angina minor indicates rather a transient or mild attack o anginal pain, but of so moderate and mitigated a severity that there is a risk of it being passed over a of little moment. Such cases I desire to emphasise for they are neither uncommon nor without importance. In them the prognosis is often gravely a fault, in most instances because of an incorrect o an inadequate diagnosis. The symptoms are no recognised as anginal, and their ominous significance is overlooked. The cardiac origin of the symptoms even when suspected, is too often dismissed and some other explanation is offered, because on examination no evidence may be forthcoming of cardio-vascula disease. The diagnosis must therefore be made in many of these patients on the subjective manifestations alone. These minor distresses may occur a premonitory warnings and are as essentially angina as the obvious major seizure, for as Sir Clifford Allbutt says, "The first muffled aortic groan is bu the prelude to the fiercer pang of stark angina." On the other hand, the major and minor may alternate or the minor may come as an aftermath or echo of a previous major attack. Such are of a particula nterest to every clinician, because the nature of the nalady has then been openly declared.

---

[7] Disease of the Arteries, including Angina Pectoris, vol. ii.

[8] The Lumleian Lectures on Angina Pectoris, THE LANCET 1910, i., 697.

An accurate prognosis depends upon the recogition of the significance of these minor anginas. t is remarkable how frequently one elicits a history f slight substernal pain or other discomfort, someimes in peculiar and unusual sites, which arises as he result of effort, exposure, or excitement in patients vho finally present the typical clinical picture of rave angina.

It is not surprising that these early manifestations re often misinterpreted. For example :—

The first indication of angina in a man of 60 was a pain tuated just below the level of the thyroid on each side of he trachea, gripping in character and induced by exertion; a few months this was accompanied by substernal pain f a moderate intensity. Six months from the onset he was uddenly seized by paroxysms of anginal pain, lasting with arying intensity for 12 hours, during which his life was espaired of.

As a typical example of a minor angina the following ill serve :—

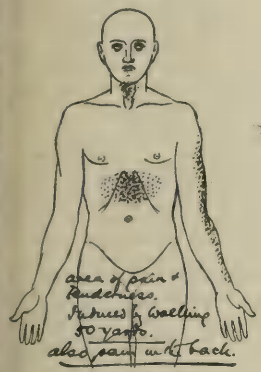
A man of 64 complained of a gripping pain of moderate tensity and a sensation of pressure, unaccompanied by ny dyspnœa. The pain was substernal, at the level of the ird space, and covered an area the size of a crown. It as induced by walking and ceased at once when he stood ill. If he persisted pain and numbness appeared in the ft forearm and hand. He first suffered in this way for vo years and had been under continuous treatment for indigestion."

In another patient, a man of 56, the first indication of ouble dates back to December, 1920, and consisted in pain ross the chest at the level of the nipples brought on by alking up a slight incline. If he stood still it subsided. It ased to trouble him, but recurred in March, 1921, when a agnosis was made of "indigestion" but, as the doctor id, "with mental reservations." A fortnight later he had e attacks of severe angina arising in the same area, and companied by pain extending from the tip of each shoulder wn the arms to the thumbs. He thought he was dying ring the acme of the attack, and was left emotional and pressed.

It would be easy to relate many similar instances here the slight and transient symptoms were llowed by the overwhelming distress of unquestioned gina. Probably the most common error is that of belling the discomfort of minor angina "indigestion," in the cases just related; and this diagnosis is ten accepted until the patient is in the grip of a ajor attack when, too late, the import of the previous indigestion" is obvious.

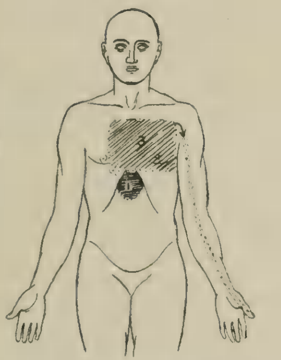
The only safe course is to view with suspicion eryone over middle age whose "indigestion" is duced by effort or exposure to cold, and which fades vay on the cessation of stress or when the patient ts comfortably warm. Such a history calls for reful examination of the whole cardio-vascular stem. This discomfort is usually substernal, a nse of tightness over the lower third of the sternum, metimes confined to the area of the xiphisternum, ore rarely definitely localised in the epigastrium, the pit of the stomach."

FIG. 4.



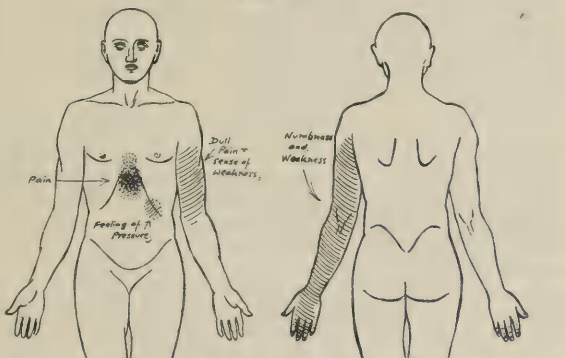
Male aged 64.

FIG. 5.



Male aged 52. Area of pain (2) not shown, being on the back.

FIG. 6.



Front and back view of male, aged 56, with minor angina and no severe pain, who died in a first attack of major angina.

This feeling of weight or oppression may be transient or of some duration. It may be the precursor of a devastating seizure or jog the memory of the patient and remind him of a former and terrible experience. The peculiar feeling of imprisoned flatus lodged behind the lower third of the sternum, or the sensation of food having "stuck on the way down" are suggestive. It is often true that with these substernal sensations there is an element of uneasy apprehension. I have seen 16 patients in whom the pain was definitely confined to the epigastrium, or took the epigastrium as its starting-point—spreading upwards behind the sternum if the patient persisted in the effort which induced the pain.

It is no adequate explanation to pass this pain off as being in every case nothing more than hepatic or other colic, though I admit that such an error in diagnosis does occur, and this possibility must be carefully considered. In one most typical case of epigastric angina, in which an autopsy was made, the stomach, duodenum, and gall-bladder were found free from any disease. It should be remembered that even when pain in the epigastrium is the dominant feature of the anginal attack, there are often additional symptoms, such as cramp-like and other sensations in areas indicating the cardiac origin of the epigastric pain, which in doubtful cases would help to clinch the diagnosis.

The associated phenomena may only appear when the effort inducing pain is continued in spite of the warning initial distress, and as the patient improves under treatment physical effort may fail to do more than provoke the primary epigastric ache.

A few examples may be quoted :—

A male, aged 64 (Fig. 4), with a systolic blood pressure of 200 mm. Hg and diastolic 100 mm. Hg, who experienced a dull aching pain in the epigastrium whenever he walked 50 or more yards, followed by pain between the shoulder blades, principally to the left of the spine. Simultaneously he felt an aching and numbness down the outer side of the left arm with occasionally an aching in the neck on each side of the larynx and trachea.

A male, aged 52 (Fig. 5), in whom walking brought on severe pain in the epigastrium at (1) on the figure. He experienced a sensation of being constricted in that area. This pain passed through to the back about the level of the angle of the scapula and was felt there as a broad horizontal band. It then spread over the front of the chest—the area indicated by (3)—and a cramping pain passed down the left arm in a narrow strip to the thumb. An attack lasted 3–15 minutes, and caused him to break out into a cold sweat. Under treatment the attacks became much less frequent and markedly less severe with great diminution in the area involved. The pain became focused in the epigastrium. The acute pain in the chest and the cramp-like feeling down the arm were no longer induced by effort. He died 16 months after coming under observation.

The description given by patients of their epigastric sensations varies considerably. It has been described as a "pain and tightness, with a gripping sensation," which disappears on "easing off." "An awful pain, induced by hurry, worry, or excitement." Another man whose pain was in the xiphisternal area and an inch or two below: "Pain, tight and very severe, attended by apprehension, with numbness in the arms and once or twice accompanied by vomiting." Another said: "An acute feeling of indigestion becoming something damnable."

The following case combined several features of interest in prognosis.

A male, aged 56 (Fig. 6), complained of pain in the pit of the stomach when he walked. This pain, which was not severe, passed up a few inches behind the lower third of the sternum and simultaneously he experienced a sensation of numbness and weakness in the left arm. During an attack he was conscious of a difficulty in breathing, but there was no increased frequency in respiratory movements. He was a big hefty man weighing over 15 stone. The blood pressure was within normal limits, and there was no evidence of valvular disease, though the heart was moderately enlarged. Deep cardiac dullness 5 inches to the left of mid-line, and the peripheral vessels definitely sclerosed. His symptoms dated from an attack of influenza some nine months previously. The pain was never agonising, nor was there any fear of impending death. He had noticed that the attacks became more and more easily induced. The E.C.G. showed the typical diphasic complex of branch bundle lesion. Here was a man who had never had any severe or devastating pain, and in whom the chief site and area first to be attacked was the epigastrium. The pathological lesion was progressing and there was an ominous abnormality in the E.C.G. He had a month in bed with apparent benefit. The attacks became fewer in number and less easily induced. However, seven weeks from the date of his first visit he died in a severe attack of major angina, which lasted an hour, and which came on while he was lying placidly in bed.

ERRATIC OR ECCENTRIC ANGINAS.

The erratic or eccentric anginas may take some peculiar forms. In each, however, the symptoms are associated with effort and tend to diminish on cessation of the exciting cause. Sometimes the first and possibly the only discomfort is felt in the face, neck, or wrist.

A woman of 52, with systolic blood pressure of 190 mm. Hg, had as a first indication a feeling of tightness in cheeks and mouth as if acutely engorged. This extended from under the eyes down to the jaws. These sensations might be the only responses to effort, but if she persisted, then followed a choking sensation in the jaws and lower neck, culminating in typical constriction around the chest, and finally a fully developed major angina.

In other patients a fullness and sensation of bursting in the eyeballs is the first response to physical strain. The pain may begin in the back between the shoulders, and, as in a man of 57, pass across the axilla round to the right nipple area, and extend down the right arm as far as the elbow. This man, after many attacks similar to the above, died in a severe seizure seven months after coming under observation.

When the pain appears to evade the sternal area and is focused in one or other shoulder and upper arm, possibly in the elbow or wrist, it is not uncommon to find that the patient has been under treatment for neuritis or muscular rheumatism. Careful cross-examination usually elicits a straightforward statement that these scattered pains bear a definite relationship to physical effort, and sometimes a history of one or more attacks of frank angina can be obtained.

As further examples of what one might call minor angina I will refer to two cases, in both of which the symptoms complained of were slight, but death ensued during a full-blown attack.

A man of 40 complained of a feeling of pressure and weight over his heart which he described as tension, and with this there was a sensation of weight in the left wrist which caused the arm to feel useless. These indications were first noticed in February, 1921. I saw him in November of the same year. Excitement or effort induced the symptoms. There was also a history of two syncopal attacks. He was a most irritable and highly-strung man, apparently organically sound. Three or four years ago he had to cease work owing to a nervous breakdown. His blood pressure was normal. The heart was not enlarged and the heart sounds were normal with the exception of slight accentuation of the aortic second. He had just returned from a long business trip in Europe and was alert, aggressive, and most irritable I admit I was unduly impressed by his nervous temperament, and consequently did not take a sufficiently grav view of the outlook. Within seven days he was seized b the first and only attack of typical major angina, and died.

The second patient was a man of 75, who for the las eight years had suffered from attacks characterised by feeling of tightness behind the sternum and a sensation o discomfort, sometimes becoming *almost* a pain, whic tended to spread to the left shoulder and down to th elbow. Walking up a hill or against a wind would induc this discomfort. Latterly the pain had been more easil excited, and on one or two occasions within the last si months had occurred while the patient was in bed—alway an ominous sign. When the pain was present his breathin was quite easy, and there was no element of apprehensio Physical examination gave a blood pressure of 160 mm. H systolic, and 80 mm. Hg diastolic, the size of the heart wa within normal limits, and there was no variation in th sounds; rate of the heart 80 per minute. Apparently healthy man with the exception of this discomfort— discomfort which was clearly that of minor angina. It wa only in the last 12 months that the symptoms had in an way forced themselves upon his notice, though, being a extremely careful man, he had sought advice with regar to them eight or nine years ago. In the end he was seize with major angina, which lasted off and on all through on day, ending fatally.

The following history of four brothers is wort recording as an excellent example of the familia liability and its importance, while it emphasises som of the points we have been discussing. The fathe died at 63—cause unknown. The mother died a 62 from a stroke. She had suffered from an initia stroke three years previous to her death. I hav notes of the four brothers, three of whom I have seen

In November, 1919, I saw J., the first, aged 60½. H complained of pain, epigastric in site, brought on by walking Five years earlier, when this pain first began, he was treate for indigestion. Latterly the pain had radiated upwar from the epigastrium into the jaws and throat, and to a poin just inside the left elbow. This last pain sometimes occurre independently of the thoracic disturbance. Systolic bloo pressure 160 mm. Hg, with pulsus alternans—indicating grave prognosis. He died suddenly in an attack of angin in December, 1921.

The second brother, A., aged 56, in February, 1920, con plained of "tightness on breathing," especially after walking and a sensation of a "swollen lump" under the left nippl "too big for the chest." Also of a pain which he ascribed t "indigestion" situated about the angle of the left scapul independent of meals but induced by effort. Pain sprea from this area into the left arm and down to the elbow He gave a history of syphilitic infection in youth, and h had noticed that the present anginal symptoms dated fro an attack of influenza in June, 1919. There was a moderat degree of arterio-sclerosis and the systolic blood pressur was 190 mm. Hg. Since Christmas last he has suffered fro an aching smart in the left arm and middle fingers, and i April his symptoms became more severe for a while especially the bursting sensation over the cardiac thrust The rate of the heart was then 72 per minute, the systoli and diastolic pressures 200 and 110 mm. Hg.

A third brother, T., aged 62, consulted me in December 1919. He was not conscious of any limitations; could dig walk, and work, but he was apprehensive because he knew that his three brothers suffered from anginal symptoms. could find nothing wrong. Heart normal, rate 88 pe minute, systolic blood pressure 150 mm. Hg; but in view of the family history I cautioned him against excessive effort Eleven months later, in November, 1920, he had two attack of terrible angina. He is still alive and feels in excellen health, and he has had no severe attack since that time, bu he has "reminders" if he hurries or is flurried. "A for of acute indigestion, if you understand me," was hi description, the pain being substernal about the level o the nipples. It passes away at once if he stands still.

The fourth brother is 61 years old; he has not consulte me, but his doctor tells me that for five years he has suffere from anginal pain in the left arm and in the beginning o June last he had a severe attack.

This is a remarkable series. The earliest symptom were of significance, also the sense of oppression cause by walking, the sensation of something too big for th chest, the pain about the angle of the scapula labelle indigestion, the epigastric pain brought on by effort and in one of the four, the dramatic and fata major attack preceded for seven years by varying manifestations of angina minor.

CONCLUSION.

I have attempted to review our position when aced by patients suffering from anginal pain, who sk to be told what the future holds for them. I ave tried to discover where help and guidance are to e found in estimating the mortality, knowing only oo well that there can be no certainty about the utlook. It is admittedly brighter, however, in roportion to the degree of sensitiveness of the entral nervous system and becomes correspondingly raver when evidence is obtained indicating disease r degeneration of the myocardium. The electroardiograph yields informative evidence of this ature, and it is found that the mortality in a series of atients is higher when certain well-defined deviations rom the normal electrocardiogram are present. gain, prognosis is often at fault because the signicance of some of the slight and earlier manifestations re misinterpreted. These minor anginas have ertain characteristics which should enable them to be ecognised for what they are—symptoms often unobrusive, yet significant, and only yielding up their secret careful cross-examination. They may be compared a gesture, slight but ominous, and full of menace.

A Lecture

ON THE

REATMENT OF DIABETES MELLITUS WITH INSULIN.

Delivered at the London Hospital on Oct. 15th, 1923,

BY O. LEYTON, M.D., D.SC., F.R.C.P. LOND.,
PHYSICIAN TO THE LONDON HOSPITAL.

IT is my intention in this lecture to relate my experiice, conclusions, and advice in the treatment of iabetes mellitus with insulin, based upon observations 100 cases. Up till now certain facts following the jection of insulin have been noted, but since the ost skilled physiologists hesitate in interpreting them, shall refrain from stepping where angels fear to tread.

Insulin injected into a normal animal diminishes the ercentage of sugar in the blood and the quantity of ycogen in the tissues, without causing any correonding acceleration in metabolism; it has been ggested that this is due to the katabolism of rbohydrate taking the preference over that of otein and fat. The injection of insulin into an animal prived of its pancreas leads to a fall in the sugar in e blood, which is accompanied by a rise in the spiratory quotient, showing that carbohydrate is ing oxidised. The addition of insulin to the blood rfusing a beating heart leads to an acceleration in e diminution of the sugar in the blood. The ultimate tion of insulin has not been determined, but it has en suggested that it consists in turning the α and β ucose into γ glucose, and that γ glucose is the only rm which the tissues can utilise. Before accepting is tempting theory the results of further observations ust be examined.

THE MAXIMUM ADVANTAGE TO BE OBTAINED FROM INSULIN.

To sum up—we have in insulin a substance which hen injected into a diabetic allows him to burn gar. The question we have to consider to-day is, w can this substance be used to the greatest vantage of our patients? In order to answer that estion I must remind you of the work done by Allen out ten years ago. His experiments consisted removing the greater part of the pancreas and serving the conditions which allowed life to be olonged. The conclusion he arrived at was at overwork of the pancreas led to deterioration that gland. This was an epoch-making disvery, the importance of which has not been lly appreciated, although it forms the basis of the successful treatment of diabetes mellitus. Most tissues tend to hypertrophy when given extra work, but so far the only tissue which has been proved to degenerate by overwork is the β cells of the islands of Langerhans in the pancreas. Allen showed that overfeeding overworked these cells. Many suspect, and some assume, that dextrose in the blood stimulates the cells, and that an excess of dextrose would therefore overstimulate and lead to their destruction. Clinical evidence supports this view. Therefore, if an attempt is to be made to arrest the disease in a diabetic, insulin must be used in sufficient quantity to prevent at any time a hyperglycæmia which will overstimulate the β cells.

THE LIMITS OF NORMAL BLOOD-SUGAR.

The sugar in the blood rises after a meal; therefore we must attempt to keep the range of sugar in the blood between two arbitrary limits. The lower limit is easily defined as that which does not cause symptoms of hypoglycæmia; the actual percentage of sugar in the blood differs in different people: comparatively few have discomfort until it falls below 0·08 per cent., but I have met three cases in which the symptoms developed whilst the blood contained a substance which gave a reduction equal to 0·25 per cent. dextrose. The symptoms of hypoglycæmia are protean. One of the first to appear is apprehension—a vague fear that something untoward is going to happen. Although this is very pronounced in some (even in men who have proved to be brave and able to face death without flinching), others pass through to later stages without developing apprehension at all. A sense of tremulousness, followed by a coarse tremor, exaggerated when fine movements are attempted, and leading to a general shakiness, is very rarely escaped. An attempt to write brings out the characteristic of this symptom; often it is followed by profuse sweating and a sense of intense muscular weakness along with palpitation of the heart. These symptoms may pass off without the administration of carbohydrate or may be followed by dizziness, incoherent speech, convulsions, and finally coma. The ultimate symptom of intense hypoglycæmia is coma and any or all the intermediate symptoms may be omitted. We do not know why one man is wretched with 0·08 per cent. sugar in his blood whilst another develops no symptoms when his blood-sugar is 0·06 per cent. Our endeavour is to prevent the blood-sugar falling sufficiently to lead to symptoms.

The upper limit is arbitrary. In my own practice I fix it at 0·15 per cent. because I have observed that in the majority of cases when this percentage is not exceeded the destruction of the pancreas is arrested. It is arbitrary, because no doubt there are cases in which 0·16 per cent. or even 0·17 per cent. would prove to be harmless. In medicine we have to recognise the idiosyncrasy of every individual patient, but until we have studied that idiosyncrasy we must treat him along the lines we have found suitable for the average. Let me explain. I have seen at least six patients who have owned to drinking over a bottle and a half of spirits daily for many years. One individual asserted that in South Africa he took 22 tots daily, but since he had been in England 18 made him muzzy. Now of these six individuals, examination failed to show in four of them that alcohol had damaged the tissues. The late Sir George Humphry recorded details of a series of 12 octogenarians, two of whom were habitual drunkards. My counsel to the four individuals was:

> "I am glad to be able to tell you that I have failed to find any evidence of disease in you, but that does not mean that if you continue to take so much alcohol you will not develop disease—most people do. To be candid with you, I must tell you that some people are almost immune from alcohol, and habitual drunkards have reached the age of 80, but at present we have no means of distinguishing those that are immune from those who are damaged irreparably; therefore, I advise you to cut down alcohol to 6 oz. of spirits daily."

The simile is fairly apt. I have seen people with a blood-sugar of 0·6 per cent. who, so far as one can tell, have had this excessive hyperglycæmia for years and enjoyed wonderful health. Until we have developed some method of distinguishing the vulnerability of the pancreas and other tissues to excess of dextrose, it may be wise to assume that 0·15 per cent. dextrose in the blood is detrimental.

Some authorities say that diabetes mellitus is often a progressive disease, even when a diet is arranged to keep the sugar in the blood normal. This is a loose statement, which conveys different meanings to different people. Those who take an occasional sample of blood from their patients four hours or so after a meal, and find it 0·12 per cent., have no right to state that the diet prescribed leads to a normal amount of sugar in the blood. Samples should be taken, at short intervals after meals, for two hours, depending upon the rate of absorption and the nature of the food given. When I state that the blood-sugar rises at no time above 0·15 per cent., I mean that samples of blood are taken after a meal containing one-third of the day's diet, and none rises above the limit.

Ideal Method of Control.

The ideal method of treatment necessitates the examination of samples of blood taken at various times of the day over a period of three weeks. In many cases this is not possible, and therefore it is my intention to describe two methods, one of which does not depend upon blood-sugar estimations. Perhaps the first question to arise is, Which cases of diabetes mellitus are suitable for treatment with insulin ? In my opinion all cases of true diabetes mellitus are suitable, but it may not be expedient to treat all with insulin. Conditions of glycosuria with hyperglycæmia other than diabetes mellitus may be treated with insulin without detriment and occasionally with advantage. It will lead to the sugar being utilised which would otherwise be excreted, but the benefit accruing as far as we know in cases of hyperthyroidism, glycosuria due to a pituitary tumour, or excessive activity of the suprarenal glands is not comparable with that in true diabetes mellitus.

Naturally one must exclude cases of glycosuria due to some cause other than hyperglycæmia. None of these present symptoms of diabetes mellitus such as thirst, polyuria, or wasting. When the facility for examination of the sugar in the blood is available no difficulty is met in the majority of cases, although now and then a diminution in the efficiency of the pancreas is discovered so slight that only the inexperienced can make up his mind whether there is any real departure from the normal. In these cases I think that it is wise to let the patient lead a normal life for a few months and then reinvestigate. But time does not allow me to go into detail on this question.[1]

A Makeshift Control.

When it is not possible to arrange for estimation of the sugar in the blood some makeshift method has to be adopted such as the following. Assuming that sugar which ferments easily with yeast has been found in the urine of a patient in a comparatively small quantity, say about 1 per cent., the patient is then put on a restricted diet containing about 20 g. of carbohydrate, 50 g. protein, and 100 g. fat—i.e., ½ oz. bread, 16 oz. vegetables, 2 eggs, 4 oz. fish, 3 oz. meat, and 3 oz. butter. The patient is kept upon this diet for four or five days, and then the sugar in the urine is re-estimated. If the sugar in the urine persists in amount over 0·2 per cent. the probability of the case being one other than true diabetes mellitus is considerable. The patient should then be put on a diet rich in carbohydrates, containing perhaps 200 g. per diem, and after two or three days the sugar in the urine is estimated again. If it is under 2 per cent. one may conclude that the case is not suffering from diabetes mellitus, and therefore will be unsuitable for treatment with insulin. A makeshift method of this kind will only prove correct in 70 per cent. or 80 per cent. People not suffering with diabetes mellitus but with a threshold in the region of 0·16 per cent. will be

diagnosed as suffering from true diabetes mellitu
I repeat that of course these cases in which ther
is great doubt do not present any of the symptoms
signs of true diabetes mellitus.

The next question is, in which cases is it expedien
to give insulin ? Amongst these, first come the recen
cases. All cases of diabetes mellitus of recent ons
should be given insulin in sufficient quantity
produce a hypoglycæmia for a period of several week
in order that the pancreas may be rested and its fun
tion restored. The second class consists of those wh
are unable to tolerate food sufficient to maintain th
weight of the body containing no excess of adipo
tissue. If a patient cannot take a diet representing
calories per kilogramme without the sugar in the bloo
rising above 0·15 per cent., insulin is essential for th
continuation of his life as a useful member of societ
The third class is the patients who can take more tha
25 calories per kg., but who find the diet very irksom
and their energy at a low ebb ; these should be give
insulin upon the strict understanding that they sti
have to keep to a rigid diet, but that the diet will
the less restricted the greater the amount of insuli
given. Each patient has to balance the benefit derive
from the insulin against the disadvantage of t
expenditure on insulin plus the discomfort of t
hypodermic injection. The fourth class consists
cases suffering from coma of diabetic origin.

DETAILS OF AUTHOR'S METHOD.

The details of the method I adopt are as follow
First an attempt is made to eliminate any source
infection. My observation recorded in 1917 has bee
confirmed by many ; the glycopyretic function
depressed greatly by bacterial toxins. A diet
arranged containing 30 calories per kg. body-weigh
for a patient weighing about 50 kg., 30 g. carbohydrat
50 g. protein, and 140 g. fat. This would not be a sa
procedure were insulin not available for administrati
if ketosis develop. Remembering that 58 per cen
of the protein is potentially carbohydrate, the rat
of fat to carbohydrate is 2·3 : 1. This has be
asserted to be a safe ratio to prevent ketosis, but th
assertion is true only if a proviso be added that
the carbohydrate in the diet is being utilised. W
may take the absence of glycosuria as evidence that
the carbohydrate is being utilised and therefore
glycosuria cease it may be possible to treat the patie
by diet alone. We may not assume that because t
glycosuria ceases, the diet adopted is suitable ; it
true that it is not wasteful in so far as the food is
being burnt, but if the diet lead to hyperglycæmia t
pancreas will be overstimulated and in time furth
deterioration will occur in the majority of cas
Assuming that the glycosuria persists, the patient
given 5 units of insulin before breakfast and aga
before the evening meal. Two-fifths of the tot
carbohydrate in the day's diet is given at breakfa
and another two-fifths at the evening meal.
pronounced glycosuria persist the dose of insulin
increased to 7½ units twice a day, and, if necessar
further increases are made until the glycosuria
controlled or the sugar in the blood is found to fa
below 0·08 per cent. shortly before lunch or towar
evening.

I should like to take this opportunity of emphasisi
the fact that hypoglycæmia is very harmless provid
it be recognised early, and that sugar be given by t
mouth or intravenously. I have grave doubts as
whether any case of diabetes mellitus can be treat
adequately with insulin without symptoms of hyp
glycæmia developing at some time.

If it be possible to examine the blood of the patie
at comparatively short intervals the insulin is graduall
increased or the time at which it is administered
altered until at no time does the sugar in the bloo
rise above 0·15 per cent. Occasionally it is found th
in order to prevent hyperglycæmia an hour after mea
a big dose of insulin must be given which subsequent
causes hypoglycæmia. The administration of t
insulin may be moved from half an hour to thre
quarters or even an hour before the meal ; if this do

---

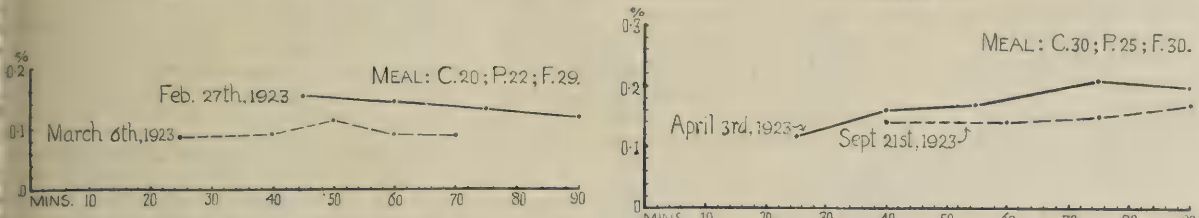
[1] Brit. Med. Jour., 1923, i., April 28th, p. 707.

not remedy the hyperglycæmia and the dose which prevents hyperglycæmia one hour after a meal causes hypoglycæmia two or three hours later, a small amount of carbohydrate, such as a biscuit, must be given about three-quarters of an hour before the time that the hypoglycæmia usually occurs.

RESTORATION OF PANCREATIC FUNCTION.

For a time the patient should be kept just free from symptoms of hypoglycæmia; this rests the pancreas. In a large percentage of cases (provided the dose of insulin and diet be kept constant) after weeks or months hypoglycæmic attacks will become more and more frequent, and may be prevented either by diminishing the insulin or by increasing the diet. Of the 16 private cases which I began treating in May, nine have had to reduce the quantity of insulin taken—some to about 30 per cent. of that required in June; one has not reported, and of the others circumstances did not permit me to submit them to a period of hypoglycæmia. This is undoubted evidence that treatment with insulin may lead to partial restoration of the pancreas.

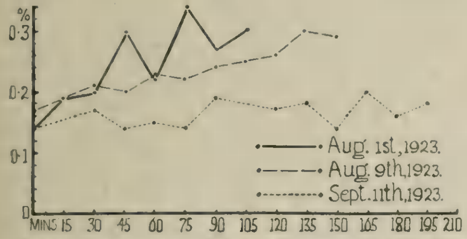
CHART 1. CHART 2.



Charts illustrating gradual restoration of pancreas and increase of glycopyretic power, as evidenced by concentration of sugar at different dates following meals of identical composition.

I should like to draw attention to other evidence leading to the same conclusion. In February, 1923, a young man who had developed thirst and polyuria a day or two previously was brought to me; insulin was not then available. The only way to rest the pancreas was by cutting down the diet and reducing the hyperglycæmia. The gradual restoration of the pancreas is illustrated by the two diagrams (Charts 1 and 2) showing the concentration of sugar at different dates following meals of identical composition. You will note that as time passed the glycopyretic power increased. Rest procured with insulin leads to the same result (Chart 3). A young woman suffering from severe diabetes was fasted for 18 hours, and then given intravenous injections of 10 per cent. solution of dextrose for three hours at the rate of 1 c.cm. per minute. Samples of blood were taken from the finger every 15 minutes. The curve obtained rose to 0·3 per cent. On repeating the observation a week later a similar curve was obtained. The patient was then submitted to treatment preventing hyperglycæmia for close upon five weeks, and the observation repeated. The blood-sugar did not rise above 0·2 per cent., demonstrating that the glycopyretic function had improved.

CHART 3.



Curves showing improvement of glycopyretic function after rest procured with insulin.

That the glycopyretic function may deteriorate if a hyperglycæmia be allowed to persist is proved by the hundreds of cases which have been treated by a restricted diet, and the diet gauged by the absence of glycosuria, with the result that the disease has made uninterrupted progress. An observation on a young patient in whom a hyperglycæmia persisted confirms this too (Chart 4). An identical method of introduction of sugar intravenously was adopted. The blood-sugar after an interval of a month's insufficient treatment rose to a higher level, showing a depression in the glycopyretic function.

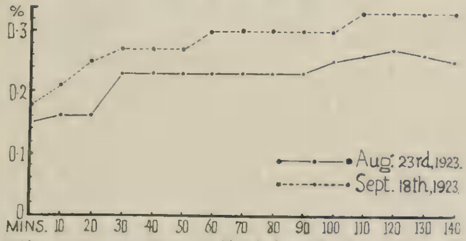
I adopted so elaborate a method as a long-continued intravenous injection of sugar because: (1) the absorption of dextrose when given by the mouth varies not only in different people but in the same individual from time to time, and hence intravenous injection was essential; (2) the continuous injection is to eliminate the time factor. If one were to give a series of injections one might miss the apices of the curve unless samples of blood were taken every minute, and a slight difference in the times would destroy the value of comparing two curves.

It is early days to draw conclusions, and I am the last to wish to appear dogmatic, but all the evidence at my disposal seems to point in the same direction.

TREATMENT WITHOUT BLOOD-SUGAR CONTROL.

If it be not possible to estimate the sugar in the blood, the same diet should be adopted as I have just described. Half an hour before the two main meals 5 units of insulin are given and continued for six days. If sugar persists in all the specimens of urine passed a gradual increase in the dose of insulin is made, about 1 unit a dose every third day, until most of the specimens of urine passed are free from glycosuria. When this is found to be the case the patient should be instructed in the symptoms of hypoglycæmia and told the remedy—namely, two lumps of sugar. The dose of insulin should then be still further increased very slowly until the patient develops definite signs of hypoglycæmia. If these occur four hours after the injection of the drug, it is probably wiser to give a biscuit three hours after the injection to ward off the hypoglycæmia rather than to reduce the dose of insulin.

CHART 4.



Observations on a young patient in whom a hyperglycæmia persisted, indicating that such persistence results in deterioration of glycopyretic function.

If the patient is free from glycosuria, and just misses hypoglycæmia by taking a small biscuit twice a day and persists in diet and dose unaltered, he will find that after a few weeks attacks of hypoglycæmia will reappear. Then a reduction in the dose of insulin should be begun and a gradual reduction be made until hypoglycæmia is just prevented. The absence of glycosuria is not to be taken as the method of determining the right ratio between the diet and the dose of insulin. In the treatment of cases without the estimation of the sugar in the blood it must be remembered that diabetes mellitus differs in one way from many diseases. Often symptoms assist in treatment, and when the patient feels better he is really better. For instance, an inflammation of the stomach causes the patient to lose his appetite, and if he eats he vomits; the stomach insists on rest. If a man eat an irritating material it is passed through the intestine rapidly and leaves the body. If the kidneys are diseased, appetite fails and the amount of work thrown upon them is diminished. But when the pancreas fails the symptoms are hunger and thirst, and everything seems to be arranged to hasten the departure of the stricken from this earth. Often he feels better when on a generous diet and with a high blood-sugar than when on limited diet with a low blood-sugar. So that some of the most valuable data in the treatment of other complaints are absent in diabetes mellitus. Therefore the practitioner who undertakes the treatment of diabetics with insulin must recognise this and recast his ideas on the relation between the details of treatment and the sensations of the patient.

The simile between the treatment of diabetes with insulin and the treatment of myxœdema with thyroid is not very apt. The variation of the activity of the thyroid from time to time is, as far as we can tell, only a minute fraction in the variability of the activity of the pancreas. Insufficient thyroid will not lead to progress in the destruction of the thyroid, nor will sufficient thyroid given by the mouth arrest the destruction of the surviving thyroid; and anyway there is no difficulty in supplying sufficient thyroid by the mouth even when the destruction of the gland is complete. Cessation of administration by the mouth will not lead to death within two or three days. The whole process has much fewer risks, and although it needs care the need is not so great.

I do not for a moment wish to imply that diabetes mellitus should not be treated with insulin even by the busiest practitioner; but I state definitely that there is little hope of getting the best results from insulin without the expenditure of much labour. Assuming that the patient is best off on a definite diet with 25 units of insulin twice a day, that patient will run less risk if he is on the same diet with 20, 15, 10, or even 5 units of insulin twice a day than on none. The proverb that half a loaf is better than no bread undoubtedly applies to insulin.

Having arrived at the dose of insulin required to prevent hyperglycæmia in a patient upon a definite diet, the patient may elect to add to his diet. This will need a fresh series of observations, and therefore it is wise for the patient to decide early upon what diet he will be happy, and how much he can afford to spend upon insulin. One of these factors must be fixed and the other altered to suit.

Unexpected Causes of Hypoglycæmia.

I have already expressed the opinion that everyone who treats patients with insulin, and everyone who receives insulin, should be acquainted with the symptoms due to an excess, or rather, due to insufficient sugar in the blood. The causes for hypoglycæmia are occasionally unexpected; for instance, one patient developed convulsions four hours after an injection of insulin, although for many weeks he had had the same dose of insulin and the same amount of carbohydrate, protein, and fat for breakfast. The explanation consisted in mental perturbation, which had paralysed his stomach and delayed the absorption of the porridge and toast which formed part of the meal. This mental condition arose from the excitement of a heated argument. I have seen symptoms of hypoglycæmia develop due to an excessive dose of an aperient, which has hastened the food through the intestine and prevented absorption. Anything which prevents absorption will lead to hypoglycæmia; if the pancreas goes on strike and ceases to secrete a starch-splitting ferment, severe symptoms may develop. When this is found to occur, carbohydrate must be given as sugar if the administration of diastase does not meet the difficulty.

Treatment of Coma.

The treatment of coma due to ketosis still causes anxiety, and no routine treatment proves successful in all cases. First let me impress upon you that coma is not due to an excess of sugar in the blood, whilst too little sugar may lead to coma. I have found 0·9 per cent. of sugar in the blood of a patient without his suffering from any symptoms whatever, whilst 0·6 per cent. may be maintained for a long time without causing anything more than neuritis and endarteritis. Therefore, if there ever be any doubt whether the patient is suffering from coma, due to ketosis or hypoglycæmia, sugar should be injected intravenously; that can do no harm, whilst an injection of insulin may hasten the end.

In my opinion a 20 c.cm. syringe ready charged with a sterile aqueous solution of 10 per cent. dextrose should be by the bedside of every patient suffering from coma when treated with insulin, and if the patient relapse into coma after having made an apparent recovery, the contents of the syringe should be injected very slowly into a vein. If the coma be due to hypoglycæmia the result is miraculous; the patient regains consciousness within a minute. If the result be negative, a second syringeful may be given. The continuation of coma after the introduction of 4 g. of dextrose indicates that the coma is due to ketosis, cerebral hæmorrhage, uræmia, or some cause other than hypoglycæmia.

Treatment of Ketosis and Digestive Disturbances.

The details of treatment are—first be satisfied that the coma is due to ketosis; the onset with air-hunger and the smell of acetone in the breath is very suggestive. Diacetic acid is, as a rule, in the urine, but not invariably. Estimation of the percentage of carbon dioxide in the alveolar air may be used to confirm the diagnosis. Usually it is found that it is under 2·5 per cent.—i.e., less than half the normal. A fairly large dose of insulin, say 30 units, should be given either hypodermically or intravenously along with 30 g. of dextrose unless the sugar in the blood be estimated straight away; then, if it proves to be above 0·3 per cent., no dextrose need be given. After an interval of three to four hours a second dose of 30 units of insulin should be given along with an intravenous injection of 30 g. of dextrose. This may be continued if necessary until the patient becomes conscious. As soon as the patient is conscious give lemonade containing sugar, so that he may receive 3 g. of sugar for every unit of insulin which is injected. Do not remove the syringe containing dextrose solution from the bedside, and give orders that if coma redevelop, whoever is looking after the patient must attempt to give the contents of the syringe. If the vein be missed and the sugar runs into the subcutaneous tissue, less harm will result than if treatment is delayed until the doctor be fetched. He would arrive in time only to write the certificate of "death—hypoglycæmia."

We have had evidence that hypoglycæmia may develop ten hours or more after the last injection of insulin, even when plenty of carbohydrate has been given by the mouth during the interval. The excess of sugar will be removed by the kidneys, and the extra damage done to the pancreas by overstimulation for an extra day or two is comparatively unimportant. Administration of large quantities of sodium bicarbonate is of little value.

The problem arises as to what to do if the patient loses his appetite or suffers from vomiting. The cessation of insulin, which at first sight seems to be a reasonable treatment, I have seen lead to the development of a ketosis in a patient who had become rather fat, and therefore, perhaps, it is wise to diminish the insulin and give approximately 2 g. sugar as a rectal injection for every unit of insulin. If along with the nausea and vomiting there be diarrhœa, then the insulin should be stopped. If ketosis develop intravenous injections of dextrose along with insulin are indicated.

As a rule the injection of insulin hypodermically is followed for a very short period by a sensation of stinging, which should be the only discomfort to arise. But in some people an inflammatory change which continues to increase for two or three days may be noted. In these cases it is wise to change the preparation of insulin. Often the antiseptic has some effect; different manufacturers use different antiseptics. Occasionally the inflammatory change is sufficiently severe to make the patient decide to cease the treatment. When this occurs, it is worth while noting the effect of intramuscular injection. The sites chosen should be those that are used for the injection of emetin—namely, into the erector spinæ muscles and the upper edge of the gluteus maximus.

THE PATHOGENESIS OF CEREBRAL DIPLEGIA.*

By JAMES COLLIER, M.D., F.R.C.P. Lond.,
PHYSICIAN TO ST. GEORGE'S HOSPITAL; PHYSICIAN TO THE NATIONAL HOSPITAL.

Dr. Collier began his address with a tribute to Dr. Little, senior physician to the London Hospital and founder of the Royal Orthopædic Hospital, for the accuracy and clinical acumen of his original monograph describing the disease, which was written nearly 80 years ago. Some of those who had written upon the subject since had written less clearly and the student of the present day often had but a hazy idea of the pathology of Little's disease.

It was in THE LANCET in 1841 that Little first called attention to the Influence of Abnormal Parturition, Difficult Labour, Premature Birth, and Asphyxia Neonatorum, on the Mental and Physical Condition of the Child, especially in Relation to Deformities. Little first established the incontestable fact that diplegia is often associated with abnormalities of birth, at the same time stating "it is obvious that the majority of apparently stillborn children whose lives are saved by the attendant accoucheur, recover unharmed from that condition." He theorised the lesion as a widely spread fine lesion of the cerebral substance which could affect one part of the brain more than another. He showed that the less severe cases may progressively recover in the course of years, thereby proving that the slighter degrees of the lesion were reparable, and lastly, he excluded gross injuries to the brain and gross lesions generally from the ætiology of the disease which bears his name, and pointed out its common association with microcephaly. Strictly speaking, said Dr. Collier, the term "Little's disease" should be confined to diplegia which is associated with difficult birth. Actually it is used by the French school of every variety of cerebral diplegia present from the time of birth. Brissaud strove hard to confine it to the paraplegia forms occurring in premature children.

He continued: Following on the work of Erb and Charcot in 1875 a heated controversy was waged as to whether the primary spastic paraplegias of childhood were of spinal or of cerebral origin. The battle went against the supporters of the spinal theory, and in the end, owing to the excellent work of Wolters and of James Ross, of Manchester, it became universally accepted that the lesion was cerebral in site. During this controversy much pathological material was collected, with the result that the anatomical finding was generally accepted to be an atrophy and sclerosis of the convolutions, remarkably symmetrical, sometimes general, producing a walnut-kernel type of brain, sometimes local and incident upon any part or parts of the convexity, but most often affecting the Rolandic region and in the paraplegic forms most noticeable in the paracentral region, without any sign of vascular lesion nor of meningeal involvement. This was the "lobar atrophic sclerosis" of the French school. It was recognised as the end-result of some previous pathological process, no explanation of the nature of which was forthcoming. The important fact was also emphasised that the degree of the atrophic sclerosis present often did not correspond with the severity of the clinical picture; the paralysis might be severe and the atrophic sclerosis slight. The French authors agreed that the symptomatology is determined by other than the anatomical condition as yet brought to light. In other words, the unknown initial pathological process may at the time of death be much more extensive than the atrophic sclerosis which follows in its train. The correctness of this conclusion has been supported by all the subsequent evidence.

The Case for Meningeal Hæmorrhage as a Cause for Diplegia.—In 1885 Dr. Sarah McNutt wrote a thesis upon this subject important not only on account of the excellence of her clinical report and pathological examination, but chiefly on account of her false deduction which aided by the support of Sir William Gowers had the most amazing and inexplicable effect upon public opinion as to the pathology of diplegia. It introduced a glaring error which has remained unto this day and which though pathologically untenable seems to have defied all the attempts which writers during the past 25 years have made to eradicate it. Dr. McNutt described a case of double infantile spastic hemiplegia in a child born with instrumental labour, who from the time of birth showed signs of very typical general spastic diplegia and which died at the age of 2½ years.

It is obvious that the pathological process in the brain had begun long before birth, from the primitive arrangement of the convolutions and from the condition of the pyramidal tracts. It was a typical condition of lobar atrophic sclerosis. Had Dr. McNutt remained content with her description of this case no harm would have been done. But she proceeded to refer to another case which she had published and figured, of a child delivered by the breech with easy labour, who from the fourth day onwards had severe convulsions and on the twelfth day began to develop left hemiplegia which became complete. Death occurred on the twenty-second day. Upon necropsy the left hemisphere was found normal, but the right hemisphere was covered by a clot which had broken up the central convolutions, the optic thalamus, and the corpus striatum, and which was only separated from the lateral ventricle by the ependyma. Dr. McNutt then lays down that "it is legitimate to conclude that had this second child lived it would have developed by cicatrisation the shrinkage of the central convolutions and the convergence of the neighbouring gyri which was found in her first case and which characterise the most marked cases of diplegia." She then generalises meningeal hæmorrhage as the universal cause for infantile spastic states dating from the time of birth and associated with difficult labour. And this opinion expressed by her has gained the widest acceptance, so that one reads on every hand that meningeal hæmorrhage is a proved cause of diplegia. Yet her case of diplegia did not date from birth, for the anatomical findings showed that the disease must have been installed early in fœtal life. And her case of meningeal hæmorrhage was not the result of difficult labour for the birth was described as having been particularly easy. It was not a case of meningeal hæmorrhage, but a large intracerebral hæmorrhage which ploughed up everything from the basal ganglia to the cortex, ultimately bursting upon the surface. This cerebral hæmorrhage did not occur at the time of birth, but 12 days after birth when the signs of the hemiplegia first appeared.

---

* Abstracted from a Presidential Address delivered to the Neurological Section of the Royal Society of Medicine on Oct. 11th, 1923. The address appears in full in the current number of *Brain*.

This is the whole evidence upon which the case for meningeal hæmorrhage as a cause for diplegia rests. Yet it is meningeal hæmorrhage which still catches the eye in the foremost place among the proved factors of diplegia in most text-books of neurology. Strumpell in 1885 brought forward undoubtable cases of post-natal diplegia and infantile hemiplegia due to polio-encephalitis, and he argued this initial pathology for infantile spastic states in general. There does not appear to be much evidence in favour of fœtal encephalitis, but it seems difficult entirely to refute the possibility.

Brissaud's Theory of Premature Birth.

In 1894 Brissaud started an entirely new conception of the origin of diplegia or, rather, of certain forms of diplegia, prematurity of birth. It is obvious, however, that the immense majority of prematurely born children who survive, complete the development of their nervous systems in good time, and do not develop Little's disease. The major incidence of premature birth in connexion with paraplegic forms of diplegia, though incontestably true is not universal enough to help Brissaud's argument, and there is the much more subtle explanation that the dyscrasia which produced the pyramidal trouble also caused the premature birth.

Meanwhile the steady accumulation of pathological evidence called for a conception of primary neuronic degeneration as the initial morbid process in diplegia. Cotard as early as 1868 drew attention to the atrophy of the pyramidal cells out of all proportion to the shrinking of convolutions and sclerosis. Warda in 1895 found absence or degeneration of cortical neurones in a case of pre-natal diplegia that was certainly not secondary to any sclerosis or other gross lesion. Mya and Levi in 1896 found arrest of neuroblastic growth with degeneration of such neuroblasts as had developed their processes. Some of the most severe of the pre-natal cases were found to have no macroscopic lesion at all, but an almost universal degeneration of cortical cells, pointing to the advent of a rapid degenerative change shortly before birth. Cases of post-natal diplegia with insidious onset and clinically identical with the pre-natal cases, two of which I published in *Brain*, 1900, were recorded having their onset throughout childhood even as late as the twelfth year (notably a remarkable case published in *Brain* by Campbell with onset at the twelfth year), and in all these cases primary neuronic degeneration was the lesion found. Further the occurrence of optic atrophy in about one-sixth of all cases made any other explanation than a primary neuronic degeneration difficult. Dejerine always supported a neuronic pathology, and he very rightly contended for a clinical and pathological separation between the diplegias and the double hemiplegias.

Freud's Theory.

In 1897 came the monograph from Freud of Vienna, which still remains the most complete and authoritative exposition of this subject. He seems to have been the first to use the term cerebral diplegia as indicating a bilateral symmetrical defect of the brain, not the result of gross lesions, in contra-distinction to the hemiplegias and double hemiplegias which he considered always to be the result of gross lesions. He argued, and indeed I think that he proved that all diplegia dating from birth, and which had been attributed to abnormalities of birth, really had its pathological origin long before birth in intra-uterine life. He piled up statistics to show that every writer upon this subject had admitted that 40 per cent. of all cases of diplegia dating from birth were without any possible factor in connexion with birth. He analysed most carefully the circumstances attending the difficult birth in diplegia, and he sums up in these words: "Premature, precipitate and difficult birth are not causal factors in the production of diplegia; they are only associated symptoms of deeper-lying influences which have dominated the development of the fœtus or the organism of the mother; the only cerebral paralysis which results from difficult birth occurs when the brain is lacerated, and this takes the form of a monoplegia or hemiplegia or rarely of a double hemiplegia, and the anatomical result of this lesion is entirely different from the findings in the brains of diplegia."

Freud brought forward reasons for linking up pre-natally installed diplegia with the cases which come on insidiously during childhood, at any age up to that of puberty, arguing a cause for primary neuronic degeneration of the brain which might be incident at any period of fœtal life or during childhood, and he cites some remarkable cases in support of this theory. The one distinction which at first seems to separate the congenital cases from the post-natal cases is the course of the disease. Most of the pre-natal cases tend to improve, some of them to a remarkable extent. The post-natal cases never improve, but progress more or less rapidly to a fatal issue while some few become arrested. Yet progressive pre-natal cases are known, and I have seen several of them, and both pre-natal improving cases and rapidly progressive post-natal cases have occurred in children of the same mother. It seems to me that there is every reason, both clinical and pathological, to think that they belong to one class of disease, in which a primary degeneration of cerebral neurones may occur at any period during fœtal and during adolescent life.

The Ætiological Factors of Diplegia.

I now turn to a consideration of the ætiological factors of diplegia, long lists of which will be found in all modern descriptions, with the remark that 40 per cent. of all the cases are without even the most slender causal antecedents.

Hereditary and Familial Influences.—These are exceptionally rare in the common types of the disease. Yet there are recorded instances in which a mother, who was the subject of pre-natal diplegia, has given birth to a child afflicted with the same disease, an example of which was reported by Oppenheim. Familial incidence in which pre-natal and post-natal cases occurred indiscriminately have been many times recorded, as in the reports of Krafft-Ebing, Feer, Newmark, and Pelizain already referred to. Post-natal cases of a progressive type with a heavy familial incidence have been recorded by Souques, by Pibram, and by Hochhaus, while this ætiology is also very obvious in the type of amaurotic family idiocy and familial spastic paralysis. Diplegia may also in rare instances be coincident in the same families with other degenerative diseases of the nervous system, notably hereditary ataxy and myopathy, and certain facts showing this relation have been pointed out by Koenig, Strumpell, Bernhardt, Franz Schultze, and by myself. Consanguinity of parents has occurred not rarely.

Maternal Ill-health During Pregnancy.—This factor has been placed in the most important position by many writers, and I think without any justification, so rarely is it met with. There is, however, one important exception, and that is the presence of syphilis. Its incidence is admittedly rare. Naef and Feer examined 179 consecutive cases and were unable to prove the presence of syphilis in any one case. Dejerine insisted that syphilis was only a factor in that it caused premature birth. Yet I have seen diplegic children with the most obvious signs of congenital syphilis, and so have many others. The most conclusive evidence is that in pre-natal diplegias, a condition of the brain is sometimes found in which granular ependymitis, decortication, and the general resemblance to the brain of general paralysis is so striking as almost to prove the point. What is needed is an examination of the Wassermann reaction in a long series of cases.

Abnormalities of Birth.—I have already excluded these conditions as causal factors and placed them as common, but by no means constant, clinical associates of diplegia, indicative of something wrong with the fœtus, or of something wrong with those mysterious elations between mother and offspring which deter-aine a speedy delivery at full time. My authority is, he inconstancy of these so-called factors, the insuper-ble difficulty of referring one and the same patho-ogical condition to such widely different causes as remature, precipitate, and prolonged birth and to sphyxia, the absence of any reasonable explanations r pathological findings to show how such events ould produce the disease, the opinion of modern riters upon the subject, and the complete negation rom the conditions of the brain found in every case.

Deductions from the Pathological Material.—It is emarkable that no lesions have been found in any art of the nervous system except in the cerebral emispheres. Since the brain increases in size and levelops during fœtal life by the evolution and levelopment into complete neurones of the neuro-lasts of which it is originally composed, the terms o frequently met with in the literature of this ubject, "agenesia" and "arrested development," imply mean that some harmful process has affected he brain during its period of development. I have ttempted to prove in my foregoing remarks that uch arrest of development due to an affection of he brain during fœtal life, and not to any event onnected with birth, is to be found in the brains of iost cases of diplegia in which the symptoms are resent from the time of birth. And I have further rgued that the first signs of the affection are expressed neuroblastic and neuronic death or degeneration.

If we liken the brain from the commencement of s development to a garden in early spring, well own with seeds—the neuroblasts—some of which erminate early, some meantime and some late, those erminating early perhaps of a hardier sort, those erminating late perhaps of a more tender kind, nagine what might be the effect of a noxious influence -a sudden sharp frost, for example, upon this garden. ccording to its severity and the time when it arrived, might, if it caught all the seeds in a condition of ermination and growth, leave this garden lifeless. r it might spare those seeds as yet ungerminated nd those seedlings which had attained sufficient rowth and robustness to resist its influence, and ffect only certain kinds of the seedlings perhaps ccording to the state of their development, to their eath and destruction. Or the seedlings affected by ne frost may not be all killed; some or all of them iay be simply "cut," and their leaves for the time ithered, and these may be able in some degree to new their growth and attain a maturity, in some ases perfect, in others stunted and imperfect, in all ases retarded. Lastly, this untoward weather may ontinue and crop after crop may perish in a progres-ive destruction. Some such process as I have put efore you in this homely simile of the seedlings nd the frost will, I submit, best serve to explain oth the ætiology, the symptomatology, and the athological findings in cerebral diplegia. This ypothesis will in a measure explain the restriction f the affection to the cerebrum, for this is the latest develop, the highest, and perhaps for these reasons he most vulnerable, part of the nervous system. t will explain the tiny brain of severe microcephalic iplegia, with no differentiation between grey and hite matter, and the most primitive type of convolu-ons, for here is widely spread neuroblastic death arly in fœtal life, with no myelination because no rocesses have been developed from the neuroblasts. will explain the strangely symmetrical and even rictly systemic affection of the cerebrum; the yramidal region alone affected, the frontal and ccipital regions alone affected, the parietal and frontal gions symmetrically involved, while the pyramidal nd occipital regions escape, the corpora striata alone ffected, as in the cases of choreic diplegia and con-nital athetosis examined by Anton and Demange. will explain those severe cases in which no signs f arrested development and little naked-eye change re found in the brain, for here the cerebrum has been ard hit at a time when its development is almost omplete. It will explain the progressive improvement of the slighter cases in the possibility of regrowth in partially or temporarily damaged neurones, and also those cases, both pre- and post-natal, which show a progressive degenerative course.

This hypothesis is not altogether original with me, though its development in this form is original. It was suggested to me by the writings of Brissaud on premature birth as the one and only cause for paraplegic diplegia. Premature birth was Brissaud's frost which cut the pyramidal seedlings. On my hypothesis it was the frost which caused both the premature birth and the pyramidal deficiency simultaneously. The cause of the initial process is entirely mysterious, as is the case also in so many degenerative nervous diseases, as, for example, the hereditary ataxies, myopathies, and progressive muscular atrophy. It may be of the nature of a toxic or of a deprivation process, and is likely to be of more than one variety. If there is any difficulty in the conception of such a cause acting for a time only, and subsequently allowing of regeneration of nerve elements, it is exactly paralleled by the neuronic affection of polyneuritis. If the action of the cause for a time only producing degeneration, followed by final arrest, is hard to believe, this is the invariable habit of the cause of peroneal atrophy, where the degeneration commencing at a certain period of life, progresses for a time, and comes always to a final arrest within comparatively narrow limits. The picking out of the systems of cerebral neurones by this disease may conceivably be due to the time of incidence of the essential cause, or to its physiological selective capacity for certain of the elements only, as occurs so commonly with poisons, or to a combination of these two events. And, further, the phylogenetic age of the several cerebral systems may be a factor.

I would put these conditions forward in explanation of the universal affection and of the various local affections of the brain which are found in diplegia: (1) The severity of the cause, which may affect all the cerebral elements indiscriminately, giving rise anatomically, and if acting early to a small primitive type of brain, destitute of neurones, and causing clinically a condition of idiocy with diplegia and blindness; (2) the time of development at which the cause is active, which may determine which systems are affected and which are spared, in the local atrophies of the brain; (3) the physiological selective capacity of the cause to affect some systems and not others; (4) a cause which may be temporary in its action and which for this reason only picks out systems which are vulnerable at the moment; (5) a cause which may be continuous in its action and which results in a progressive diplegia.

If my reasoning be legitimate, then we must class together all the clinical results which primary neuronic degeneration and its sequel general or lobar atrophic sclerosis produce, from microcephaly with idiocy alone, through the wide range of pre-natal and post-natal diplegias to the simplest forms of paraplegic rigidity. The one anatomical lesion which has been found in all cases of diplegia since it was first pointed out by Cotard in 1868 is disappearance of the neurones of the brain or degeneration of these. I hold that this is a primary degeneration of the neurons, and that it is the essential and primary lesion in all cases of diplegia.

Arrest of development of the brain and of its outgoing paths is often found. This is the natural consequence of the foregoing neuronic lesion when this occurs during the earlier periods of development of the brain, and consequently it only occurs in pre-natal cases. Atrophic sclerosis of the brain is the natural consequence of the neuronic decay. It is more marked the earlier in life the neuronic decay occurs and the longer the patient has lived after the degeneration has been installed. In some varieties of diplegia, of which the Waren Tay-Sachs type is an example, no sclerosis follows the neuronic degeneration, and this is perhaps due to a peculiar nature in the cause. Gross lesions are rarely found.

I submit that the essential anatomical cause of diplegia is a primary neuronic degeneration due to factors which are at present entirely elusive, with the exception of rare cases in which syphilitic infection of the brain is certainly the provoking agent. This conception of the pathogenesis seems to me to be compatible with all the pathological evidence which has been recorded, and to best explain the symptomatology and clinical aspect of this class of diseases.

THE OPERATION FOR
ELEPHANTIASIS SCROTI.

By H. W. L. WALLER, M.B., Ch.B., D.T.M. Liverp.,
SURGEON TO THE GOVERNMENT HOSPITAL, ZANZIBAR, EAST AFRICA.

This operation, which I have done for the last six years in Zanzibar, is a modification and simplification of that described by Fauntleroy, of America. The cases have varied very considerably in size and weight, 10 lb. being the smallest, 30 to 40 lb. quite common, and 91 lb. the heaviest. Earnest endeavours were made at first to secure absolutely aseptic results, but the situation and very nature of the elephantoid tissue rendered this ideal very difficult to realise, proper preliminary cleansing of the gnarled and knotted interstices of the skin being almost impossible, so that with the exception of a few cases a certain amount of suppuration has occurred at any rate in the line of suture. Fortunately, however, this makes no material difference to the ultimate very satisfactory result, nor is the duration of the convalescence noticeably prolonged, nor to be compared with the time required for healing with the old-time methods of performing this operation.

Partly by choice, mostly of necessity, I work single-handed, and beyond the assistance of one or two native hospital boys in supporting the tumour at the requisite times, no one touches the operation area but myself. Indeed, the operation being performed in the lithotomy position, an assistant would have difficulty in gaining access to the area, and would therefore not be of much use. Fauntleroy does not use a clamp or tourniquet, and in deference to his great experience the method was given a thorough trial, but the great convenience, the saving of time and of hæmorrhage achieved by the use of a screw-clamp at the base of the tumour have led me to adopt this form of tourniquet in every case. There are one or two pitfalls to be guarded against: first and foremost, the possibility of a scrotal hernia, single or double. In these pachydermatous subjects it is not always easy to determine if a hernia of long standing be present or not. If such a complication be found a radical cure should be effected and allowed to heal thoroughly before the scrotal tumour is attacked. Undescended testicle is quoted, but is a complication I have never met, and one which might surely be safely left alone when discovered.

Technique.

The patient lies in the lithotomy position, and the scrotum, which is completely enveloped in an improvised bag of aseptic material, is permitted to hang down over the bottom edge of the table. A large towel is wrapped around the tumour and one or two assistants lift the mass and drag it down in a horizontal direction. The clamp, which is of the simple double-bar variety, with butterfly nuts at each extremity, so that it can be tightened or loosened at will during the operation, is then applied, and adjusted as far up on the scrotum as possible, and as close to the patient's trunk as can be managed. It is screwed up firmly, and the tumour gently released and allowed to resume its dependent position; the dressings are removed, towels are adjusted and clipped, and a final generous application of tinct. iodi. to the mass completes the toilet. For a big case it is well to have at least half a dozen knives ready, as the gristly tissue easily turns the edge. The flaps are mapped out as follows: Starting on the right sid
about two inches from the middle line, and one in
from the junction of the scrotum and the abdomin
wall, that is, just below the clamp, a horseshoe-shap
incision is commenced, extending vertically downwar
over the scrotum until the level of the preputial openi
is reached, when the incision curves horseshoe-wi
to the left, passing below the preputial orifice. It
met by a similar incision which has started al
two inches from the middle line, and an inch below t
commencement of the scrotum on the left side, and t
horseshoe is complete. A distance of 4 to 4½ in. shou
separate the vertical limbs of the incision, for it is t
flap which is eventually to enwrap the penis.

A further incision is made at a right angle to t
right vertical limb of the horseshoe, extending in
lateral direction to the posterior aspect of the tumo
where it is continued round to meet the left verti
limb; thus, with the exception of the space betwe
the limbs of the horseshoe, this incision complete
encircles the tumour. The level of it cannot be exac
laid down, for in settling it three points must recei
due consideration: the first, that as far as possible o
sound skin should be left above the incision (this
generally, but not always, practicable); the secon
that from the sound skin left behind the new scrotu
is to be fashioned, and that in the new scrotum roo
must be found for the probably much thickened a
lengthened spermatic cords, and the testicles wi
their often abnormally dense coverings; and third
that even under sound skin much lymphoid tissue m
be found that can be, and must be removed, so th
what may appear at first an insufficiently extensi
flap, when denuded of its lymphoid and diseas
tissue, will be found to provide, when sutured, a m
capacious receptacle than was anticipated.

The next step is the raising of the horseshoe flap wi
its contained penis. Sometimes the organ will
found just beneath the flap, at others it must be soug
for deep in the lymphoid tissue. The vertical limbs
the horseshoe should be deepened, and the ma
grasped in the left hand and lifted gradually as it
released by the touches of the knife held in the rig
hand—the left all the while feeling for and protecti
the penis. The latter being found, and the gla
identified and protected by touch, at a distance abo
one inch distal to the glans a complete transver
incision is made through the flap, and the portion th
cut off is discarded. The glans can now be expose
and will be found with about 1½ in. of prepuce to
in a very dirty condition. It is wrapped in gauz
expressed, and thoroughly cleaned with dabs soak
in tinct. iodi., which, of course, are not used agai
It will now be found that about 4 in. of the horsesh
flap remain; this is denuded of all lymphoid tissue (
not denude it of its blood-supply as well) and then, wi
the penis, it is wrapped in gauze and thrown back
to the abdomen out of the way. We now search f
the testicles and cords. These are easily found, a
being dissected out free from the lymphoid tiss
surrounding them, and the gubernacula binding the
down to the scrotum, they are in their turn protect
with gauze and thrown up on to the abdomen. The
will usually be hydroceles on both sides. These a
opened and tapped in the usual way. If large, t
redundant tissue of the tunicæ vaginales is cut aw
and the edges sewn; if small, the tunicæ vaginales a
slit up, turned inside out and sutured with catg
behind the testicles.

It is now that the large mass may be cut away a
removed, after which a critical survey of the skin a
flaps left behind takes place. The latter are cleane
and freed from diseased tissue as far as possible. T
butterfly nuts of the clamp are gradually release
and bleeding points picked up; it is remarkable ho
few of these will need attention; with even the mo
massive tumours not more than seven or eight vesse
may require a catgut ligature, indeed, I have had cas
of weight in which not a single ligature was use
torsion of the few bleeding vessels presenting being a
that was necessary. The clamp being fully opened
removed. The silkworm-gut sutures are inserted

s well to begin at the most dependent portion of the otum, taking the median raphé as it leaves the rineum as the guide, and to continue to suture in at line until a pocket of sufficient size to hold the sticles and cords has been prepared. The penis and rseshoe flap are next sewn, the flap being wrapped ound the penis and sutured in the line of the absent phé ; the cut edge of the prepuce being sutured to the t edge of the skin now enveloping the penis after the anner of the ordinary circumcision. A few sutures d perhaps a little trimming are now required to close e flaps at the base of the penis and the upper portion the scrotum. After a big case, or if much lymphoid sue has unavoidably been left behind, it is sometimes advisable to leave a drainage-tube at the most pendent part for a couple of days. Oozing of thin ood-stained fluid may be expected after such cases, t it seldom lasts more than two days.

The patient can be got out of bed and encouraged walk a few steps after two or three days. Retention unknown. The operation is well borne, even by old anæmic subjects. It is most satisfactory to the tient ; I have not seen a recurrence ; and potency the rule afterwards so far as I have been able to certain. The mortality is nil.

Clinical and Laboratory Notes.

A CASE OF ALBUMINURIA OF PREGNANCY.

By Frank Cook, M.B., B.S., B.Sc. Lond., F.R.C.S. Eng.,
STETRIC AND GYNÆCOLOGICAL REGISTRAR, GUY'S HOSPITAL, BEIT MEMORIAL RESEARCH FELLOW ;
AND
Vernon E. Lloyd, *M.C.*, M.B., B.S. Lond.,
CHIEF CLINICAL ASSISTANT TO THE GENITO-URINARY DEPARTMENT, GUY'S HOSPITAL.

In view of the recent correspondence on this subject blished in The Lancet, it may be of some interest record observations on a case which has lately come der our notice.

A primipara, aged 23, first presented herself for examina- n at the ante-natal clinic, Guy's Hospital, on Oct. 26th. r last menstrual period terminated on March 31st ; the ght of the fundus confirmed this date. The fœtal head s freely movable above the pelvic brim (cephalic presenta- n) ; the position was left occipito-anterior. She com- ined of "morning sickness," but to this we attached no portance in the present connexion. On examination the ne was found to contain a considerable amount of protein, t no quantitative estimation was made at this time. r systolic blood pressure was 120 mm. ; she had no lema, and no abnormal symptoms other than the sickness. From Oct. 30th to Nov. 1st she was kept in bed on an linary diet. During this period no protein was found in e urine. On leaving her bed albuminuria subsequently appeared, and on Nov. 10th ureteric catheterisation was rformed at 11.30 A.M., after she had been up and about for o or three hours. The urine from the left kidney was more eply pigmented than that from the right ; the quantities tained over a corresponding period were 8 c.cm. (right) d 6·5 c.cm. (left). The protein content, estimated by ecipitation with trichloracetic acid in parallel samples of ne from either kidney and under similar conditions, was : *ht, 1·2 per 1000 ; left, 14·0 per 1000.* A few hyaline sts were found in the urine from the left kidney ; no pus ls or micro-organisms were found in either case.

On Nov. 16th and 17th an examination was made of urine ich had been passed on rising, and after she had been up two hours.

0 1.	Nov. 16th.	10.30 A.M.	8.30 A.M.	Nov. 17th.	10.30 A.M.
12 ..	Spec. grav. ..	1010	1014 ..	Spec. grav. ..	1015
0 ..	pH ..	6·6	6·2 ..	pH ..	6·4
3 ..	Protein ..	*1·8*	*0·5* ..	Protein ..	*2·0*

All these specimens contained a very few hyaline and anular casts ; no other abnormal constituent was found.

At 11 A.M. on the 17th blood was withdrawn from a vein l estimations were made of the bicarbonate and inorganic osphate content of the plasma. The bicarbonate was determined by the method of Van Slyke, Stillman, and Cullen.[1] A value of 0·0262 was found ; this is expressed as molar concentration of $NaHCO_3$ and may be compared with the average value of 0·0268 obtained by Cook and Osman[2] in cases of normal pregnancy. The phosphate content was determined by Briggs's modification of the Bell-Doisy method [3]; a value of 3·5 mg. phosphorus per 100 c.cm. was found, which is well within the normal range indicated by de Wesselow.[4] So far as these factors are concerned there was, therefore, no evidence of further renal defect.

Although it is very unusual for a pronounced albuminuria of pregnancy to disappear completely during a short period of rest in bed, these data in general correspond with observations which we have made in certain other cases. At the same time we do not wish at present to draw any definite conclusions, and would merely indicate an apparently promising line of research which we consider to be based on reasonable premises.

DEATH FOLLOWING INJECTION OF DIPHTHERIA ANTITOXIN

AND DUE TO STATUS LYMPHATICUS.

By Donald MacIntyre, *M.C.*, M.D. Glasg., D.P.H.,
MEDICAL SUPERINTENDENT, PLAISTOW HOSPITAL ;
AND
D. W. McKay, M.B. Toronto, D.P.H.,
SENIOR ASSISTANT MEDICAL OFFICER, PLAISTOW HOSPITAL.

The number of cases recorded of sudden death following injection of diphtheria antitoxin is so small that the following case seems of interest.

A boy, aged 10, was admitted to Plaistow Hospital at 11 P.M. on August 26th suffering from a severe attack of diphtheria. According to his history, he was in the third day of the illness, which had commenced with the usual symptoms of headache, malaise, sore-throat, and vomiting. His tonsils were greatly enlarged, almost meeting in the mid-line, and were covered with thick adherent membrane which extended to the base of the uvula and on to the post-pharyngeal wall. There was slight discharge from the nose. The glands at the angles of the jaw were hard and swollen. The heart sounds were weakened, but examination showed no other impairment. The throat culture gave a positive result to diphtheria. In a later history, obtained from the parents, it was stated that the patient had always been a delicate, nervous child but had never suffered from any serious illness. He always had a slight persistent nasal discharge but no other respiratory disturbance. They also stated that he always appeared to have some difficulty in swallowing.

Effect of Injection.—At 11.25 P.M. 18,000 units of antitoxin were injected by direct puncture into the right median basilic vein and 10,000 units were given intramuscularly into the right thigh. The patient's condition remained unchanged until 12.25 A.M., when the usual reaction following an intravenous injection of serum began to develop. He started to shiver, and the shivering soon developed into a well-marked rigor. His colour was blanched, the pulse small and rapid ; the temperature rose to 107·4° F., and he vomited once. During the rigor warmth was applied by means of additional blankets and hot-water bottles, the foot of the bed was raised, and stimulants and oxygen inhalation were administered. After 20 minutes the rigor subsided and his colour and pulse improved. He asked for a drink of water and wanted to sit up. His recovery from the reaction seemed quite satisfactory and he fell off to sleep.

Shortly after 1 A.M., however, the ward nurse was attracted by his stertorous and irregular breathing, and reported the condition. When examined he was found to be in a state of coma. The pupils were widely dilated and reacted only slightly to light. The breathing was stertorous, rapid, and irregular. Cyanosis was marked and the pulse could not be felt at the wrist. The heart was beating regularly but the sounds were weak. The temperature rose to 108·2° ; a tepid sponge reduced it to 103·6°. After about 15 minutes the breathing became quieter, the colour and pulse improved, and the patient moved his limbs but did not regain consciousness. Within a short interval another paroxysm of dyspnœa came on, lasting about 10 minutes, and from this time these paroxysms recurred at intervals of about 20 minutes. The patient vomited several times and fæces were passed in bed. No sign of a serum rash was discovered on any part of his body.

[3] Briggs, A. P.: Jour. Biol. Chem., liii., 13, 1922.

[4] De Wesselow, O. L. V.: Quarterly Journal of Medicine, July, 1923.

Oxygen inhalation was given continuously and doses of adrenalin, camphor, and atropine were injected. A nasal feed containing sod. bicarb. was given at 3 A.M. and retained. The patient, however, showed little or no response to treatment and his condition steadily became worse. At 4 A.M. he had a slight tonic spasm and from this time convulsions became frequent and increasingly severe. He died in a convulsion at 5.15 A.M.

Post-mortem Findings.—The body was poorly nourished, subcutaneous fat being small in amount There was a small curvature of the thoracic vertebræ to the left but no caries of the spine was present. When the chest cavity was opened the thymus gland was found enlarged and extending down over the pericardium. It was swollen and soft in consistence and weighed 35 g. The lymph glands of the tracheo-bronchial region were enlarged and were found in clusters about the size of small cherries. The mesenteric glands were even larger and more numerous. The superficial glands of the body were not hypertrophied. The lymphoid nodules at the base of the tongue were much enlarged. Peyer's patches were prominent and congested. The solitary lymph follicles of the small and large intestines were prominent and the mucous membrane of the cæcum and ascending colon showed marked congestion. The spleen was enlarged, weighing 170 g., and on section the Malpighian bodies stood out prominently. The heart was small, weighing 130 g. Its musculature was flabby and the right ventricle was dilated. No myocarditis was evident to the naked eye. The aorta was relatively narrow and thin-walled. The thyroid and suprarenal glands were normal in size and showed nothing unusual on section. The lungs were normal.

This patient received on admission the usual treatment for severe diphtheria. The reaction following the intravenous injection was very severe, but showed no unusual or alarming features; its course was similar to that observed by us in over a hundred other cases which had received intravenous serum during the past two years. When the patient became comatose the symptoms suggested a state of anaphylaxis, but after post-mortem examination we were satisfied that death was due to the condition of status lymphaticus

AN UNCOMMON CASE OF TYPHOID FEVER.

By ROBERT SWYER, M.R.C.S. ENG., D.P.H.,

SENIOR ASSISTANT MEDICAL OFFICER, NORTH-WESTERN HOSPITAL, LONDON.

THE following are the details of a case of typhoid of an unusual type.

The patient, a nurse at a fever hospital, was 23 years of age. Her illness commenced on Feb. 6th, 1923, with headache and sore-throat. She reported sick on the 8th with a temperature of 102·5° F., pulse 112, respiration 24. Tongue lightly furred; fauces, heart, lungs, and abdomen appeared quite normal on examination. During the night she had a rigor, and on the 9th complained of severe pain in back of head. The condition remained the same until the 12th, when the patient vomited twice, the attacks being quite sudden and not preceded by nausea. At this time it was noted that the right pupil was smaller than the left, but both reacted to light and accommodation, and there was no alteration in vision, the condition disappearing after a few days. Knee-jerks and plantar reflexes were normal and Kernig's sign absent. On the 13th 5 c.cm. of blood was taken and cultures made, resulting in the discovery of the presence of *B. typhosus*. Temperature dropped to normal on the 14th and remained down except for a rise to 100° on the evening of the 16th and to 99·4° on the 28th.

The pain in the occipital region, which was the only symptom complained of during the whole illness, continued until the 16th, when it finally disappeared. A second sample of blood was taken on the 22nd; the serum agglutinated a stock culture of *B. typhosus* up to a dilution of 1 in 160 and the bacillus previously isolated from the patient's own blood up to 1 in 80. *B. typhosus* was also recovered from the fæces on the 23rd. At no time was the rash of typhoid fever present. The spleen was not enlarged and there were no intestinal symptoms.

The only time the patient had been in contact with typhoid fever during the six weeks previous to her illness was on the night of Feb. 4th, two days before the onset of symptoms. She made a complete recovery and was discharged on March 6th.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

WAR SECTION.

A MEETING of this section was held on Nov. 12th with Air Commodore DAVID MUNRO, the Presiden in the chair.

Major A. T. FROST read a paper on the

Present-day Trend of Treatment of Gonorrhœa, with Special Reference to Cataphoretic Application of Colloidal Silver.

He said that since the discovery of the gonococcu many applications to the urethral mucosa had bee used in the hope of killing the organisms. Late when it was realised that no application could reac organisms buried in crypts, closed follicles, or beneat the surface epithelium, the routine procedure becam lavage with weak antiseptics and, more recently, th use of a number of metal instruments, some of whic were still of value in diagnosis or for destroying th local foci of disease which delayed cure. At th beginning of the present year the staff of the Militar Hospital, Rochester-row, decided to try two fres methods of attack on the gonococcus, (1) by the us of high antiseptics through the blood stream, an (2) by driving antiseptics into the deeper foci beneat the surface epithelium. The antiseptic employed i the first method was acriflavine (first employed b Lieut.-Colonel T. E. Harty at Dublin in 1921 0·2 g. of which was administered intravenously i 200 c.cm. of normal saline solution. On the fifth an tenth days 0·3 g. of acriflavine in 300 c.cm. of salin was similarly administered. During the course th urine was kept alkaline. In a small series of cas treated thus at the Royal Herbert Hospital, Woolwic in 1922, the average stay in hospital was rough 60 days. As, however, the skin became yellow a soon as the drug entered the veins, and the drug wa very rapidly eliminated, hypodermic and intramuscula injections were tried. These were, at first, no successful owing to the bulk of the injections an their acidity, which caused a local inflammator reaction. After further experiments on rabbits it wa found possible to make a more concentrated neutra solution (by adding 3·5 c.cm. of normal sodiu bicarbonate solution to 1 g. of acriflavine an diluting to 20 c.cm. with distilled water), 2 to 7 c.cm of which could be administered hypodermicall without causing great pain. Three doses were give at five-day intervals. This form of treatment, whic was still under trial, was found to give very encourag ing results, especially in chronic gonorrhœa—on case had apparently been cured and remained fre from recurrence for six months, by three injection after having resisted other forms of treatment for th same period. The neutral solution employed mus be freshly prepared every three days. Other dye might be discovered, but acriflavine was the best a a bactericide of those which had been tried up to th present.

Electrical Methods Using Colloidal Silver.

The production by Major S. H. Long of a pur silver colloid, stable in distilled water, provided th starting point of an electrical method of treatment The method first used was after the manner o ionisation, employing a silver catheter filled wit colloid in the urethra attached to the positive pole this method was abandoned owing to the pain and dis comfort caused by the catheter in the acutely inflame urethra. It was then decided to try the effect o using the colloidal silver cataphoretically—that is applying electric pressure and not electric curren through a column of colloidal silver within the urethra Electro-chemically the silver colloid consisted o electro-negative particles which actually moved (a could be observed under the microscope) throug the medium towards the positive pole when subjecte to an electrical pressure of not less than 60 volts. Cataphoresis aimed at driving these colloid particles nto the urethral mucosa by electrical pressure, since the colloid was a non-conductor of electricity. The technique employed in practice consisted of cleansing the patient's urethra and bladder and then filling them with colloid silver by means of an ordinary irrigation apparatus embodying a short ength of silver tubing in contact with the column of colloid. To this silver tube was attached the negative pole of a 106-volt direct current supply. The positive pole was attached to a wire gauze frame covered by washed lint moistened with saline, so shaped that when the patient sat upon it a prolongation grasped the shaft of the penis. With the voltage at zero, or "weak" on the sliding potentiometer resistance of the switchboard, the voltage is gradually ncreased until a pressure of 100 volts is registered, and less than one milliampère of current. It is hoped o control current by a "wireless" valve in circuit and prevent burns by an accidental short-circuit. The current was allowed to pass thus for 45 minutes on each of four successive days, and mmediately before the treatment was begun a ose of 20 million gonococcal vaccine was administered hypodermically. If, after four days, the rethra was free from discharge, the usual tests for ure were applied and the patient evacuated from ospital if he passed these satisfactorily. If discharge ersisted a second dose of vaccine was given and a Kohlmann's dilator passed to open up closed follicles; fter this cure could generally be obtained by one r two further "cataphoretic" treatments. The tests f cure consisted of irrigating the urethra twice a ay on two successive days with a 1 in 500 solution of magnesium chloride preceded by the injection of 00 or 200 million gonococcal vaccine and followed by he passage of a sound, urethroscopic examination, nd the examination of the urine and of prostatic nd vesicular secretion expressed by massage. The rine and secretions must be free from pus. As this reatment could deal only with a urethral infection, ases in which preliminary examination revealed isease in the prostate gland or vesicles received reatment with neutral acriflavine in addition to ataphoresis.

Major Frost then quoted the results obtained in 7 cases. On the average these cases received days' electrical treatment and were in hospital days, whereas the average stay in two venereal ospitals during 1922 was 69 days. This method of tack upon gonorrhœa was therefore very promising, nd work now in progress to discover the most fective voltage was expected further to improve he results. Other types of colloids are being vestigated.

Discussion.

Lieut.-Colonel P. H. Henderson was much mpressed by the results. Was the treatment as pplicable to women as to men?

Colonel Crawford Kennedy inquired what ze colloid particles were the most efficient, and hether relapse was frequent or the incidence of pididymitis increased by the cataphoretic treatment.

Squadron-Leader F. N. Smart had tried ionic eatment for nine months, using soluble salts of silver, pper, and other metals, but had not been impressed y the results. He inquired whether Major Frost's od results were not due to the acriflavine rather an the electrical treatment.

Lieut.-General Sir William Leishman pointed t that the electrical method employed by Major ost lent itself admirably to micro-experimental ork, using the colloid and a culture of gonococcus vitro, and observing the effect of electrical pressure d the consequent movement of the colloid particles on the organisms. Other colloids might be tried order to discover the most potent.

Lieut.-Colonel L. W. Harrison had felt that since e discovery of salvarsan the battle against syphilis as being won, but no such advance had been made the treatment of gonorrhœa. Major Frost's results were therefore all the more encouraging. Without wishing to detract from Major Frost's dramatic cure of chronic gonorrhœa with one injection of acriflavine, he yet could remember a similar cure of a chronic case by the mere passage of the urethroscope which had, he presumed, opened up a previously closed follicle. Were not the results of the colloid silver treatment in part due to the mere contact of the colloid with the urethra for 45 minutes a day? Local applications were of little value unless some means were employed of raising the bodily resistance, and of these a vaccine was the most effective. He noticed that Major Frost used only one dose of vaccine and inquired why this was not repeated.

Reply.

In reply, Major Frost said that there were no anatomical difficulties in applying the electrical method to women. The size of the colloid particles was of the order of 20 micro-microns and permitted them to pass through an "F" filter. The solution was concentrated by boiling. The killing of organisms might be ascribed to the bombardment by the colloid particles, and differed entirely from ionic medication. The particles are assumed to go deeper when subjected to electrical pressure, and the good results were not obtained in control cases which merely had the urethra filled with colloid without the current being turned on. Little microscopic work had been done, but other colloids were being experimented with. He used vaccines in order to increase the bodily resistance, and to open up closed follicles and thus render them more vulnerable to treatment.

The President congratulated Major Frost upon his paper and the results he had obtained. In the study of venereal diseases the medical officer in the Services, whose patients were a "controlled population," was able to work at an advantage when compared with civil practitioners, who consequently looked to the Services for advances in treatment.

SECTION OF OPHTHALMOLOGY.

Exhibition of Cases and Specimens.

A meeting of this section was held on Nov. 9th under the presidency of Mr. A. L. Whitehead.

Pseudo-Retinitis Pigmentosa.

Mr. H. M. Joseph showed a woman, aged 63, who had some of the signs of retinitis pigmentosa but none of the symptoms. There was the characteristic pigmentation, and in places there were choroidal changes. The fields showed an annular scotoma. The visual acuity in each eye, corrected, was 6/9. Night blindness was not present, and there was no associated condition in any other members of the family.—Mr. Montague Hine showed an example of a similar condition in a man who seemed to have monocular retinitis pigmentosa. The left fundus had been passed at the Pensions Department as normal; the field of that eye was quite full, and in the periphery of the field there was no ring scotoma. In the right eye the field was contracted to the 5 degree circle; his vision was 6/60 and 6/36. The man had an injury over the frontal sinus in 1918, and the exhibitor asked as to the possibility of such a condition resulting from an injury.—Mr. Cyril Walker spoke of cases collected by Mr. Jonathan Hutchinson, in which the condition, or a similar one, seemed to be a late sequel of injury.—Mr. Gray Clegg did not regard Mr. Joseph's case as one of retinitis pigmentosa, and did not think Mr. Hine's case was likely to have been due to injury.—The President said the irregular migration of pigment was very common in direct injuries to the eye; also following "windage"—i.e., when a shell exploded near, without any direct material impact. But he had never seen any appearance corresponding to that in Mr. Hine's case.—Mr. Affleck Greeves suggested that a condition as that of Mr. Hine's patient might be produced by an injury affecting the posterior arteries.—Mr. M. H. Whiting remarked on the difference of this case from those which showed concussion changes in the retina. He knew of no one who had seen damage done to the retina by windage. Mr. Hine's patient, in his opinion, showed a condition indistinguishable from retinitis pigmentosa.

Tuberculous Conjunctivitis.

Mr. P. G. Doyne showed a child with this condition, who came to hospital with a suppurating pre-auricular gland, which was opened. No other lesion had been found. A scraping of the lower lid showed no tubercle.—Mr. J. B. Lawford regarded the clinical appearances as very suggestive of tubercle, and advocated the X ray examination of the intrathoracic glands.—The President said that in some cases of tuberculous choroiditis and diseases of the conjunctiva, probably the primary cause was in the thoracic or the mesenteric glands, when no disease was obvious in cervical or other glands.

Mr. Basil Lang recalled Calmette's view that tubercle was acquired before the fifth year of life, remaining dormant in thoracic or abdominal glands until at some subsequent date malnutrition or disease brought it again into activity.

Dr. J. A. Valentine showed and described a pair of diving spectacles, and Mr. Rayner Batten explained the mechanism of the hydrophthalmoscope, which measured the normal vision under water without the aid of diving glasses.

The Treatment of Interstitial Keratitis.

Mr. Lindsay Rea submitted a preliminary report on this subject. He commented on the widely differing views on the matter held in the profession. He now submitted conclusions which he had arrived at from a careful observation and study of 91 cases, without regarding anyone else's notes on them. Very few workers on this subject had given the vision of the eyes after their courses of treatment. He had done this in his own series. The fellow eye could be found to be affected after even so long an interval as ten years after the first eye was involved. In his series there were three males to every female. Only two of his cases were over 26 years of age. The temporary teeth of these patients did not show any peculiarity. He had had a large number of children under 6 years of age who had not yet erupted their permanent teeth, and in them he had never yet seen healthy temporary incisors, some were carious, and even the gums were unhealthy. Many of the children were deaf. Congenital syphilitic deafness was labyrinthine, and several authorities regarded it as a hopeless form, as the lining of the canals was thickened, and the vessels were affected by obliterative endarteritis. Porter said that deafness often came on immediately after the onset of the keratitis, or else as it was subsiding. Any treatment which promised to help these patients was well worthy of consideration. Some thought that interstitial keratitis was the last manifestation of syphilis. He quoted a series of cases in which thorough treatment with N.A.B. cleared away syphilitic ulcerations completely, and others in which the eye condition was much improved by the same compound. By persevering with the treatment he had secured good results in the most unpromising cases. His practice was to follow up the N.A.B. with mercury.

Mr. Humphrey Neame said it was not common for syphilis to manifest itself after interstitial keratitis had cleared up. Of 39 cases on which he reported in 1921, 30 gave a positive Wassermann reaction. He did not agree that the majority of old cases of interstitial keratitis gave a negative W.R. In some cases there was a large phlyctenule at the limbus ; in others there was a deep folding of Descemet's membrane, probably due to œdema of the substantia propria. In one case the onset of the interstitial keratitis occurred two or three weeks after a blow which caused a black eye, and a few weeks later still the other eye was involved. Sometimes an operation, as that for cataract extraction, started an attack, although the healing from the operation had been complete.—Mr. Harrison Butler said the onset of interstitial keratitis after operation was not so frequent as he at one time supposed.—Dr. C. Worste Drought did not agree that interstitial keratit was necessarily the last manifestation of syphili In a case, aged 23, which had the eye conditio examined two years ago, the patient was no suffering from tabes dorsalis, of congenital origi In congenital syphilitics the blood Wassermann wa often negative, but they were very liable to show th colloidal gold curve of the luetic type. The latter wa a very valuable indication, as it might be the only or in tabes.—Mr. C. B. Goulden said the results treating interstitial keratitis with atropine were usuall so good that it was difficult to say, in a particular cas whether general treatment brought about improv ment in the eye condition, though admittedly benefited the general condition of the patient. O case of advanced congenital syphilis had choroiditi W.R. was positive, and extensive treatment b N.A.B., followed by mercury, was given. Subs quently the patient developed interstitial keratitis. The President said that for some years past he ha had all his cases of interstitial keratitis treated b galyl or similar preparations, and he was sure th present results were better than the former one He was sure cases were now seen earlier, and tha probably had much to do with the better results. was important to instil atropine, to prevent th formation of iritic adhesions, and to do all possib to raise the general health of the child ; he was in th habit of giving iodide of iron and other tonics. Mr. Rea replied.

HARVEIAN SOCIETY.

A meeting of this Society was held at the Tow Hall, Paddington, W., on Nov. 15th, Sir Cri English in the chair.

Sir John Collie opened a discussion on

Pitfalls of Medico-Legal Practice.

Many doctors, he said, were seldom called upon give evidence, and most of them disliked the expe ence, but there were means of making the latter little formidable as possible. He proposed to give few hints on the examination of medico-legal case It must be remembered that mistakes would n condemn a doctor, but the latter's conduct afterwar might easily do so. Mistakes should be admitted in any case they would be found out, and it was we to do the thing handsomely. The bedside mann should be dispensed with in the examination medico-legal cases, which should be a strictly busine transaction. The medical man should never prophe unless he knew. Judgment, skill, foresight, and eve experience were beads unstrung unless combine with infinite tact. In these cases the right pla for an examination was the consulting-room, whe the mental effect on the examinee was enormou A solicitor's office was the last place in which examine a case, and the Court of Appeal had decide that a solicitor was not entitled to insist on a doctor appearance there. Garrulous patients should encouraged, but it should be remembered that the were generally inaccurate. Taciturnity was a val able asset. It should not be forgotten that som women do not always do the exact opposite of wh was expected of them. Some resented every questio and some displayed very even tempers, because the were cross the whole time. Others would chatt about everything but the real question at issue.

Value of Painstaking Investigation.

To illustrate the value of thorough examinatio he quoted a case in which a clerk claimed to hav suffered concussion of the brain, when on duty, owin to the slipping of a mat which caused him to fa on a concrete floor. The patient was obviously i but there was no evidence of fracture. He (th speaker) was pressed by the medical attendant attribute the injury to the accident, but he thoug the patient had first become unconscious, and the fallen. He reported the case as not due to an accide ı duty. Six months afterwards the patient had ıother attack of unconsciousness, with no fall. he diagnosis was thrombosis of a vessel near one the visual lobes. The patient recovered and as taken into the army, but later he had vo fits of unconsciousness within ten days. oma set in and he died. At the post-mortem camination in France it was revealed that one teral sinus stopped short of the torcular Herophili, ıe dura mater being adherent to the brain, with no vidence of the supposed fracture. In another case e was asked to examine a woman who had a needle ı her hand, lying between the metacarpal bones, nd giving no trouble. He shook hands with the atient, and got a firm reciprocal and evidently ainless grasp, indicating recovery. The case went) court, and after long consideration the judge gave decision against the claim for disability to the and. Within a fortnight of the decision she was lmitted into a hospital for a huge open sore—ıalignant disease of the breast, which had gone ndetected on account of the omission to examine ıore than the hand. Nothing, then, should be taken r granted; more mistakes were made through ssuming things than through ignorance. For stance, a doctor told him he was asked to examine man who had let his insurance policy drop, and ished to be re-certified as in good health. He ripped and was apparently healthy in all respects. hree months later the doctor who examined him as asked by the insurance company why he had ıssed as a first-class life a man with malignant sease of the rectum, and who at the time of the camination had a colotomy opening. The examinee ıd covered with his hand an artificial anus in his odomen when being examined!

The Influence of Emotion.

The course of moral progress was spiral rather ıan straight. Motives were governed not by reason intellect, but by instinct, passion, sentiment, or notion, and we rarely knew of the existence of the eepest of these. The medical man should not tell ıe patient his opinion, but should reserve it for the licitor. Insurance companies were not interested or ıpressed by technical terms. Above all, the medical an should take notes at the time of the examination ıd preserve them. He was frequently challenged on ıis head. Even notes dictated and typewritten ımediately afterwards were sometimes disallowed. ı difficult cases the writing of the report should be ostponed for 24 hours, since perspective sometimes tered the view of the case. A medical man should ever be ashamed of changing his mind, but he ıould not change it after sending in his report. 'omen's instinct in the judgment of character was lmittedly marvellous; but intuitions were useless ı a court of law. It was useless to say that a man as a malingerer unless one had incontrovertible vidence of the fact. Moral victories counted for othing. In writing a report the emotion of mpathy should not be allowed to exercise any fluence. A statement of claim was usually made ıder the influence of deep emotion.

The Law of Libel.

All men were afraid of the law of libel, but if a octor were to do his duty he must express himself lly and fairly. Certain spoken and written words ere absolutely privileged—the words of judge and tness, the proof of evidence, and the medical report. ıe statement that a person was untruthful, fraudunt, or a malingerer was not libellous, if made in the ght place and honestly. He believed that anything ight be written by hand in England, but if even ctated to a secretary it became public and libellous. ı Scotland it was illegal to write the same statements, owever privately. Of county court practice, he und it difficult to speak with moderation. One arned to get used to it, and tried to enjoy it. The edical man in the witness-box must never get angry. ounsel was sometimes intentionally provoking, but ıe answers should be courteously given. If the doctor believed the case to be one of malingering, he should simply say that he had thoroughly examined the claimant, that the latter complained of many things, and that of those things there were no physical signs—and should leave it at that. The irresolution with regard to recommencement of work, which many patients displayed, should be emphasised.

Functional Nerve Disease and Trauma.

Erichsen's spinal concussion was a psychical condition. In organic disease of the spine, nature's warning was pain, which was followed by rigidity. If rigidity was absent, pain was improbable. Pain in the back was usually largely psychic, the alleged incapacity depending on an exaggerated idea of injury. Nine-tenths of subjective symptoms were the result of auto-suggestion. The art of medico-legal practice lay in determining how much was due to the neurotic outlook. Neurasthenics were facile, and their thoughts ran along the line of least resistance. Heart-to-heart talks helped, teaching the patient to take an optimistic inventory of his own mental qualities. The attitude of the artisan out of work for long periods was an interesting psychological study. The man lost the work habit; the earliest possible return to work was the best course. Immediate counter-suggestion applied at the right moment and frequently repeated was necessary. One overpowering idea excluded another—e.g., engaged couples were not pre-eminent for judgment; obsession had nothing to do with reason or logic. The medical man should not forget that his influence with the neurasthenic dwindled from the first time of seeing him. Suggestion, however, could not be practised as a duty; it required enthusiasm, which would succeed where other means had failed.

The Malingerer.

The erroneous evidence sometimes given by medical men was due to defective observation and memory, or to a lively imagination. One should never be in a hurry to diagnose a malingerer, and the latter's friends should be examined separately. To paraphrase well-known words, "better doubt all, and be deceived."

Discussion.

Mr. TRAVERS HUMPHREYS considered it very fortunate that members of the legal profession had been taught by Sir William Willcox to treat medical witnesses in the box not as partisans, but as experts. He had had little experience of county courts, but himself disliked them. He was prepared to accept the suggestion that about nine-tenths of the cases referred to by Sir John Collie were frauds. Cases in which he had heard medical men give evidence were chiefly criminal cases; there he had been delighted to observe that medical men were the only experts who could be entirely trusted to give truthful evidence. He confessed that lawyers were grateful to those members of the medical profession who practised as witnesses for their impartial evidence. The mistakes made by members of the Bar with regard to medical evidence were many. He hoped the day was far off when medical witnesses would come to be regarded as there to win or lose a case. He could understand the difficulties of medico-legal practice, and agreed that doctors should take careful notes at the time of examination. His own experience was that when medical men were held up to ridicule, it was on account of some little carelessness.

Sir WILLIAM WILLCOX said that his experience of medico-legal work was chiefly confined to the criminal courts. In the many cases, some of them hotly contested, in which he had given evidence, he had had every consideration from members of the Bar and from the whole court. As a medical witness he felt it important to encourage the feeling of mutual respect between the professions. There was pleasure in going into the witness-box to speak the truth with no feeling of anything pulling one way or the other, but he confessed to sometimes entertaining a hope that the accused would get off. The feeling of the far-reaching effects of statements made in the box caused one to be very cautious. He disliked cases where the defendant was not represented by counsel, or when counsel had not had time to get the case up properly. He welcomed a very thorough cross-examination in criminal cases. He had been struck by the remarkable facility with which members of the Bar picked up the medical points of a case, and recalled several instances of this facility, though confessing that he did not know how long the knowledge thus digested remained in the system.

Mr. **Ernest Clarke**, speaking from the point of view of an ophthalmic witness, urged the importance of speaking the truth and refraining from abuse of the other side. He told how in a claim against the London Omnibus Company he held that a claimant who had been knocked off his bicycle and found himself to be blind in one eye had always been thus blind without knowing it. By a coincidence, the judge, who admitted this view and gave judgment accordingly, had himself been blind in one eye for many years without having discovered it.

Mr. T. **Simpson Pedler** spoke sympathetically, from the lawyer's point of view, of the difficulty which arose for doctors in the delays encountered at the courts.

Mr. H. **Tanner** referred to a resolution passed many years ago by the British Medical Association advising that in cases where medical evidence was called on both sides, medical witnesses should meet and talk the case over beforehand. In compensation cases, he added, doctors sometimes found that they had difficulty in getting their fees. One colleague had told him that he had received no fees for the last five cases in which he had given evidence.

Sir **James Dundas-Grant** emphasised the importance of not "trying to be clever" in the witness-box, and spoke of the difficulties of certification of the insane and of the advantage of training in mental disease for students.

Other members also took part in the discussion.

Reply.

Sir **John Collie**, replying, expressed himself as much gratified by the discussion. He held to his contention that the class of evidence and advocacy in the county courts was exasperating, and much inferior to that of the High Court. Cases of gross exaggeration were trumped up, and it was the medical man's duty to hold firmly to his opinion. In his extensive experience of working men in medico-legal cases about 8 per cent. were distinctly malingerers. A talk between medical witnesses on opposite sides was always pooh-poohed by counsel. He spoke of the new Workmen's Compensation Bill shortly to receive Royal Assent, which would do away with much perjury in county courts. Either party would be able to claim that the case should go before a medical referee, whose finding would be absolute. As far as medical facts were concerned, many cases would thereby be prevented from coming into court. The medical referee would, however, have to make known not only his decision, but also his reasons for coming to it. He (the speaker) had obtained the insertion of a clause to this effect as the Bill was being considered in Committee.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.

A meeting was held at the Elizabeth Garrett Anderson Hospital on Nov. 13th, Dr. M. **Chadburn**, the President, being in the chair, when Dr. **Laura Veale** read a paper on

Spa Treatment at Harrogate.

She spoke of the stimulus given to hydrotherapy by the discovery of radium and the presence of radioactivity in water, and of the further impetus which was the outcome of the war. Hydrotherapy was now definitely established as a factor to be reckoned with in practical therapeutics. Dr. Veale discussed the special features of Harrogate as a spa—its geographical position on the highest table-land in England, its temperature, which was not so low as might be supposed, and its dry and sunny climate. Harrog
contained an exceptional number of mineral sprin
87 situated within a radius of two miles, and it
remarkable that each spring maintained an appro
mately constant composition while remaining che
cally and therapeutically distinct. She enumera
the composition and special value of the vari
springs, explaining which were suitable for inter
and which for external application, and deprecat
the habit of sending patients to a spa without c
fiding them to the care of a resident doctor. Mine
waters of any potency could not safely be taken
any time and in any quantity, and the results of
attempt on the part of the patient to treat him
often ended disastrously. As to diet, in Engl
spas the doctor had not the same advantages
on the continent of being able to superintend
patient's diet. The Harrogate Medical Society
again and again attempted to solve the proble
The difficulty was not so much with the hotel manag
or with the patients, as with the patients' frien
who refused to be content with simple diet. Patie
went to Harrogate suffering from many wid
different complaints, Harrogate being supplied w
springs containing both sulphur and iron water, a
equipped with facilities for all sorts of baths—sulph
peat, needle, heat, electric, paraffin wax, and whirlpo
among others—and also for special treatments, su
as the Ems system for throat and nose affectio
and the Plombières treatment for colitis.

Dr. M. E. H. **Morris** spoke of the

Waters of Bath.

She said that since Dr. Veale had dealt mai
with the clinical side of spa treatment she wo
refer briefly to the physical and physiological asp
of the subject. Important discoveries had been ma
in recent years as to the composition of the waters
Bath by the late Sir William Ramsay; and at t
present time research work was being carried on
the Mineral Water Hospital, which should result
increasing our knowledge of the physiological acti
of the waters. A municipal laboratory had also be
established in connexion with the Royal Unit
Hospital, where pathological specimens were examin
for the medical practitioners in Bath and the surroun
ing districts. The Bath water was always classified
a simple thermal water until 12 volumes of helium
10,000 volumes of the gases escaping from the Kin
Well were found by Lord Rayleigh. In 1903 Ramsa
working with Soddy, found that helium was one of t
products of the change of radium, and in the sa
year Strutt discovered radium in the Bath wate
Experimenters were unanimous in holding that t
effect of radio-activity was an increased activity
all the processes of nutrition and metabolism. The
was increased oxidation, as shown by a rise in t
percentage of all the urinary solids other than t
chlorides. Also, there was multiplication of the r
blood cells and increased activity of the digesti
ferments. The growth of bacteria was found to
retarded, if not inhibited, by radium emanatio
This was well shown at Bath by the marked succe
in the treatment of gonorrhœal arthritis. Also
was found that radium emanations stimulate t
elimination of toxins, as shown by increased toxici
of the sweat. An exacerbation of symptoms was
common incident of spa treatment, and if the reacti
was not severe it was usually welcomed as a sign
progress. Such reactions usually set in after a wee
or two of treatment, and were soon followed by
marked improvement. The conditions deriving mo
benefit from treatment at Bath were simple chron
arthritis, chronic muscular rheumatism, progressi
polyarthritis, infantile arthritis, and gonorrhœ
arthritis. Dr. Morris had had many patients sufferi
from subinvolution of the uterus and chronic pelvi
inflammatory conditions who had derived gre
benefit from the vaginal douches; while the Plon
bières irrigations of the large bowel had cured man
and relieved many other cases of colitis, constipatio
and post-operative adhesions. Treatment at Bat

contra-indicated for patients suffering from berculous conditions, also for those suffering from ntracted granular kidneys. The baths had been uch improved in the last ten years. Various different ads of bath had been installed, and an entirely new ectro- and physio-therapeutic department had been nstructed.

The PRESIDENT asked for details as to how ombières treatment was carried out at the spas.

In reply, Dr. VEALE said that Plombières treatment, applied at Harrogate, consisted of an injection of oz. of water at a temperature of 100° F., and at pressure of 2 ft. Copious lavage was not considered neficial.—Dr. MORRIS said that in Bath the Plombères treatment consisted of 20 to 40 oz. of water 100° F., applied while the patient lay on the left e. The patient then turned on to the back and right side, again to the left side, retaining the ection for a little while. Reports of the result re sent to the doctor by the attendant.

EST KENT MEDICO-CHIRURGICAL SOCIETY.

AT a meeting of this Society held on Nov. 9th Dr. LDRED CARLILL gave an address on

Tabes Dorsalis,

m cases at the Miller Hospital, Greenwich. His narks were based on the case-notes of 153 personally erved patients and were illustrated by a large nber of photographs taken by him. The importe of examining the pupils of all patients was phasised and the conditions other than syphilis in ich the Argyll Robertson pupil might occur were ntioned. Dr. Carlill gave an account of the early nptoms exhibited by patients. After discussing clinical and pathological examination, Dr. Carlill ed that the condition might often be diagnosed or to abolition of tendon-jerks, and he pointed that, whereas the tests in serum and cerebronal fever were always positive at some period of disease, they became negative not only in conion with treatment in certain cases but also in cess of time. Thus, it was not always possible to ain pathological confirmation of a clinical diagnosis abes dorsalis, but it was always possible in general alysis. Examples were given of the association of es dorsalis with other syphilitic conditions such basal meningitis, focal vascular lesions, or gummata, also with non-syphilitic diseases such as teria, lead palsy, alcoholic insanity, and epidemic ephalitis.

CARDIFF MEDICAL SOCIETY.

T a meeting of this Society held on Nov. 13th W. PARRY MORGAN gave a demonstration of the ssermann reaction and a flocculation test for hilis. He showed how the antigen was prepared n the heart extract, and exhibited tubes showing culation occurring when this was added to hilitic serum. He then showed the parts played complement and hæmolytic serum in hæmolysis, how this hæmolysis is used in the Wassermann tion. Examples of serum giving strong positive, k positive, and negative reactions were shown.

r. J. BEATTY read a paper on

Psoriasis.

the disease was familiar he did not deal with symptoms and course. He emphasised the emely small size of the initial lesion, and the that the spots grew at different rates, and that spots might occur while others were fading. sionally the lesion occurred at the site of wounds, as superposed on other skin diseases where there breach of surface; it persisted indefinitely, rrence being the rule. The occurrence of iasis was related to ill-health, for the dictum that as a disease of the healthy applied to about one-third only of the cases; further, it was not contagious, though very rare cases of apparent infection had occurred. He described the microscopical anatomy, as first distinguished clearly by Munro and elaborated by Haslund, showing that the primary lesion was a cell infiltration into the rete and accumulation beneath the corneous layer—a microscopic abscess. Later parakeratosis, or retention of nuclei, occurred here and there in the corneous layer with collections of shrunken leucocytes; acanthosis, or proliferation of the rete cells, was abundant, while in the corium there was widening of the vessels and accumulation of leucocytes round them. The pathology of psoriasis was unknown, investigators attributing it variously to a parasite, to a fault of metabolism, to some disturbance of the nervous system, or to one of the great systemic infections, tuberculosis or syphilis. Schamberg and his collaborators attempted to find a parasite, using complement-fixation methods and culture media of all varieties with and without the patient's serum, extract of the scales, &c., but were unable to isolate anything beyond the ordinary skin bacteria. Dark-ground illumination showed what appeared to be a bacillus, but Ketron later brought evidence to prove that this was a fibrin form. Inoculations on animals were equally unsuccessful. They also investigated the metabolism in psoriasis, using the amounts of nitrogen ingested and excreted as an index, and were able to prove that nitrogen retention occurred, but Tidy later showed that this occurred also in exfoliative dermatitis. It was now believed that this retention was due only indirectly to the disease, and depended on the desquamation. While the evidence for a parasitic origin was negative, there were no features which seemed to point to any other hypothesis which could not be equally well explained if the existence of a parasite were assumed. The microscopical anatomy and the spread of the spots by peripheral extension were strongly in favour of this, but it was necessary to predicate a predisposition—a suitable soil. Treatment could have only a temporary effect. Special diets did not appear to have any value. Locally, after removal of the scales, the tars, mercurials, and the chrysarobin group (including pyrogallol and resorcin) were the applications most used. Mercurials were the least effective and crysarobin most. Any application should be rubbed in. Chrysarobin was not an antiseptic tested against staphylococci, its action being that of a reducing agent, but its special value compared with other reducing agents depended (1) on its stability so that it was at full strength when applied, (2) on its ready oxidation by proteins and their derivatives, and (3) on the fact that sodium chrysophanate or other product of oxidation was quite innocuous. Sunlight, the electric arc, and X rays were all useful in special cases. The internal treatment was marked by the variety of the drugs used and the uncertainty of their action. These fell into six groups: (1) The arsenic group (including antimony); (2) the heavy metal group, mercury and manganese; (3) the iodides and thyroid; (4) carbolic acid, tar, and the volatile oils; (5) alkalies and salicylates; (6) vaccines and auto- and hetero-serums. Arsenic was the most reliable and usually successful in first attacks; it should be pushed to tolerance. Hypodermically or intravenously enesol seemed best, salvarsan being generally unsuccessful. Mercury and manganese were given hypodermically. The iodides were the next drugs to use if arsenic failed, thyroid being held in reserve. Salicylates had been given in large doses intravenously and salicin by the mouth. Vaccines, usually staphylococci, but often other germs, might be effective. Discussing the action of these drugs, the speaker pointed out that no physical or chemical relation between them could be discovered, and that they had to be administered in full doses. He believed that a pharmacological relation existed in that they were all tissue poisons. Even sera fell under that category, since symptoms resembling anaphylactic poisoning could be produced by first treating sera with physical agents. He strongly advocated the view that the really active body was some product of protein metabolism, and stated he believed this was true also of the treatment of syphilis, where unrelated substances like arsenic, antimony, bismuth, mercury, and even iron might be effective. The ineffectiveness of arsenobenzol on spirochætes in vitro might be explained in this way. The treatment of both psoriasis and syphilis seemed really a chronic poisoning, and the cure only indirectly due to the drugs used.

Discussion.

Prof. A. W. Sheen suggested that perhaps the cutaneous phenomena of psoriasis might be regarded as the local manifestation of some general disease comparable to the skin eruptions which occurred in systemic diseases like tubercle and syphilis. He also drew attention to the fact that psoriasis occasionally follows the distribution of a cutaneous nerve.—Mr. H. G. Cook discussed the seasonal variations of psoriasis. The disease was liable to exacerbations in the spring and autumn, the reason for this being obscure.—Dr. R. Prichard thought that heredity played a definite rôle in some cases, and cited instances. He described the successful treatment of a case by means of arsenic.—Dr. Gordon Greaves suggested that psoriasis might perhaps be akin to conditions of anaphylaxis, such as asthma and hay fever.—Dr. C. W. Shepherd, discussing the condition of nitrogen hunger, asked whether it was due to the scaling or was a peculiarity of psoriasis.—Dr. H. A. Haig inquired whether cases had been treated by Finsen light and whether X ray treatment had any value.—Dr. Beatty replied.

NEWCASTLE-UPON-TYNE AND NORTHERN COUNTIES MEDICAL SOCIETY.

A meeting of this Society was held in the Royal Victoria Infirmary, Newcastle-on-Tyne, on Nov. 1st. Dr. R. Esmond Moyes, the President, was in the chair.

Dr. A. F. Bernard Shaw made a communication on the

Pathology of the Respiratory System in Influenza.

He referred to certain data regarding the disease which had emerged from historical study and observations made in the last pandemic. Certain of these data bore more or less directly on the remarkable series of changes found in the respiratory tract, and could be adduced as evidence of the possibility that influenza did not fall within the category of a bacterial disease. It had been shown that epidemics and pandemics of influenza had affected man since the fifteenth century and probably earlier. It had frequently been described as a "new disease." Its manifestations were extraordinarily protean. The phenomenal rapidity of spread was unlike a bacterial disease and, in spite of the enormous amount of work done recently, there was no definite proof of its bacterial origin. No one had succeeded in inoculating healthy men with the disease. Probably no other acute disease so greatly lowered the resistance of the body to infection by bacteria as influenza. In the fulminating cases of the disease there was an intense tracheo-bronchitis with an aplastic exudate diffused throughout both lungs, and necrosis of the epithelium at all levels of the bronchial tree. Later, localisation of the process occurred together with a leucocytic reaction. At this stage there might occur as complications acute bronchiectasis, abscess, and gangrene of the lung. In those cases which survived a few weeks there was found extensive organisation of the exudate leading to obliterative bronchiolitis, obliteration of alveoli, and eventually fibrosis of the lung and bronchiectasis. As a result of this marked tendency to organisation it could be said that there was no other acute pulmonary infection which led to such distortion of the lung and impairment of function as influenza. Attention was drawn to the
remarkable capacity for epithelial regeneratior
the bronchioles which followed influenza, and sc
times the appearances almost suggested a
growth. The only lesions comparable to influ
were those produced in the lungs of animals
jected to inhalation of certain gases. Lantern sl
were shown illustrating the histological appeara
of the lesions.

Mr. R. J. Willan read a paper on

Perinephric Abscess.

He said that he would not include perinep
abscesses secondary to a tuberculous vertebra o
an acute appendicitis. He had collected 43 case
perinephric abscess where the records were mor
less complete. The anatomy of the fascia ren
was discussed, and emphasis laid on the fact t
below, the two layers of this fascia do not blend,
lose themselves in the loose areolar tissue of the i
region, thus establishing a direct tract between
abdominal true pelvis and the perirenal area. Of
43 cases the majority—namely, 26—occurred betw
the ages of 21 and 30, and the condition was commo
in males than in females. Twenty-four were rig
sided abscess, while the suppuration occurred in
cases on the left side. In considering the result
his observations Mr. Willan went on to say: t
the disease is commoner on the right side
thought to be due to the fact that the right kidn
with its surrounding perinephric fat, is lower do
and is therefore more liable to injury. Someti
perinephric abscesses are due to outward extensior
renal cortical abscess or infarct. Nine cases out
the 43 followed urinary sepsis, 8 followed trau
6 as a sequel to parturition, 3 to pneumonia, 2
recent boils, 2 to enteric fever, 1 to sacculitis of
colon, 1 probably to gonorrhœa, while in 10 ca
there was no stated cause. In 8 of the series—
18·6 per cent.—there was a definite history of
injury. My impression is that sudden tears
ruptures of the perirenal fat occur more often t
is generally believed. *Staphylococcus pyogenes au*
is the commonest organism found, then streptococ
then *Bacillus coli communis;* rarer organisms fo
are *B. typhosus* and pneumococcus. There are t
forms, primary and secondary. The primary fo
may follow injury, though more frequently it devel
after an acute fever, tonsillitis, boils, &c. Second
forms follow suppuration in adjacent organs,
infection travelling by direct extension or via
lymphatics. A feature of the complaint is in so
cases the length of the incubation period. The on
is often insidious, and in the great majority of ca
the onset symptom is a dull ache in the upper p
of the ileocostal space—i.e., just beneath the last
and lateral to the erector spinæ muscle. Occasi
ally the onset is acute, and then an onset rigor
often met with. Except in the acute variety, rig
are not common. Usually there is irregular fe
which is often mistaken for typhoid. With rega
to urinary symptoms, in 12 cases there were neit
urinary symptoms nor pus in the urine; in 11 ca
there were urinary symptoms together with pus
the urine; in six cases there were urinary sympto
without pus; in one case there was pus without a
urinary symptoms. Frequency of micturition is t
common complaint made, though four cases in t
series had renal colic. The symptom of thigh flexi
is common in this disease, and is due to the pe
nephritic inflammation spreading to the pso
muscle. With regard to treatment, an explorato
needle should not be inserted unless preparatio
are complete for immediate operation. Ea
drainage of the abscess is essential.

LIVERPOOL MEDICAL INSTITUTION.

A pathological meeting of this Institution w
held on Nov. 8th, Dr. Hill Abram, the Presider
in the chair. After the exhibition and discussion
specimens, Dr. J. Johnstone, of the Fisheri

Laboratory at Liverpool University, gave a description of a number of cases of

Tumours Found in Marine Fishes,

mainly cod, skates and rays, turbot and halibut. A few of these tumours were identified as cutaneous papillomas, cystadenoma of the ovary, angioma, and myxo-fibroma. Some were simple capsulated fibromas. The majority, however, were sarcomata. These were found in all regions of the body, but always in the same tissues. They originated in the subdermal connective tissue and spread along the fibrous septa that cross the body and give attachment to the systemic muscles. They spread by very active infiltrative growth, penetrating between the muscle bundles, and even between the individual muscle fibres. The latter atrophied and died over large regions. The sarcomata began as fibrous growths and then became highly cellular. Many were typically melanotic. There was difficulty in accounting for the multiple growths (or metastases) observed, by transport of tumour cells in the blood vessels, and it was more likely that the lymph channels are involved. The tumours led to great emaciation and finally death of the fish. There seemed to be no evidence of the origin of these growths by local irritative agencies, nor could traumatic injuries be assigned as possible causes. No instance of an undoubted carcinomatous tumour was found, although these were recorded by Gaylord and Marsh in domesticated trout and salmon. Some interesting questions were suggested by a study of malignant tumours in truly wild fish, and there was much need for extensive collection and investigation of all such conditions.

The paper was discussed by Profs. J. M. **BEATTIE** and E. **GLYNN**, and by Drs. T. W. **WADSWORTH** and R. **COOPE**.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

AT the first meeting of the session, held on Nov. 7th, the officers for the new session were elected.

Sir **ROBERT PHILIP**, the retiring President, recalled incidents in the life of the Society during his tenure of office. The Society had worthily fulfilled one of the main ideals of its founders—namely, "the bringing together in friendly rivalry and social intercourse the various workers in this rich metropolitan field of medicine." Sir Robert Philip continued: "If it may truly be said that in no city in the world does the profession of medicine occupy a higher place among the sister professions and the occupations of men, it may certainly be added that, in no centre and at no time have the intimate relations between the various grades of practitioners of the sacred art been more mutually serviceable and pleasanter than just now in this city of ours. . . . I cannot help suggesting that the happy condition is in large part the reflection of ideals that stirred in the mind of our first President, Andrew Duncan." Sir Robert Philip spoke of the numerous societies and enterprises of which Duncan was the founder, including the Edinburgh Hospital for Mental Diseases and the Edinburgh Harveian Society. The address concluded with a tribute to the two secretaries, Dr. W. T. Ritchie and Mr. W. J. Stuart, for their faithful and efficient work. Sir Robert Philip then resigned the chair in favour of Sir David Wallace, the new President.

Sir **DAVID WALLACE** thanked the Society for the honour conferred upon him, and in moving a vote of thanks to Sir Robert Philip, paid tribute to his great organising ability, displayed more particularly in connexion with tuberculosis. The vote was seconded by Prof. **WILLIAM RUSSELL**, and cordially carried.

Mr. **HENRY WADE** delivered a communication on the

Clinical Significance of the Form and Capacity of the Renal Pelvis.

He began by describing briefly the technique he employed in the practice of pyelography, emphasising the importance of preliminary preparation of the patient, whereby he came to the theatre with kidneys functioning actively. In no case was a general anæsthetic employed, as the conscious coöperation of the patient was necessary to indicate by his sensations when the limit of safe distension of the renal pelvis had been reached. He confined the practice of pyelography to in-patients. His present practice was to use a 20 per cent. solution of sodium bromide with which he had obtained the most satisfactory results. He had previously used collargol and thorin solution. In injecting the fluid he employed a 20 c.cm. Record syringe with a very accurately fitting piston, the fluid, suitably warmed, being introduced very slowly, so that any slight increase in tension could be appreciated by the resistance felt and the injection stopped when the least discomfort in the loins was experienced by the patient. In cases where previous lavage had shown a marked increase in the renal pelvic capacity, the distension limit was not sought for, but a measured quantity of fluid used. With the aid of lantern slides the interpretation of results was discussed and demonstrated. Some photograph of casts of normal and diseased pelves, made in fusible metal according to Cathcart's method, were shown, and various congenital abnormalities were demonstrated in casts and pyelograms. Mr. Wade estimated the incidence of single functionating kidney as 1 in 120. In cases of horseshoe kidney a bilateral pyelogram was justifiable, the pyelogram being characteristic and showing especially the unusual appearance of certain of the lower calyces which pass medially. He mentioned that although the unilateral fused kidney was fortunately of infrequent incidence, the importance of its recognition was great from the operative standpoint, and, as in those cases where the ureters were normally implanted in the bladder, its recognition was otherwise impossible; he always employed X ray ureteral catheters and took photographs with these in situ. In describing hydronephrosis he referred to the frequency with which operation in such cases revealed the presence of an abnormal renal artery to the lower pole without any evidence of mobility or prolapse of the kidney ever having occurred. He gave demonstrations of the appearances seen in chronic pyelitis. In referring to renal tuberculosis he said that, although the exact diagnosis could frequently be made without its use, the pyelogram gave a characteristic appearance, showing the normal calyces of the uninvolved portion of the kidney and the outline of the cavity where destruction of the tissue had occurred. In regard to renal calculi, he reminded his audience of the value of X ray catheters. The advantage of subsequent pyelography was demonstrated by cases showing calculi that produced total obstruction and others that permitted the entrance of the injected fluid into a pelvis distended by intermittent backward pressure. The importance of the routine practice of pyelography in all cases of suspected renal neoplasm was emphasised as affording an early indication of the disease by the destruction of certain of the calyces and the thinning and elongation of others at the site of the growth.

In the subsequent discussion, Dr. **CHALMERS WATSON**, Sir **HAROLD STILES**, and Dr. W. A. **ALEXANDER** spoke, and Mr. **WADE** replied.

Prof. **EDWIN BRAMWELL** showed a case of Thomsen's disease, and Mr. **JOHN STRUTHERS** a case of endothelioma growing from the membranes and destroying the frontal bones.

DONATIONS AND BEQUESTS.—The District Infirmary, Ashton-under-Lyne, will receive £500 under the will of the late Mr. George Henry Cooper, of Greenfield (Yorks.).—After several bequests the late Mr. Charles Simon, Whalley Range, Manchester, left the remainder of his property to the Manchester and Salford Blind Aid Society.—The Lord Mayor of Leeds has forwarded a cheque of £1000 to the Chairman of the Board of the Leeds General Infirmary in connexion with the war memorial of the Leeds City Police. This sum has enabled the endowment of a bed in perpetuity in the infirmary.

Reviews and Notices of Books.

Relativity.

A Systematic Treatment of Einstein's Theory. By J. RICE, M.A., Senior Lecturer in Physics at the University of Liverpool. London: Longmans, Green and Co. 1923. Pp. 397. 18*s.*

Relativity and Gravitation: An Elementary Treatise upon Einstein's Theory. By T. PERCY NUNN, M.A., D.Sc., Professor of Education in the University of London. London: University of London Press, Ltd. 1923. Pp. 162. 6*s.*

THESE two books prove that their subject has emerged from that phase of its history when its exponents were rather apt to brandish the weapon of relativity with such dazzling dexterity that they left the reader wondering more at the display of swordmanship than appreciating the sublety of Einstein's conception. All this in time is being corrected, and the two books are serious contributions to the subject from the student's point of view. They are, in fact, both written for the student, and we think it would not be a bad plan if students read the first 30 pages of Mr. Rice's book, and then turned to Prof. Nunn's for his four opening chapters. His subsequent choice we may no longer be concerned about, but he would by this means get about as much of the purely physical concept of the principle of relativity as is possible without settling down to rigid mathematical treatment. If he elects to do this he will get much help from either author; in the end he will probably get more from Mr. Rice, whose treatment of the subject is much fuller throughout. These books are valuable contributions to a subject that necessarily claims a big share in scientific thought.

Prof. Nunn says in his preface that his book should be well within the scope of anyone who has read mathematics up to, or nearly up to, the pass standard required for a B.Sc. degree. If it be true that the average candidate can pass lightly on to the geodesic law of motion and tensor-differentiation, we are quite willing to accept this statement as one further proof of the march of time.

Jacksonian Essay.

The Effects of Radium upon Living Tissues. With Special Reference to Its Use in the Treatment of Malignant Disease. By SIDNEY FORSDIKE, M.D., B.S. Lond., F.R.C.S. Eng., Surgeon to Out-patients, Hospital for Women, Soho-square. London: H. K. Lewis and Co., Ltd. 1923. Pp. 72. 5*s.*

IN this attractive essay the author combines a brief historical account of the effects which radium has upon living tissues with certain experimental and clinical results which he has himself obtained with this agent. The experimental results are those which followed the exposure of the ovaries of cats to various doses of radium radiation; the radium was enclosed in tubes, which allowed egress of practically only gamma rays, and by suitable operation was fixed near the ovary. It was left in position for selected intervals and subsequent microscopic examination of the organ revealed the main changes which had been set up. These are described in some detail and illustrated by some good micro-photographs. In common with other observers, the author finds the extraordinary degree to which the different tissues of the body react to the same dose of radiation. Unlike other authors, however, he does not distinguish between differential and selective action; they appear, in fact, to be used synonymously, for in this connexion we read "this differential action is shown more markedly in rapidly dividing and embryonic tissues, and it is upon this selective action that the clinical treatment of tumours is founded." The clinical results described are those obtained by the use of radium in the treatment of carcinoma uteri, cervix, vulva, vagina, and epitheliomata of the genital skin. In his conclusions upon the question of the efficacy of radium, the author expresses the opinion that in 80 to 85 per cent. of late cases the symptoms are relieved with the minimum amount of invalidism, and he raises the question: "Are we to continue to treat only inoperable cases?"

Included in the volume, though not part of the essay, there is a report on the treatment with radium of 45 cases of persistent uterine hæmorrhage in which the author claims an important rôle for radium, certain contra-indications, however, being noted.

Hæmorrhoids.

Their Ætiology, Prophylaxis, and Treatment by Means of Injections. By ARTHUR S. MORLEY, F.R.C.S. Eng., late Temporary Assistant Surgeon to St. Mark's Hospital for Cancer, Fistula, and Other Diseases of the Rectum. Oxford Medical Publications. London: Henry Frowde and Hodder and Stoughton. 1923. Pp. 120. 6*s.*

THIS handbook deals mainly with the injection treatment of hæmorrhoids. The author is a strong advocate for carbolic acid injection, and makes out a good case for his methods. He holds that all cases of hæmorrhoids can be successfully treated by injection, except those which are strangulated and gangrenous or complicated with fissure, and he lays proper stress on the great advantages of avoiding an anæsthetic and a period of lying up. Mr. Morley argues that injection does not produce thrombosis in the injected pile except as a rare occurrence, and this introduces questions which are not easy to answer. If coagulation in the dilated veins does not occur when carbolic acid is injected into them, what is the process of cure? Furthermore, in the absence of coagulation the dangers of absorption should be frequent instead of rare. The author criticises detailed operation statistics compiled from records at St. Mark's Hospital, and argues that the recurrence-rate after operation cannot be estimated by figures showing the percentage of the re-operated. Of course, the same may be true with regard to recurrences after injection. It would be salutary in many branches of surgery if individual results could be assessed—as they can be to a large extent at the Truss Society in the case of radical cure for hernia.

Blood Grouping.

La Individualità del Sangue nella Biologia, nella Clinica e nella Medicina legale. By Prof. LEONE LATTES, Director of the Institute of Legal Medicine in the University of Modena. Casa Editrice Giuseppe Principato, Messina. Pp. 174. L.18.

THIS little book is an extensive compendium and historical survey of the greater part of the work that has been done in blood grouping and its clinical and legal applications. It, moreover, embodies some of the researches of Prof. Lattes on the practical application of the agglutination test in the specific and individual diagnosis of human blood, the biological demonstration of paternity, and individual diagnosis of blood stains. There is a very extensive bibliography containing about 300 names, which include those of W. M. Happ and S. C. Dyke who have worked at the same subject in this country. The earlier chapters deal with the spontaneous reactions of individuality, iso- and auto-agglutination, the individuality of the blood as an hereditary factor, and consider also an ethno-anthropological view. Much useful information is to be found on these matters gathered from almost every possible source. A long chapter is devoted to the clinical application of blood groups with regard to transfusion from the point of view of incompatibility between the blood transfused and the individuality of he host. Another chapter treats of the medico-legal spects of blood grouping and describes more in etail Prof. Lattes's technique for the examination of lood stains, devised with the object of eliminating seudo-agglutination which is a source of error in ndividual diagnosis. We can recommend this book o those interested in this subject.

ULMONARY TUBERCULOSIS.

Die Lungenphthise. Ergebnisse vergleichender Röntgenologisch-Anatomischer Untersuchungen By Prof. S. GRÄFF and Prof. L. KÜPFERLE. Berlin: Julius Springer. 1923. With 221 illustrations, 10 photographic tables, 8 stereoscopic plates, and 3 coloured illustrations. Pp. 236. £2.

THIS work is published in two parts, the first ncluding the text, the second being devoted xclusively to the numerous and excellent illustrations. ne of the authors, Prof. Gräff, is professor of patho- ogical anatomy in Heidelberg, and the other, rof. Küpferle, is professor of internal medicine in reiburg. The guiding principle of their combined ork is to establish coöperation between the radio- ogist and physician on the one hand, and the morbid natomist on the other. To put this principle into ractice, they have together followed a number of ases from the hospital to the deadhouse, and most f their work is a detailed record of 52 such cases. he first part of this book is packed with clinical and athological detail, and the second part is an instruc- ive atlas showing side by side skiagrams and post- ortem dissections of one and the same case. Much bour has evidently been spent on this work, which hould be useful for reference to persons or institutions whom the expenditure of £2 is not an insuperable bstacle.

The Tuberculosis Worker. A Handbook of Methods and Programs for Tuberculosis Work. By PHILIP P. JACOBS, Ph.D., Publicity Director, National Tuberculosis Association. Baltimore, U.S.A.: Williams and Wilkins Co. 1923. Pp. 314. $3.50.

IN this most instructive book the author takes e reader behind the scenes and shows him every heel and lever of the complicated machinery which as made the organisation of the tuberculosis cam- aign in the United States a model of its kind. For he sake of convenience the book is divided into two arts. The first deals with methods, the second with rogrammes. "Methods" are classified according as ey are clinical or financial. There are also nursing nd institutional methods, and it is perhaps inevitable hat with this elaborate classification of subjects here should be a certain amount of overlapping. uch space is devoted to the organisation of publicity ampaigns, and advice is given as to how editors *hoc omne genus* are to be tactfully managed. It is lso pointed out that from 20 to 40 million people the United States do not regularly read the news- apers, and special provision must be made for ropaganda in this class. Interesting hints are given n the organisation of motion pictures and other hibits, and throughout the book the reader is given metimes quaint, but always helpful, advice with gard to the psychology of his fellow-beings. The berculosis worker must be all things to all men, d however enthusiastic he may be, he is not likely be highly efficient unless he has mastered his bject so completely that he has it at his finger-tips. uch has been written and spoken about coördinating berculosis work in this country; in the U.S.A. ördination in this field seems not only to be written d talked about, but to be an accomplished fact. his book has a message, not only to the whole- me tuberculosis officer, but to part-time workers, edical and lay, all of whom will find that tuber- losis machines, like clocks, must be properly bricated and wound up periodically.

JOURNALS.

JOURNAL OF PHYSIOLOGY. Edited by J. N. LANGLEY, Sc.D., LL.D., F.R.S. Vol. LVIII., No. 1. 1923. 10*s*.—Physiology of Plain Muscle: (1) The Effect of Alteration of Hydrogen-ion Concentration on the Tone and Contractions of Plain Muscle, by C. Lovatt Evans and S. W. F. Underhill; (2) The Oxygen-Usage of Plain Muscle, and its Relation to Tonus, by C. Lovatt Evans.—On the Absorption of Insulin from the Stomach, by L. B. Winter. It is known that insulin is rapidly destroyed by pepsin and trypsin in vitro, and it is probably for this reason, rather than inability of insulin to pass the intestinal wall, that administration of pancreatic extracts by the mouth have been relatively ineffective. In accordance with the fact that alcohol is absorbed from the stomach and water is not, weak alcoholic solutions of insulin were introduced into the stomach of rabbits previously accustomed to the absorption of alcohol by gradually increasing doses on successive days, until 4 or 5 c.cm. of 95 per cent. alcohol, suitably diluted, could be absorbed without interfering symptoms occurring as a result of the alcohol. Blood-sugar determinations were made by Bang's method—the blood being obtained from the marginal vein of the ear. It was found that insulin in weak alcoholic solution and administered per os causes the blood-sugar to fall to low level, and this effect was not observed when similar amounts of insulin were dissolved in normal saline, or in N/20 NaOH.—Does Insulin Influence the Glycogenic Functions of the Perfused Liver of the Turtle? by E. C. Noble and J. J. R. Macleod. Turtle liver is chosen for the study of glycogen formation because its main blood-supply is carried to each of its two lobes by separate branches of the umbilical vein. The remarkable effect which insulin has in causing glycogen to be deposited in the liver of completely diabetic (depancreatised) dogs fed richly on carbohydrates would seem at first sight to indicate that a part at least of the sugar which disappears from the blood of normal animals following insulin is due to glycogen formation. But such a conclusion is not justified in the absence of direct evidence that glycogen is formed in the normal animal under these conditions. It was found that varying concentrations of insulin in the perfusate did not influence the rate of sugar output from the excised liver, neither immediately nor after a period of 90 minutes. The conclusion arrived at is that the rate of post-mortem glycogenolysis in excised turtle liver is not influenced by the presence of varying concentrations of insulin at ranges of pH between 7·0 and 7·4.—The Rate of Recovery of Nerves in Asphyxia, by Sybil Cooper. Experiments carried out on the sciatic-gastrocnemius preparations of frogs show that the nerve does not require oxygen for the actual transmission of the impulse or for the recovery of excitability and conductivity. Oxygen, however, is necessary to remove the breakdown products formed during the passage of the impulse, so that the next impulse may find an adequate local supply of energy for its transmission. —On the Ovarian Factor Concerned in the Occurrence of Œstrus, by F. H. A. Marshall and W. A. Wood. The experiments were conducted on three bitches. The ovaries having been exposed, all the Graafian follicles visible on the surface were cauterised a short time before the œstrus was due. It was found that the heat period was missed and there was a prolonged period of anœstrum which might extend over the duration of two or more œstrus cycles. That the uterus did not atrophy was shown by the subsequent reappearance of heat and the resumption of normality. If, however, the follicles were only cut into without being destroyed, heat was not postponed or only slightly so. The general conclusions reached are that proœstrum and œstrus are due to an internal secretion of the ovary produced by the follicles during the pre-inseminal stage of development. Uterine and mammary hypertrophy during pregnancy and pseudo-pregnancy depends on another secretion, that of the corpus luteum. The normal nutrition of the uterus is maintained by yet a third internal ovarian secretion, produced by the smaller follicles or by the interstitial cells. All three secretions probably differ from one another qualitatively as well as quantitatively.—The Regulation of Respiration, by Thomas Lumsden. The three lower respiratory centres are regulated partly by chemical conditions—lack of O_2 and excess of CO_2—and partly by nervous influences—mainly vagal and trigeminal. (1) The "gasping centre" at the nœud vital is stimulated more powerfully by a combination of chemical factors, while the vagus has an inhibitory effect. Vagotomy invariably tends to liberate gasps. (2) The expiratory centre is merely impaired by oxygen-lack, and vagal stimulation is inhibitory. Vagotomy releases and prolongs active expiratory movement. (3) The apneustic centre, situated at the level of the striæ acousticæ, is stimulated by excess of CO_2 and by a moderate lack of O_2. Severe lack of O_2 causes the inspiratory tonus (apneusis) to fail and so indirectly as well as directly liberate gasping. Vagal stimulation inhibits apneusis, thus on occasions allowing the "gasping centre" unrestrained activity. Thus the effect of vagal stimulation on these centres is a tonic one in accelerating the rhythm of respiration and in diminishing the respiratory movements. Vagotomy, on the other hand, slows and deepens respiration.—Nerve Regeneration from One into the Other of Two Rats United in Siamese Pairs, by B. Morpurgo. If the rats are united parabiotically no nervous connexions are formed between them. To verify if this was due to the incapacity of the nerves of one individual to grow into the other, artificial nervous connexions were made in Siamese pairs of rats as follows: The cut end of the proximal stump of the right sciatic nerve of the left-hand rat was brought into apposition with the cut end of the distal stump of the left sciatic nerve belonging to the right-hand rat; whilst the proximal portion of this nerve was torn away from its roots. On the seventh day the connected nerve stumps were surrounded by recent granulation tissue, and outgrowing fibres from the axis-cylinders of the central stump had nearly reached the granulation tissue. On succeeding days the newly-formed fibres advanced into the peripheral stump and on the twentieth day had reached the popliteal space. Between the forty-fifth and sixtieth day they had reached the periphery, when they formed new end-organs. The regenerated motor end-plates were super-abundant and the regeneration of the nerve-endings took place in both rats. Muscle-spindles and neuro-tendinous organs also regenerated. Physiological experiments showed that after one month and a half motility, sensibility, and reflexes appear again in both legs; the contractions of the muscles in the right-hand rat can be caused by stimulating the sciatic nerve of the left-hand rat near the exit of the nerve from the pelvis; after two months and a half cross-end reflexes also appeared.—The other papers are two by J. N. Langley on Antidromic Action, and on the Vascular Dilatation Caused by the Sympathetic and the Course of Vaso-motor Nerves; an Ergometer Adaptable for Either Hand- or Foot-movements, by E. P. Cathcart, G. M. Wishart, and J. McCall; Colormetric and Electrometric Methods for Hydrogen-ion Concentration of Blood, by Ruth Conway-Verney and L. E. Bayliss; A Possible Relation Between the Pancreas and the Parathyroids, by L. B. Winter and W. Smith, in which it is shown that after a preliminary injection of parathyroid extract into rabbits convulsions are induced following one-third to one-quarter the normal dose of insulin.

Reports and Analytical Records.

BOVININE: A RAW FOOD EXTRACT.

(New York: Bovinine Company; London, J. D. Bishop, 22 and 23, Great Tower-street, E.C. 3.)

More than 30 years ago our analysis of this concentrated form of beef, which is prepared on scientific principles, showed an albumen content of as much as 16·96 per cent., calculated on nitrogen, with total organic matter of 17·77 per cent.; the mineral matter consisting chiefly of iron and phosphoric acid was 1·43 per cent. The food value of the extract is therefore high and many years of trial have confirmed its value where a nutrient capable of easy assimilation is indicated. Both with adults and infants good results have been obtained in illness, and in convalescence, especially in cases of gastric disturbance accompanied by loss of appetite and anæmia, the preparation has been found useful. The dose for an adult is half to one teaspoonful, gradually increased to a tablespoonful, either before or after meals and on retiring at night; it should be well diluted in milk or water, but other diluents can be substituted to meet the case. The dose for an infant is 5 to 10 drops in the food or mixed with barley-water; in this way it can be given at frequent intervals.

ZINC OXIDE RUBBER ADHESIVE PLASTER.

(Messrs. Edward Taylor, Ltd., Salford, Manchester.)

The gently astringent action of oxide of zinc on raw surfaces is well known and its application in connexion with adhesive plasters is an advantage in suitable cases. Messrs. Taylor, Ltd., supply, in spools containing 5 or 10 yards respectively and varying from $\frac{1}{4}$ inch to 4 inches wide, a rubber zinc oxide adhesive plaster which is a very effective form of application. It is antiseptic, non-irritating, and adheres without heat or moisture, while the flesh-coloured cloth on which the plaster is spread has a certain cosmetic value.

SCILLAREN.

(Sandoz Chemical Company, Ltd., Bradford.)

Scillaren is a glucoside of squill and is supplied in tablets, solution, and ampoules. The action of squill is well known to resemble that of digitalis, but some constituent of squill, when excreted by the bronchial mucous membrane, acts as an expectorant. A stable preparation, supplied in convenient forms, will be found useful in the many conditions where the drug has been satisfactorily employed for something like a century.

PINEOLEUM.

(American Drug Supply Company, 40–42, Lexington-street, London, W. 1.)

We have received samples of Pineoleum Brand Inhalant which has been found by laboratory tests to be a standardised preparation, and to exert inhibitory action on various micro-organisms. Pineoleum has been sprayed upon the surface of culture-media contained in Petri plates and previously inseminated with test organisms, a sufficiently fine spray being obtained by the nebuliser provided with the drug. Slightly less than 0·25 c.cm. of the fluid was sprayed on the culture-media in each experiment. Petri plate cultures, prepared with test organisms under exactly similar conditions, but to which the Pineoleum had not been applied, being used as controls. The controls and the sprayed cultures were incubated for three days at 37·5° C. before the final readings were made. The results showed Pineoleum to have certain inhibitory properties in regard to the meningococcus and the Klebs-Löffler bacillus, while with the *Bacillus influenzæ* the action was apparently marked. A convenient form of nebuliser is supplied by the company, so that spraying into the mouth and throat is rendered easy, and the use of the preparation in this manner has been followed by relief in coughs accompanying influenza. The inhibitory action suggests that Pineoleum can be used as a preventive measure not only in influenza but in other communicable conditions.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 24, 1923.

CONVALESCENT CARE.

With a widening conception of the laws governing public health, the public is coming to realise the importance of minor degrees of disease as factors productive of much individual and national distress. The increasing number of patients who seek advice at the out-patient departments of our great hospitals points, not to a greater incidence of disease, but to this appreciation of the value of treatment as a preventive, or as an aid to speedy recovery once the acute stage of an illness is over. The medical profession has long insisted upon the need for prophylaxis, and now the importance of careful convalescence is being urged. Speaking to the Society of Medical Officers of Health, the incoming President, Dr. T. W. **Naylor Barlow**, expressed the opinion that much ill-health and many of the disabilities in adult life leading to casual labour and poverty are caused by incomplete convalescence from the so-called minor ailments of childhood. While that is undoubtedly true, the effects of insufficient convalescent care after many diseases of later life can be no less crippling. In 1920 the Birmingham Hospital Saturday Fund spent more than 50 per cent. of its total collections on the upkeep of convalescent homes, and in the same year Sir **Napier Burnett**, in a survey of the hospital situation throughout England and Wales, recommended that every encouragement should be given for the establishment of convalescent hospitals in the country, for the dual purpose of pre-hospital and post-hospital care.[1] This movement towards the systematic treatment of convalescence and sub-standard health conditions has received further emphasis by the inauguration of the magnificent Astley Ainslie Institute in Edinburgh, and the opening, this week, of the Catherine Gladstone Home at Mitcham, Surrey, in connexion with the London Hospital. In America the Burke Relief Foundation, which has functioned since 1915, has enabled valuable conclusions to be drawn regarding the necessity of convalescent facilities for balanced advance in public health work.[2]

Thus the convalescent home is ceasing to be regarded as a luxury of the well-to-do, and the establishment of such institutions for the poor is now recognised as an economic factor of national importance. Indirectly, by giving an opportunity to study disease from a viewpoint hitherto rather neglected, the convalescent home will extend the field of the hospital; but, more directly, acute conditions may be aborted, or distressing sequelæ averted, in patients whose disability does not justify their claim to the costly resources of a hospital bed. Among the hospital population an ailing member in the family circle is often a burden that soon becomes intolerable, although the patient is considered to be out of the doctor's hands. In this connexion may be instanced certain subacute heart and kidney cases, where the only treatment called for is rest and respite from the demands of an active life. The instructions to "take it easy" are often impossible of fulfilment in the home, and yet the swollen waiting lists for the hospital wards require immediate dismissal of a case so soon as the danger period is passed, although the patient may be actually still unfit for the exigencies of normal life. This is the gap—between unfitness and a return to normal activity—that the convalescent home is designed to bridge. Apart from the obvious physical advantages to the patient from a more or less prolonged and carefully supervised sojourn in convalescent home, the psychological aspect of this treatment is of the greatest importance. Convalescence should be a period of re-education to the normal standards of self-supporting existence. This point is—often of necessity—frequently overlooked by the hospital physician; but to the patient, whose body and mind have been exhausted in a long struggle with disease, the return to family life may seem at first overwhelming. Attention to an invalid who is not ill enough to be interesting is apt soon to become irksome, and the patient, sensitive to his or her temporary uselessness among wage-earners, may easily give way to despondency and despair, thus making matters worse all round. In the Burke Foundation scheme great importance is placed on re-education, and results amply justified the experiment. The therapy of "help each other," with the hopeful outlook a non-medical atmosphere engenders in the mind of the convalescing patient, was found to be more valuable in promoting a speedy recovery than much elaborate medication. Each case, of course, must be treated on its own merits, and the right selection of patients for convalescent treatment is essential.

There is no need for the convalescent home to be an elaborate and costly institution, the simpler and the more self-supporting it is the more will its purpose be furthered. The provision of such centres would greatly lighten the work of the hospitals and reduce expenses considerably, while meeting a very real and urgent need among the people. Until—if ever—the nation is adequately housed, the benefits of hospital treatment are too often annulled by the immediately subsequent conditions of home life in a hovel. We commend to testators and donors a fruitful outlet for wealth.

THE INTIMATE MECHANISM OF INFECTION.

In spite of the voluminous literature upon the subject of immunity, the intimate mechanism by which the body resists and overcomes organismal invasion is still very far from being understood. The work of the last 20 years, and the arguments of the humoral and cellular schools, have given us an enormous mass of facts and experimental data upon the interaction of bacteria and their products with the body fluids and cells under various conditions. Search has been made for a simple mechanism which will explain all cases, and this is probably a search for something which is non-existent. Organisms differ so enormously in their physical properties and biological activities that immunity in all likelihood exists in many types. The main result of the enormous mass of work which has been expended upon this subject in the humoral field has been to elucidate a train of test-tube reactions, such as the precipitin, agglutination and complement-fraction tests. These have become of great importance not only in diagnosis but in medico-legal work and even in the field of commerce; and yet they are only by-products of the main line of research, and as far as can be seen play no very important part in the bodily mechanism of resistance, defence, and recovery, although they may be coincident phenomena. In the cellular field **Metchnikoff's** classical studies overtop everything, and here indeed there has been a good deal of enlightenment, although the phagocytic doctrine is far from being sufficient to explain every case. In these circumstances it is only natural to ask if other forms of aggression, on the part of the organisms, may not exist side by side with corresponding means of defence on the part of the body, and to inquire if in our extant studies we have not largely missed the mechanism involved.

---

[1] The Lancet, 1920, ii., 1226.

[2] Ibid., Sept. 1st, 1923.

This aspect of the problem is the theme for a recent essay by Dr. **ARTHUR EASTWOOD**, published by the Ministry of Health.[1] In reviewing the existing work he is considerably attracted by the old hypothesis of **BAIL**, that in its growth in the body the bacterium produces a special form of toxin, named by its discoverer "aggressin," which enables it to establish itself and to successfully overcome the forces of resistance. The fundamental experiment of **BAIL** consisted in inoculating a culture of an organism into one of the serous cavities of an animal. After a certain incubation period the resulting effusion was withdrawn and freed from organisms; it was then found that the sterile fluid, although in itself relatively non-toxic, had the power of so raising the potency of a culture that a dose of the latter, ordinarily non-fatal, became easily lethal when mixed with this fluid. Further, the "aggressin," as the active principle of the fluid was called, had the capacity of exciting immunity when injected alone; so that from the point of view of these experiments the problem of immunity became one of reaction between aggression and antibody called forth in response to its presence. The objection to **BAIL**'s theory has always been that the highly complex material which contained his aggressin contained also both endo- and exo-toxins from the organisms injected, as well as protein degradation products, and that the results, far from being due to a single substance, were due to a very varied mixture of substances. The aggression theory has lain on the shelf, little disturbed, for a number of years now. Interest has recently been revived by an account of somewhat similarly acting bodies which **ZINSSER** has obtained in vitro. Dr. **EASTWOOD** thoroughly surveys the work in this field, and although he has an evident liking for the hypothesis we have discussed, he concludes that its truth has not been definitely proven. He gives us a most interesting discourse upon virulence, but at the end we are still left wondering what it is that makes an organism pathogenic.

◆

THE SPECIAL COURT OF INQUIRY.

LAST week, as every one knows, the Panel Conference took the bold and straightforward course of accepting a Special Court of Inquiry to determine the amount of the capitation fee to be paid next year. The decision to do so, although it was not reached until after a critical debate, was in the end unanimous. During debate it was pointed out with justice that a voluntary association cannot keep up interminably a fierce struggle, that a Court of Inquiry would give unlimited opportunity for mud throwing at the panel service, and that an award of less than the Minister of Health's offer would spell irretrievable disaster. But the argument as put from the chair appealed irresistibly to the Conference: If your case is really very sound, go for the Court of Inquiry and have it settled properly. The fact was recognised by this resolution that no organisation can afford to act illogically. What, indeed, is the purpose of organisation except to stand out for just rights? Criticism of the panel service by friendly society officials must be met somewhere, within or without Parliament, and the campaign of propaganda (it has been called "impropaganda") has already been set going by circulars to insured persons. A Special Court of Inquiry is indeed in another form the arbitration which was repeatedly asked for by the panel executive and refused by the Minister—or so it must be regarded by the thinking public whose sympathy it is essential for the doctors to retain. This is the simple train of thought which led to the decision, and it is unnecessary for us to report further the stages by which it was reached.

The political situation will not materially affect the Court of Inquiry. As our Parliamentary correspondent tells us, the Minister of Health had already issued invitations to possible members of the court before Parliament was prorogued. The court is to be composed of three or five persons of the type of those who arbitrated in 1920, and there is no reason to doubt their impartiality. The actual terms of reference have not yet been drafted, but the court will be asked what would be the proper capitation fee to be paid to insurance practitioners for their services as from Jan. 1st next on the basis of the existing terms of service, with the modifications resulting from the negotiations of this summer. The Minister has let it be known that it will be open to all parties to appear before the court, and that the approved societies, "who represent to a very large extent the insured population," will have the fullest rights to state their views. The court, however, will only be competent to consider such evidence as will assist it to decide what the service as above defined is in fact worth; wider questions of policy will remain to be dealt with by the Royal Commission. It will be therefore for the Commission and not for the Court of Inquiry to consider such questions as those raised by the National Medical Union in a circular, of which a copy has been sent to us, entitled "The National Health Insurance Act from the point of view of the Non-Panel Doctor." The Union is of opinion that, as long as human nature remains what it is, contract practice of any kind will be thoroughly unsafe and bad, for the reason that it inevitably means a maximum of profit for a minimum of work. The Act has, it is stated, actually increased the poverty of those who through frequent illness are reduced to a chronic state of distress, without relieving their ill-health. Anyhow, the loss of independence and self-respect, alleged to be induced by the Act among both insured people and the doctors who attend them, more than counterbalances the relief afforded. Furthermore, the Act provides men of inferior ability and qualifications with a comparatively quick method of obtaining a livelihood, and until the medical benefit portion of the Act is remodelled or erased, the quality of medical practice will continue to deteriorate and the health of the people will suffer. This is the considered opinion of a responsible group of general practitioners, and it would surely be impossible even for approved society officials to state a case with more vigour. But the Union is not against the principle of national insurance as such, and believes that a solution may be found in a system of unfettered private practice under a contributory scheme by which the insurance pool would be used for payment of medical bills. The work of the Court of Inquiry will be done when the total amount of money to be distributed among the doctors engaged in insurance practice has been determined. It will remain as heretofore largely for the doctors themselves to determine the method of distributing the pool. Those, however, who are best qualified to judge see little evidence during the last ten years in support of the assumption that contract medical practice has deteriorated, while vital statistics refute the suggestion that the health of the people during that period has suffered.

◆

MEDICINE AND LITERATURE.

AT the Royal College of Physicians of London on Nov. 20th Mr. **EDMUND GOSSE**, LL.D., delivered the first David Lloyd Roberts Lecture, taking as his subject Personal Relations Between Medicine and Literature. Sir **HUMPHRY ROLLESTON**, who presided, referred to the occasion as unique not only because that was the first lecture under the David Lloyd Roberts Bequest, but also because the College had never before had the honour of sharing a lecture in common with the Medical Society of London and the Royal Society of Medicine. He recalled the circumstances of the founding of the lectureship, and claimed credit for the choice of the first lecturer.

---

[1] Reports on Public Health and Medical Subjects, No. 22. Bacteriological Studies: I. "Factors Determining Bacterial Virulence." H.M. Stationery Office.

Mr. Gosse described himself as not personally acquainted with Dr. Lloyd Roberts, and therefore as dependent for his impressions of the latter on the reports of others, chief among whom were Dr. W. E. Fothergill and Dr. Herbert Spencer. He understood that Dr. Lloyd Roberts, although reticent as to his exact age, was at least 85 when he died in 1920. He was a self-made man, who, like Keats and Ibsen, received his first impressions among the gallipots of an apothecary; he retained throughout his life a certain roughness of temper. Mr. Gosse went on to say that they were met not because Dr. Roberts was a great gynæcologist, but because he frequented bookshops as a collector in the best sense of the word. He himself was anxious to approach his subject in the spirit which Dr. Roberts would have wished; in his own first youth he had had the ambition to be a surgeon, and although constitutionally unfitted for the career had proceeded a little way in it. Passing to what history offered in testimony of the relation between the professions of medicine and literature, Mr. Gosse said he wished to separate the two groups, usually joined, of men who had given literary form to their medical writings, and of men who had written prose and poetry apart from their profession. The greatest of ancient physicians were conscious of literary form; Ambroise Paré had noticed that Hippocrates took care to write simply and clearly, apparently that women and girls should be able to understand his meaning. Phœbus Apollo, destroyer and healer, was god of medicine as well as president of Parnassus. There was no need to recall the fact that the author of the "Religio Medici" was a man of letters. Salerno, celebrated for its salubrity of climate, had formed the nucleus of medical education in the early Middle Ages. Little though we knew of this school, it was a shining lamp amid the darkness of the ninth century; when all other education was crushed into ecclesiastical form, the school of Salerno held to sanity amid priest-ridden superstition and ignorance. The professors of Salerno wrote in clear language, using no inflated jargon of the other schools; he liked to think that something of the Greek spirit remained with them—that they cared for the humanities as well as for humanity.

Tracing the apparent influence of the Salernians on later medical literature, Mr. Gosse expressed himself as unable in the short time at his disposal to deal with Rabelais and Montaigne, but hoped that some successor would expatiate in those directions. Paré first dared to address the ordinary reader in the latter's own language, although his fellow physicians tried to suppress his works on the ground that their terms were intelligible outside the profession. Early in the seventeenth century the writings of Paré were translated into English; Sir Thomas Browne then began to compose the "Religio Medici"—the earliest work in which the harmony between the physician and the man of letters was apparent. In 1659 Thomas Spratt, afterwards Bishop of Rochester, published a poem which nominally dealt with the plague at Athens described by Thucydides, but really referred to the outbreak which had lately occurred at Naples. Such an extended work entirely on medical themes was not repeated until Garth published his poem 40 years later. Continuing, Mr. Gosse referred to Sir Thomas Browne, to Locke, the friend of Sydenham, and to Sir Richard Blackmore, whom he described as a reputable physician misrepresented by the hostility of Dryden. Blackmore, who became a Fellow of the Royal College of Physicians in 1657, produced two long and vapid poems, Prince Arthur and King Arthur, which were widely read and savagely attacked, the writer also being asked why he did not treat of some useful medical subject. After that time the question was no more raised in England; the barrier between imaginative literature and medical science was finally broken down when Sir Samuel Garth's long mock-heroic poem, The Dispensary, dealing with the quarrel between physicians and apothecaries over the furnishing of free drugs to the poor of London, appeared in 1699. Garth's poetry was only half-poetry, and his science only half-science, but he drew the subjects together as they had never been drawn before. Before Garth died the connexion between medicine and literature had become not the exception but the rule; a warm comradeship was established between doctors and authors in the greatly improved civilisation of the reign of Anne. Pre-eminent among the lettered physicians of those days was Dr. John Arbuthnot, who took up the mantle of Garth, and was always most at home in the company of authors. Pope and Swift were invalids, neurotic to excess, made difficult of access by intense nervous irritability; the cheerful humour of Arbuthnot was their constant bromide. Also among his friends were Gay, Parnell, Atterbury, Steele, and Congreve. An Aberdonian, Arbuthnot gained slow recognition in London, until Prince George was taken suddenly ill at Epsom when Arbuthnot happened to be present—an illustration, remarked Dr. Gosse, of the fact that talent and industry were insufficient for success without the sovereign element of good luck. Arbuthnot became a Fellow of the College in 1723; he remained a planet in the constellation of wits for a quarter of a century. He was still remembered for the irony of his "History of John Bull"; of his medical writings the most famous dealt with the nature of "animates"—what would now be spoken of as vitamins. Of medical men who made names in literature during the eighteenth century, Oliver Goldsmith and others never received recognition from the College; but Mark Akenside, poet and anatomist, enjoyed every distinction the College had to bestow. Coming to the present day, Mr. Gosse recalled the fact that the Poet Laureate was a medical man, and expressed his belief that if Dr. Roberts had chosen to perpetuate his subject in sculpture, instead of by oratory, he would have selected a statue of Arbuthnot, together with busts of Pope, Swift, Steele, and Gay, to crown the monument.

Annotations.

"Ne quid nimis."

DENTAL BOARD OF THE UNITED KINGDOM.

The autumn session of the Board was opened on Nov. 13th at 44, Hallam-street, W., when the chairman, Mr. F. Dyke Acland, delivered an address. Only within the last few months, he said, had the Board been able to begin to deal with the many important duties which would normally devolve upon them, the first 18 months of their time having been occupied with the machinery of registration. The day seemed to draw nearer when by the process of ordered evolution the Board might, much to the regret of its other members, lose the representatives from Southern Ireland. The passing of the Dentists Act of 1923, which became law in July, necessitated an amendment of the Regulations; an opportunity would be taken to amend the table of fees, and to obtain authority for their remission in certain cases, in order to carry out the wishes of the Board and prevent hardship for those who would have qualified prior to the passing of the Dentists Act, 1921, had it not been for the war.

It was, Mr. Acland said, of the utmost importance, if sufficient dentists were to be obtained to meet the requirements of the population in future, that the number of students should be increased. The Board had already taken steps to this end; large sums of money had been expended in helping those who found that the Government grants were not sufficient to enable them to complete the curriculum; a beginning had also been made in the granting of bursaries to persons who, for want of means, would have been unable to enter upon the profession of their choice. It would be necessary to spread these over as large a number of students as possible, and, though the grants hitherto had been on a liberal scale, the Board might not be able to continue them so freely, and experience alone would show what could be done in this direction. In connexion with propaganda for instructing the public in the great importance of having their teeth properly attended to at regular intervals, and of taking care to prevent decay, from the point of view of the health of the nation this matter required earnest consideration; he felt sure it would be to the public advantage if the Board could take steps to carry out some of the suggestions made in the Report of the Departmental Committee. Applications had been invited from schools for assistance to enable them to deal with a large number of students when these have been obtained, and to give them the best facilities for instruction. Arrangements had been made for an extension of the lectures on the higher scientific branches of dentistry given in the early part of this year. It was hoped that full advantage would be taken of them, and that, when published in pamphlet form as they would be, those who desired to study at their leisure the valuable information provided would have an opportunity of adding the work to their professional libraries at small expense. Courses of instruction had also been provided for persons who obtained registration in virtue of long years of practice, or of having passed the prescribed examination. Great assistance in this direction had been rendered by some of the dental schools, which was much appreciated, and the Board had arranged for experimental courses to be held at three or four centres where such schools are not available. The indications were that the applications to attend would be numerous. The Board were much gratified by the help promised in the direction of research both by the Medical Research Council and the Department of Scientific and Industrial Research. It was hoped to make considerable grants, extending over a series of years.

The Board, Mr. Acland continued, had to consider an arrangement arrived at between the British Dental Association and the Parliamentary Committee of the Coöperative Congress in regard to the association of dentists with coöperative societies. This question, which at one time threatened to prove very difficult, had through the good offices of the officials of both of these bodies, been solved so far as they are concerned. The question, however, has been raised as to whether the arrangement come to constituted the carrying on of the business of dentistry by the societies, and this the Board would have to consider. At present there appeared to be some difficulty in regard to panel practice, and, though the matter was not one which directly concerned the Board, it might be necessary to take it into consideration. With regard to disciplinary cases, there had been a noticeable improvement in regard to advertisements, signs, and other matters which, from a professional point of view, were not desirable. The time had now come when all dentists might be expected to know the views of the Board on the subject, which in the main might be summed up by saying that signs, other than those necessary to enable patients to find the premises they sought and announcements in the press, which contained the word "dentist," or anything relating to dentistry, might be considered to be advertisements; and before long it might be necessary for the Board, instead of warning practitioners, to summon them to appear in answer to a charge which, if found proved, might have very serious consequences for those concerned. The Board had successfully undertaken a considerable number of prosecutions of persons illegally practising dentistry; in view of the fact that the Act has only been passed recently, merely nominal penalties had been asked for. In this matter, again, the time was coming when the Board would have to ask that offenders might be severely dealt with. Magistrates had sometimes said that offenders had received no warning from the Board, but it must be borne in mind that, if it were customary, before taking proceedings, to warn, there were some persons who possibly would carry on to the last possible moment in expectation of this, and some persons, if warned in one district, would promptly move to another. It must be clearly understood that for an unregistered person to see a patient, whether in connexion with the fitting of artificial teeth or in any other way, was a breach of the law; and it was the intention of the Board to see that the provisions of the Dentists Act, 1921, were strictly carried out.

RAPPROCHEMENT WITH VETERINARY MEDICINE.

An excellent example of the light which may be thrown upon the problems of human physiology and pathology by research undertaken from a purely veterinarian standpoint is afforded by investigations recently made by Dr. Theobald Smith and Ralph B. Little, V.M.D.,[1] at the Department of Animal Pathology of the Rockefeller Institute for Medical Research, into the significance of colostrum to the new-born calf. The investigation originated in an attempt to throw some light upon the high mortality of calves in the first week of life; this high mortality due to "scours," inflammation of the umbilical stump, and acute arthritis is the bane of owners of prize herds to whom it means the annual loss of many valuable animals. The infective nature of the fatal conditions has long been recognised and attempts have been made to combat them by isolating the calf immediately after birth and feeding upon sterilised or "clean" raw milk. The proved futility of these measures seems to have afforded the stimulus for the work of Smith and Little. They took two groups of calves; the animals constituting the first group were removed from their dams as soon as born and before they had had the opportunity to suckle; they were washed and dried with all possible aseptic precautions, the umbilical cord was snipped off and treated with antiseptics, and the calves then wrapped in blankets and transferred in a specially protected motor-lorry to the experimental units of the Department, a distance of about one and a half miles. The animals of the second group were left with their dams 24 hours, during which time it was ascertained that they suckled freely. They also were then removed to the Department units. At the units the calves of both groups were subjected to exactly the same treatment and given the same diet of fresh raw milk. Attention was directed to the condition of the calves during the first week of life, this, as pointed out above, being the danger period. During this time the fates of the animals constituting the two groups were strikingly different. Of the ten calves which had taken freely of colostrum, all remained alive and healthy; of the 12 which had received none only three survived this first week. In the nine animals which succumbed death was in every instance due to a blood infection by *B. coli*, this organism being readily recoverable from the spleen, liver, and kidneys, and in those which had developed arthritis from the joints also.

Although they do not definitely say so, the impression of the authors appears to be that the infecting strain of *B. coli* was not necessarily pathogenic. It is known that both in man and the lower animals *B. coli* appears in the bowel very shortly after birth; the conclusion of Smith and Little is that in the absence of the colostrum this organism, instead of remaining a harmless saprophyte in the gut, gains ingress to the blood-stream and gives rise to a systemic infection. In the human field the above piece of research is complementary to recent observations on the constitution and function of the colostrum. Thus Lewis and Wells[2] have shown that the blood of babies at birth contains little globulin and practically no euglobulin; colostrum they found to be rich in both these bodies. Moreover, they clearly demonstrated that whereas the proportion of these bodies rose rapidly in the blood of babies who had received colostrum, in those who had not the normal level was not attained for several weeks. It has long been recognised that antibodies of all sorts are associated with the globulin fraction of the serum, and the above authors suggested that the colostrum is the vehicle of conveyance of the maternal antibodies to the serum of the offspring. The observations of Smith and Little throw light upon several other points in human pathology which cannot be touched upon here; but alone in giving practically conclusive proof of the validity of the tentative suggestion of Lewis and Wells they demonstrate the value of the comparative outlook in medicine.

THE ÆTIOLOGY OF URINARY LITHIASIS.

Linwood D. Keyser[1] has carried out a series of experiments on rabbits to test some of the various theories that have from time to time been put forward to account for the formation of calculi in the urinary tract. He has produced evidence against the view that a diet rich in calcium is a predisposing factor in stone formation, by feeding rabbits with massive doses of calcium oxalate, chloride, lactate, and phosphate. Healthy rabbits were used and also some in which a mild degree of toxic nephritis had previously been produced by the administration of small doses of oxalic acid, cantharides, chloroform, and mercuric chloride. In no case was there any demonstrable increase in the crystalline content of the urine nor was there any concrement formation. Similarly, the presence of an organic foreign body in the pelvis of the kidney as a predisposing cause was disproved by placing small pieces of fascia and muscle under sterile conditions into that region. In only one case, and that in which bacterial infection had taken place, was there any deposit round the foreign body. One substance was, however, found to produce stones when given orally—namely, oxamide (the diamide of oxalic acid $\begin{matrix}\mathrm{CONH_2}\\ | \\ \mathrm{CONH_2}\end{matrix}$). When rabbits were fed on this compound, 75 per cent. revealed a deposit of gravel and 50 per cent. stone formation, although cultures of the organs were repeatedly sterile. The amount of oxamide found in the urinary tract after death did not appear to be influenced by the reaction of the urine, variations in dosage, and duration of the feeding within wide limits. The oxamide in the urine consisted of pigmented crystals in the form of crosses, simple and rough, squares and spheres, the latter tending to fuse to form small concrements and stones. Crystals of oxamide produced synthetically by treating oxalic ester with ammonia were found to have the form of translucent, colourless, fissured rhomboids, some with roughened and split ends. If these were dissolved in urine, and re-precipitated by heating, the process being repeated several times, crystals were produced exactly similar to those obtained from the urine of oxamide-fed rabbits, and if the latter crystals were dissolved and passed through heated charcoal, the pigment was extracted, and forms resulted exactly similar to those produced synthetically. Thus it would appear that "the urinary colloids act on the oxamide crystals so as to transform them into fusing forms." It is probable that the colloids in the urine normally keep the water-insoluble crystals (urates, oxalates, &c.) in solution, but if any foreign crystalloid is present, such as oxamide, there is no mechanism to keep its crystals separate as morphological units, nor to keep it in solution, and therefore it is precipitated by the normal colloid so as to produce fusion and concrement formation. Further, the presence of an abnormal colloid or any interference with the normal colloids in the urine may cause the normal crystalloids to be precipitated. Although the most likely source of an abnormal colloid seems from clinical and experimental data to be inflammatory exudates, the fact that in pyelitis and nephritis stones are uncommon proves that not every inflammatory exudate produces stone, nor does every abnormal colloid, and therefore it is possible that stone-forming colloid and colloid-forming bacteria are specific. The experiments quoted above also show that an abnormal crystalloid may be precipitated without the presence of infection. In a further series of oxamide-fed rabbits it was demonstrated that roughening of the renal pelvis resulted in a greater deposit of oxamide on that side, and that slight constriction of the ureter brought about stone formation in every case, whereas, in the absence of constriction, stones were formed in only 50 per cent. Where pieces of fascia or muscle were placed in the pelvis, stone formation was consistently noted round such a nucleus. Hence, it was concluded that "duplication of surfaces, diverticula, stasis, hydronephrosis, and nuclei, while not the cause of stone, greatly enhance the chances of retention of fusing crystals when these are present, and in this manner foster the formation of larger stones." Clinically, therefore, stones may be caused by the pouring out of abnormal colloids from an infected kidney, these colloids causing precipitation of crystalloids and their fusion. This conception explains why removal of the infected kidney is seldom attended by a recurrence of stones, and why recurrence in an infected bladder is so common. It also lends support to the views held by many authors that any focus of infection, or any lowering of the resistance in the individual may be a predisposing factor in the formation of calculi.

HYDROGEN CYANIDE AS A DISINFESTOR OF SHIPS.

Dr. P. G. Stock's paper, read before the Section of Epidemiology of the Royal Society of Medicine on Nov. 23rd, dealing with the use of hydrogen cyanide and allied substances as disinfestors, has an important bearing on international preventive medicine. In the account of two recent cases of fatal poisoning by hydrocyanic gas occurring during the deratisation of a liner at Southampton, Dr. Seager Thomas[1] indicated the early publication of a report by the Ministry of Health dealing with this method of fumigation. Full investigation into the risks as balanced by the advantages of hydrogen cyanide as a fumigant has not yet been completed, but the Ministry have now issued a preliminary report,[2] embodying the knowledge and experience so far acquired concerning the gas. In the first place it is pointed out that hydrogen cyanide is not a disinfectant, and is not used for ordinary purposes of disinfection of houses or clothes—e.g., after infectious fevers. It is, however, a powerful agent for the destruction of animal life, and of insect pests generally. The fumigant hitherto favoured in this country has been sulphur dioxide, but the advantages claimed for the use of hydrogen cyanide, for the destruction of vermin on board ship, are, apart from the time occupied in the process, the absence of danger from fire and of damage to metal work, paint, fittings, and cargo; it is also supposed to be less expensive in practice. The outstanding disadvantage of its employment is that every stage of the process is accompanied by danger to the lives of all persons engaged on the work of fumigation. The report, however, shows that this danger can be reduced to a minimum provided adequate precautions are taken, and strictly maintained throughout the whole process. Further, the fatal accidents which have occurred in this and other countries are held to be due mainly to lack of precaution or to carelessness of the operators.

The steps employed in the fumigation of a ship can be divided into three stages: (1) The ship is inspected and the details of the fumigation planned. All openings are then closed, and the generating plant placed in position. (2) The plant is charged and the gas generated, when the vessel is left under fumigation. (3) The ship is opened up and allowed to ventilate, tests being made to determine when she is free from gas. To prevent accidents two precautions are necessary: (*a*) The employment of only a trained personnel, and (*b*) the use of effective respirators. Should an accident occur, it appears that artificial respiration employed as soon as possible and without waiting for other means of assistance affords the best prospect of success The methods employed in generating the gas were detailed in these columns some months ago.[3] As hydrogen cyanide gives no warning symptoms in sublethal concentrations, attempts have been made to combine it with some lacrymatory substance. Such a mixture, known as "Cyklon," has been used in Holland, but it is still on trial. Liquid hydrogen cyanide contained in steel cylinders has been employed, but, after a rise of atmospheric pressure, the cylinders have been known to burst. The dangers of such an accident are obvious.

---

[1] THE LANCET, 1923, i., 1210.

[2] Preliminary Report on the Use of Hydrogen Cyanide for Fumigation Purposes. By Dr. P. G. Stock and Mr. G. W. Monier Williams, Ph.D. London: H.M. Stationery Office. 1923. 2*s.* 6*d.*

In his summary of the report Sir George Newman states: "There is no doubt either as to the efficiency of fumigation by hydrogen cyanide for the destruction of rats and vermin, or as to its danger. It must, I am afraid, be considered a hazardous occupation, and the question arises whether the application of this method of disinfection should be specially restricted by licence." The enormous wastage to health and to merchandise alike caused by vermin renders imperative the most stringent measures for their destruction. Hydrogen cyanide is efficacious, but it is admittedly dangerous. Perhaps the solution of the problem lies along the lines of improved ship construction which would render rat harbourage impossible and destruction unnecessary.

THE OUTBREAK OF DYSENTERY IN DEVONSHIRE IN 1922.

A REPORT[4] has been issued by the Ministry of Health upon the outbreak of gastro-enteritis which occurred at Lynton, in Devonshire, during October, 1922. It appears that the first cases were noted as early as June of that year, after which cases of what are now presumed to have been mild bacillary dysentery cropped up at regular intervals till the date of the main outbreak. Lynton is situated 600 feet above sea-level, occupies an area of some 7000 acres, and has a population of 1770. The outbreak was confined solely to the town. Inquiry directed to the sanitary condition of the district failed to show any evidence that the water-supply or the methods of sewage disposal could be held responsible for the outbreak. In the course of the investigation the milk from a single farm situated two miles from Lynton came under suspicion, for, with two exceptions, every sufferer in the outbreak had consumed milk obtained from this farm, and even as regards the two excepted cases it could not be positively stated that they had not partaken of this milk. The dairy-farmer proved to be an ex-officer who had suffered from an attack of dysentery in the East in December, 1917, and it appeared that he had taken an active part in the dairying of the milk, and assisted in its distribution to his customers. The discovery of this interesting circumstance led to the despatch of Mr. Bruce White to make bacteriological investigations on the spot. The actual discovery of Flexner's dysentery bacillus was made in the mucoid stools of a child aged 6 years, the son of the foreman residing on the farm which was under suspicion. From the next case that occurred a culture of Shiga's bacillus was obtained. The blood of the owner of the farm was found to agglutinate Flexner's bacillus in high dilution, while from the stools of the foreman Shiga's bacillus was obtained. After this 18 cases of bacillary dysentery were noted in 11 households, of which 13 occurred in children. The chief interest in this small outbreak lies in the completeness with which it has been possible to coördinate the epidemiological and bacteriological findings. These leave little doubt that the infection was spread through the agency of milk, and that the source of infection was an active carrier of dysentery bacilli, who proved to be the farm foreman. The main points of scientific note are the proof that milk may form a medium for the dispersal of dysentery bacilli, and that a carrier of the disease may remain infective for a period of five years.

OCULAR INJURIES.

AN article in the September number of the *American Journal of Ophthalmology* records in outline 28 cases of ocular injury, direct or indirect, with sketches showing the fundus conditions. In some cases diagrams are appended to indicate the exact points at which the injuries were inflicted. The result is to confirm, in the main, the "laws" formulated by Félix Lagrange, the most remarkable of which are: 1. The commotion of air by the explosion of a shell at a distance may injure the eye so severely that the inner membranes are lacerated. These lesions are located generally at the posterior pole of the eye, and are sometimes very extensive. When the eye is shaken the uveal membrane is the first to give way, so that choroidal ruptures are common from this cause. 2. When the missile passes above the orbit it produces fracture of the orbital vault; the sensory and motor nerves of the orbit may be involved, but the eyeball itself is uninjured. 3. When the missile travels through the face below the eyeball, without fracturing the orbit, it produces lesions by concussion involving the eye at the level of the macula lutea. It is the most common cause of impairment or loss of central visual acuity. The lesions are the result of the concussion transmitted to the contents of the orbit by the pterygo-maxillary fossa and spheno-maxillary fissure. Among the cases of which diagrams are given are included hæmorrhages, hole at the macula, ruptured choroid, and central retino-choroiditis, sometimes slight, at others very extensive.

THE "BLACK JACK" SIGNATURE BOOKS.

AN interesting addition has just been made to the library of the Royal College of Surgeons in the shape of three volumes of Signature Books from the old "Black Jack" public house, which stood, before a process of demolition began in about the year 1902, near the old King's College Hospital. The donor, Dr. Albert E. Jones, of Crickhowell, purchased these three volumes in the "Old Curiosity Shop," which stands nearly opposite the site of the Black Jack. A fourth volume has not so far been traced. The signatures are those of young medical men, who had just "passed the College," in the phrase of a past generation, or, in other words, had just qualified as Members of the Royal College of Surgeons of England. Naturally enough, considering where and on what occasion they were written—though the word "naturally" is a sad comment on the times—the handwritings often betray traces of alcoholic exhilaration, and in many cases sprawl exceedingly. Several newly-fledged Members of the College have taken a whole page to themselves; others indulge in witticisms at the expense of fellow-signatories. The earliest autograph in Volume I. is that of Thomas Webb Fryer, of Bristol, who passed the College on Feb. 4th, 1854, and practised for many years at Grampound in Cornwall. The last signature is in April, 1892, and is that of a gentleman still in practice in London. The later autographs, be it said, are decorous enough, and are in respectable contrast to the smudged and vinous ones of the fifties and sixties. The Bob Sawyer tradition may be said to have begun to pass into oblivion while the Signature Books were still in existence. As early as 1871 we find it referred to as a thing of the past by Dr. William Fairlie Clarke, M.A. Oxon., F.R.C.S., whose name is not in these curious old "matriculas." "Time was—and that not very long ago,—" he wrote, "when the name of a medical student was a synonym for coarseness and vulgarity, if not for profanity and licentiousness. But happily that time has passed away, we may hope for ever." It must have been a coarse and profane fellow who drew the caricature of the President of the Royal College of Surgeons, Edward Stanley, in 1857, but as a matter of fact he thus left on record, in Vol. I. of these quaint old books, the only portrait of Stanley, apart from the bust by Lough, which is now known to us. In the recent Gardner sale water-colours by J. P. Emslie and J. I. Wilson, portraying the ancient interior and mean-looking exterior of the "Old Black Jack," fetched a high price.

[4] Report on an Outbreak of Dysentery in the Urban District of Lynton, Devon. By George C. Hancock, C.B.E., and P. Bruce White, B.Sc. Reports on Public Health and Medical Subjects, No. 20. H.M. Stationery Office. 4*d*.

THE ÆTIOLOGY OF WARTS AND PAPILLOMATA.

At the University Hospital for Diseases of the Nose, Throat, and Ears in Vienna, Dr. E. V. Ullmann has recently been carrying out some interesting investigations into the ætiology of warts and papillomata. According to his report, which is published in *Acta Oto-Laryngologica* (Vol. V., Fasc. 3, 1923), the starting-point of his investigations was a case of papilloma of the larynx in a 6-year-old boy. Early in June, 1921, some of this growth was removed, and after it had been washed in saline solution it was crushed in a mortar into an opaque milky fluid which was inoculated into abrasions in Dr. Ullmann's left arm, and also into abrasions in the abdominal wall and hard palate of two dogs. The entrance to the vagina of one of these dogs was also inoculated, the vagina being sewn up to prevent the dog licking it. By the middle of September small flat warts, resembling the initial stage of rapidly growing herpes tonsurans, had developed on Dr. Ullmann's arm. They grew quickly, developing the appearance of a pedunculated many-branched papilloma. At this stage the site of inoculation in the vagina of the dog showed several small warts of a reddish colour. After five weeks' further growth they presented the appearance of a pedunculated papilloma. At the time the papilloma was removed from the larynx of the child, his upper lip was slightly injured, and three and a half months later several small flat warts developed on the upper lip, spreading thence over the whole of the face. It was noteworthy that, while the secondary growths on Dr. Ullmann's arm and in the vagina of the dog were pedunculated, those on the child's face were flat warts. Dr. Ullmann removed a small piece of the papilloma from his upper arm on Dec. 3rd, 1921, and inoculated the upper arm of a colleague. Seven days later the reaction had passed off, but on Jan. 8th six small groups of nodules appeared at the site of inoculation, growing very rapidly and extending beyond the inoculated area. After six weeks the growth of these tumours was so luxuriant that they had to be cut away. This experiment showed that the passage of the virus had considerably decreased its incubation period and favoured its rate of growth, observations suggesting that the laryngeal papilloma is an infectious inflammatory disease. Dr. Ullmann has also passed an extract of a papilloma through a bacterial filter, and has succeeded in cultivating warts on his skin after rubbing the filtrate into abrasions. These and various other investigations have led him to think that the laryngeal papilloma is the result of an inflammatory reaction caused by a filter-passing virus. If his findings are confirmed, the treatment of laryngeal papilloma and allied diseases will have been put on a more rational footing than heretofore. It is noteworthy in this connexion that warts on the hands are particularly common in children suffering from laryngeal papilloma.

THE PROPHYLAXIS OF CONGENITAL SYPHILIS.

Prof. Almkvist, of the Karolinska Institute in Stockholm, has lately published statistics[1] with regard to congenital syphilis, which give a clear lead as to the prevention of this disease. He has classified his material according as: (1) Syphilitic mothers were not given specific treatment before confinement, (2) were given it before but not during pregnancy, (3) were given it only during pregnancy, or (4) were given it both before and during pregnancy. Of the 28 women in the first class, as many as 27 gave birth to infants who, sooner or later, showed signs of syphilis. Of the 26 women in the third class, there was not one whose infant showed signs of congenital syphilis. In the remaining classes there were too few persons for a statistical analysis to be of importance, but the upshot of a study of a total of 67 cases in which the mother or infant, or both, showed signs of syphilis was unmistakably obvious. The campaign against congenital syphilis should be primarily prophylactic, for to start treatment after the birth of a syphilitic infant is to miss the best opportunity. So far Prof. Almkvist will assuredly find every authority in agreement with him. But when he discusses the course to pursue when a child is born to a syphilitic mother, given skilled specific treatment throughout pregnancy, he is on more debatable ground. According to some authorities it should be assumed that the new-born infant may not have escaped infection; it should be "given the benefit of the doubt" and treated as if congenital syphilis had been found. Prof. Almkvist condemns this course, comparing it with that of the physician who prescribes specific treatment for an adult who has been exposed to infection, but has shown neither clinical nor serological signs of syphilis. Even when a syphilitic mother has not been given specific treatment, Prof. Almkvist prefers to withhold specific treatment for her infant till signs of syphilis have appeared. To give specific treatment in such a case is, he argues, unscientific. Till his advice is followed, little can be learnt as to the period in the life of an infant with congenital syphilis when Wassermann's reaction becomes positive. For lack of such knowledge we do not yet know for how long an infant must be kept under clinical and serological observation before it can be stated with certainty that the infant has escaped congenital syphilis. Prof. Almkvist abides by his principle even in the case of the mother who gives birth to a syphilitic infant without showing signs of syphilis in her own body. There were five such cases in his series, and he maintains that these women should be kept under observation and not given specific treatment till it is proved that they are suffering from syphilis. In many of his cases the expectant mothers were ignorant of their infection, and he urges every practitioner confronted with a case of pregnancy to take clinical and serological steps to assure himself that the prospective mother is not syphilitic. While this advice may be sound it is hardly practicable.

THE PATHOLOGY OF TORTICOLLIS.

As long ago as 1830, Stromeyer taught that injury to the sterno-cleido-mastoid muscle during birth gave rise to a hæmatoma in this muscle which subsequently atrophied, the mechanism of torticollis being more or less mechanical. In the "nineties" it was still assumed that this condition began with a mechanical injury to the muscle during birth, but it was thought that the hypothetical hæmatoma developing during labour subsequently became infected, retraction and atrophy of the muscle being due to a fibrous myositis of microbic origin. Recent investigations by Prof. Ali Krogius,[2] of Helsingfors, give support to the view that this condition is a degenerative process comparable with that of Dupuytren's contraction to the pathogenesis of which

---

[2] Finska Läkaresällskapets Handlingar, September–October, 1923.

Prof. Krogius has also contributed much important research. He has carried out microscopic examinations of seven cases of torticollis, the ages of the patients being 8 months and 14, 16, 17, 19, 20, and 24 years respectively. In two cases the torticollis did not begin to develop till the patients had reached the ages of 5 and 15 years respectively, and in two other cases the condition had not been noticed till more than a year after birth. A microscopic examination was also made of a muscle that had undergone ischæmic contracture in connexion with a fracture of the humerus, and also of the rudimentary interosseous muscles of a new-born calf. The degenerative changes already proceeding in these muscles were also found in the sterno-mastoid muscles, but not in the muscle which had undergone ischæmic paralysis and atrophy as a result of a fracture. In three of the adolescent patients these degenerative changes seemed to have come to a certain standstill, the muscles having been converted over an extensive area into firm, fibrous tissue. Only here and there, at the junction of muscle with fibrous tissue, could a soft connective tissue be seen in which a few necrotic fragments of muscle were imprisoned. In all the other cases the process still seemed to be in activity, islands of degenerating muscle being surrounded by actively proliferating connective tissue. This condition was found even in the eight-months old patient, and it was not least marked in the oldest patient. These changes were the same whether the torticollis had begun early or comparatively late in life. Prof. Krogius dismisses as improbable that this formation of connective tissue is merely a secondary phenomenon following destruction of muscle, for he has seen connective tissue proliferation starting in the perimysium at a stage when the muscle cells still completely retained their normal structure. In further support of his views he notes that torticollis may be associated with other deformities of endogenous origin such as hare-lip, congenital absence of muscles, syndactylism, polydactylism, and malformations of the reproductive system. The fact that the anterior portion of the trapezius not infrequently shows the same changes as those found in the sterno-mastoid is also a reason for regarding this condition as a developmental anomaly.

THE dinner in celebration of THE LANCET Centenary is to be held next Thursday, 7.30 P.M. for 8 P.M., at the Victoria Hotel, Northumberland-avenue, Sir Donald MacAlister, President of the General Medical Council, presiding.

Prof. Strandberg, of Copenhagen, is to deliver at the Royal Society of Medicine on Monday, Dec. 3rd, at 5 P.M., a lecture on the treatment of tuberculosis of the nose and throat by means of light baths.

THE next session of the General Medical Council will commence at 2 P.M. on Tuesday, Nov. 27th, when Sir Donald MacAlister, the President, will deliver an address. The Council will continue to sit from day to day until the termination of their business.

RONTGEN SOCIETY.—A general meeting will be held on Tuesday, Dec. 4th, at 8.15 P.M., in the British Institute of Radiology, 32, Welbeck-street, London, W., when a paper on Modern Radiographical Technique will be read by Dr. L. G. Heilbron, of Amsterdam.

In order to commemorate the work of the late Prof. Röntgen, the Council of the Society, at a meeting held on Oct. 25th, agreed that an annual award of £10 (or the equivalent in books or apparatus, at the option of the recipient) shall be presented to that member of the Rontgen Society whose contributions during the session, relating to the science or practice of medical or general radiology are, in the opinion of the Council, of sufficient distinction. In the event of two or more collaborating, the award shall be shared equally between them. The award has reference to papers or demonstrations, read or shown for the first time and before the Society, relating to radiology in all its aspects, and will not be made if, in the opinion of the Council, no contribution of sufficient merit has been forthcoming during the session.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

XLVI.—TREATMENT OF VARICOSE VEINS.

VARICOSE veins is a condition of considerable importance partly on account of its frequency and partly on account of the severe and disabling complications, such as ulceration, thrombosis, and chronic œdema, which are likely to occur in late stages of the disease. In most of these advanced cases curative treatment is impossible and palliative measures afford only a limited degree of relief. Our aim should, therefore, be to treat these cases in the earlier stages, while the patients are young and the trouble localised.

Our knowledge of the cause of varicose veins is not altogether satisfactory. The trouble is common in all classes, affecting both men and women, and in those following both active and sedentary occupations. It is generally agreed that the essential factor is an increase of pressure in the veins occasionally due to some easily recognised obstruction to the flow of blood. Such are pregnancy, pressure by tumours, abnormal communications between arteries and veins, and occasionally thrombosis of the femoral vein or a fracture of the pelvis. In another group varicosity is vaguely attributed to some congenital cause; rarely it is part of a definite angeioma. In another numerous group the trouble is attributed to an habitually overloaded colon, "heart disease," and occupation. It is necessary to consider where and how the obstruction occurs, in order that it may be treated before the valves become incompetent.

I believe, for reasons I have set out in detail elsewhere,[1] that in a considerable proportion of cases, especially where the patient follows an occupation requiring prolonged standing, the real cause of the trouble is an obstruction to the flow of blood near the termination of the internal saphenous vein, where it passes through the saphenous opening, crossing the well-defined cornu of the falciform edge, and leaves the subcutaneous tissues to join the more deeply placed and better supported femoral vein. This is a relationship where some additional factor may easily produce a slight but definite degree of obstruction which, acting over long periods, may produce far-reaching results. This additional factor is, I suggest, increase in the tension of the fascia lata. In the sitting or recumbent positions the fascia lata is relaxed. In the erect position it is tense. If the fascia lata is tense so also must be the falciform edge with its superior and inferior cornua, the latter between the superficial and deep venous trunks. The obstruction thus produced need not be complete; a slight degree of interference acting over a long time will be sufficient to overfill the veins, to cause thickening and dilatation and eventually varicosity. A vicious circle will also be started, for the overfull vein will be heavier, and this will tend to cause a dragging which will aggravate and increase the obstruction when the fascia is tense. The effects of the obstruction need not appear in the upper part of the vein; indeed, one would expect the effect of the pressure to extend downwards beyond the actual obstruction and for the effects to become manifest first in the distant tributaries. There is another possible cause of obstruction at the termination of the internal saphenous vein, where it is joined by the superficial epigastric, the superficial circumflex iliac, and the external pudic veins. Though usually regarded as unimportant, these veins are often surprisingly large, and the flow of blood in them, being from above downwards, is in direct opposition to the flow of blood in the internal saphenous. This cause of obstruction, though probably negligible in the sitting or recumbent position, may be of considerable importance in the erect position when the fascia lata is tense.

---

[1] Guy's Hospital Reports, vol. iii., fourth series, No. 2.

I do not wish to suggest that this is the only cause of varicose veins. I have no doubt that the others mentioned do exist, that they are often of importance, and that they must be taken into account when deciding upon treatment. It is possible, too, that obstruction may sometimes occur in a somewhat similar fashion in the external saphenous vein where it pierces the deep fascia, or in other situations where there are communications between deep and superficial veins.

Operative Treatment.

I have long thought that in the operative treatment of varicose veins it is a wrong principle to excise or obliterate the main trunks of venous return, especially the internal saphenous. The blood has to return from the superficial tissues of the leg somehow, and, if the main trunk is removed a great strain must of necessity be thrown on the smaller vessels, with the result that they become varicose. Even though all the affected veins are excised, only too often fresh veins will be found later to be varicose, sometimes actually beneath the operation scars, while occasionally a large fresh channel will be found to have developed in the course of the excised internal saphenous.

Trendelenburg's operation, in which an inch or two of the internal saphenous is excised immediately below the saphenous opening, is now, I believe, less frequently employed than formerly. It is indicated only where there is definite evidence of a long column of blood, unsupported by valves, extending from the abdomen to the lower part of the leg. In such cases the advantage to be derived by relief from this extensive back pressure may outweigh the disadvantages following on obliteration of the main channel of venous return. Trendelenburg's operation is usually combined with removal of the diseased veins; and it may be taken as a generally accepted fact that if a vein is so seriously affected that operative treatment is required, excision by one of the methods in common use is the only effective way of dealing with it, though this should, if possible, be combined with some measures to remove the cause.

The operative treatment of varicose veins should thus have three objects: (1) To excise those veins or groups of veins which are causing symptoms; (2) to remove the cause of the trouble; and (3) to carry out the above and at the same time preserve the internal saphenous, the main channel for the drainage of the superficial veins of the lower extremity.

Indications for Operative Treatment.

Operative treatment must not be carried out indiscriminately, but only on carefully selected cases, generally young healthy adults. In female patients the pelvic organs must be healthy and the possibility of pregnancy must be remembered. The most suitable cases are those where the trouble is localised to one or more veins or groups of veins. Chronic swelling of the leg, due to solid œdema, with probable blocking of the deep veins, is a contra-indication.

There are several well-known methods of excising the diseased veins. Personally I prefer to dissect out the veins through fairly large incisions rather than to employ methods involving the evulsion of long portions of vein through small incisions. In those cases where it is considered that the varicosity is caused by obstruction at the saphenous opening the plan which I have adopted is the following:—

A New Operation.

The course of the internal saphenous vein is carefully verified. Probably the thickened vein can be felt, but to avoid any uncertainty it should be marked out beforehand. The hip being slightly everted an incision about 4 or 5 inches in length is made just to one side of the vein which is cleared, first to the inner and then to the outer side, so that the deep fascia is exposed for the whole length of the incision. By a little dissection the termination of the vein and the margins of the saphenous opening are defined. The superficial tributaries are then identified and each is divided between two ligatures. The deep aspect of the saphenous vein is now separated from the deep fascia; a director is slipped under the inferior cornu of the saphenous opening and the fascia lata is divided along this. In early cases, where the vein is simply overfull, division of the fascia for about an inch is all that is required, and the wound may then be closed. In more advanced cases, where the wall of the vein is thickened, the fascia may be divided to the lower end of the wound—i.e., for a distance of 4 or 5 inches. The margins of the incision in the fascia are dissected slightly back and the vein is displaced from the superficial tissues into the bed which is thus prepared for it. The fascia is now sewn over the vein by a continuous suture of fine catgut which commences above at the saphenous opening and extends to the lower end of the incision in the fascia, care being taken to leave the lower half inch or so in order to avoid constriction of the vein. In these manipulations the vein is treated with the utmost gentleness. It should not be dissected too bare; indeed, it is a good thing to see a little of the superficial fat adherent to it. It should not be seized by dissecting forceps, but may be conveniently manipulated by using an aneurysm needle as a retractor. Small tributaries may be ligatured and divided, but it is desirable to preserve a large branch on the outer side and probably a smaller one on the inner side, each situated a small distance below the saphenous opening. When suturing the fascia over the vein a small lateral slit may be made in the fascial margin in order to avoid constriction as they join the main trunk. As a general rule, the upper few inches of the vein only need be embedded, and in a great many cases simple division of the margin of the saphenous opening is all that is called for.

When the lower half of the internal saphenous in the thigh is tortuous and varicose the affected portion should be excised, and the upper half may then be treated in the way described; it is important under these circumstances to preserve the lateral tributaries. When the whole vein is varicose transplantation beneath the fascia is contra-indicated; nor should tortuous varicose veins be so treated. In such cases, if operation is decided upon, excision of the vein should be carried out, or Trendelenburg's operation; in any case the prognosis as regards recurrence is not hopeful.

Special Indications for this Operation.

This operation should not be performed indiscriminately, but only on carefully selected cases. In addition to the well-recognised rules for excision the following special indications must be present.

1. The patient must be a young adult, or, if of middle age, the general condition must be satisfactory.
2. The varicosity must affect the lower part of the internal saphenous and its tributaries. Both legs may be affected, but whether unilateral or bilateral the disease must not be generalised.
3. Other causes for the condition must be absent, and there must be some evidence to suggest that there is obstruction at the saphenous opening. This is usually indicated by a thickened and dilated condition of the saphenous, which, however, is not tortuous and varicose. The over-distended vein will readily be felt and probably seen when the patient is examined in the erect position. This I believe to be an early condition, in which excision and removal of the cause offers a good prospect of cure; if it is allowed to extend the condition will become unsuitable for operative treatment. I have performed the operation in about 20 cases, and I believe that the results are better than when excision is practised alone.

Non-Operative Treatment.

In cases unsuitable for operation some form of support, either an elastic stocking or a bandage, will be necessary, in addition to any hygienic or general treatment which may be indicated. Elastic stockings should be made to measure and require frequent renewal. On this account bandages, either elastic crepe or elastic web, are more often employed. The bandage should be put on in the recumbent position, the leg having been raised so as to empty the veins as much as possible before its application.

PHILIP TURNER, M.S. Lond., F.R.C.S. Eng.,
Surgeon, Guy's Hospital.

Public Health Services.

THE WORKING OF THE LEICESTER PUBLIC MEDICAL SERVICE.

THE ability of doctors to run a public medical service on a large scale has been the subject of recent discussion, but the acceptance by the insurance medical service of the Minister of Health's offer renders further discussion at present largely of an academic nature. The question of the extension of medical benefit to the wives and children of insured persons is, however, likely to be raised by the Royal Commission when it meets. Such a service on a small scale, outside the present range of the National Insurance Acts, is now actually in being, and we are indebted for the following description of the Leicester Public Medical Service to Dr. W. Moffat Holmes, honorary secretary, Leicester Subdivision of the Union of Medical Practitioners and Leicester Public Health Service. Dr. Holmes says:—

The Leicester Public Medical Service is worked under the ægis of the Leicester Subdivision of the Union of Medical Practitioners, so that it is advisable to say something also about the parent body, which is a registered trades union and of which one of the objects is "the promotion of an equitable system or systems of medical service regulating the medical attendance and treatment by members of the Union and the provision by them of medicines for persons unable to pay the ordinary medical charges in the usual manner." In accordance with the foregoing quotation, the Leicester Public Medical Service was inaugurated in January, 1913. There are many advantages accruing to members of the Union, and membership thereof gives to a practitioner the right to have his name entered on the panel of medical practitioners prepared to practise in connexion with the Public Medical Service.

When the work of the Leicester Provident Dispensary came to an end on the introduction of the National Health Insurance Act a large section of the population of Leicester (chiefly women and children) who were members of that institution, unable in most instances to pay ordinary medical fees, were left unprovided for in the matter of medical attendance. In these circumstances the medical profession in Leicester introduced the Public Medical Service, through which dependents of insured persons, and others, are enabled to obtain medical attendance when necessary, by means of small periodical payments.

1. *Subscriptions.*—Uninsured persons over 14 years of age, entered alone on card, pay 3*d.* per week, but a man and wife pay 5*d.* per week. On cards where a child or children under 14 years of age are entered on a card with an adult, the adult pays 2½*d.* per week, the first child 2*d.* per week, the second child 1½*d.* per week, and the third and fourth 1*d.* each per week, not more than four children being charged for in one family. On cards where no adult is entered the first child pays 2½*d.* per week, the second 1½*d.* per week, and the third and fourth 1*d.* each per week. The entrance fee is 1*s.*, the card costs 3*d.* Persons in receipt of the Old Age Pension, or receiving assistance from the guardians, are charged 1*d.* per week less than the ordinary rates. This payment entitles them after the expiration of one month from date of application for membership to ordinary medical attendance and medicine, dressings, &c., and if they are unable to go to the doctor's surgery or consulting room, the doctor visits them at their own homes. Patients desiring to be visited at their own homes must send their messages to the doctor's surgery before 10 o'clock in the morning to ensure attendance on that day, otherwise they are liable to be charged a fee. Night calls—i.e., visits made between 8 P.M. and 9 A.M. in response to calls received within these hours—are also charged for. This arrangement was made chiefly to deter subscribers from sending for the doctor unnecessarily, with the result that, comparatively speaking, very few night calls are received. Persons actually ill at time of application for membership pay a sick fee of 10*s.* in addition to the ordinary rates, which entitles them to immediate attendance. The weekly subscriptions have been fixed at these low rates because the subscribers receive no aid from the State, and because the medical men are desirous of continuing the humane and charitable work associated with the profession in regard to deserving cases. Moreover, it was found expedient to arrange a graduated scale of contributions in cases where there are a number of children in a family, because the experience in Leicester has proved that it is, generally speaking, the lowest paid labouring classes who have the largest families, and who are least able to pay. In other circumstances the subscriptions would be higher.

2. *Control.*—The Public Medical Service in Leicester is under the control of a board of management consisting entirely of doctors, elected annually, with various committees. All the doctors in Leicester are associated with the Public Medical Service in either an honorary or an acting capacity.

3. *Premises, Staff, &c.*—There is a central dispensary and offices, and eight branch dispensaries in various parts of the town. At the central dispensary, and at five of the branch dispensaries, there are consulting rooms. The doctors do not dispense, prescriptions being made up at the central dispensary and branches by qualified dispensers. The staff consists of a manager, chief dispenser, dispensers, collectors, clerks, porter, and caretakers. The profession in Leicester have been very fortunate in having, from the inception of the scheme, the services of the present manager, Mr. T. W. Lawrence, whose administrative ability and knowledge of medical matters generally have been of inestimable value.

4. *Drugs.*—The drugs, chemicals, &c., required at the branch dispensaries are supplied from the central dispensary, to which is attached a steam laboratory. A pharmacopœia containing over 150 formulæ, published by the Public Medical Service, facilitates both prescribing and dispensing, and is recognised under the National Health Insurance Act.

5. *Change of Doctor.*—Members have choice of doctor from a panel of more than 60 doctors, and are allowed to change doctor quarterly, or more frequently in the event of removal to another part of the town. All members are able to consult the doctor of their choice at his surgery, and in several cases at the consulting rooms of the Public Medical Service in addition. Each doctor has submitted to him the names and addresses of applicants for admission to the Service who desire to be placed on his list, and he has the right to accept or refuse.

6. *Specialist Treatment.*—Members have the advantage of specialist treatment for eye, nose, ear, and throat on payment of very moderate fees, and dental treatment is also arranged for.

7. *Friendly Society Arrangements.*—As all the societies in Leicester making arrangements on contract lines for medical treatment of their uninsured members do so through the Public Medical Service, it is possible to offer a choice of arrangements to the members. The large majority favour the arrangement whereby medicines can be obtained at the central dispensary and branches. Members of another section can get their prescriptions dispensed at the pharmacists'. Members of the friendly societies can obtain their medicines at the dispensary of the Medical Association attached to their societies. The members of the various sections of the Public Medical Service have free choice from the same panel of doctors.

8. *Complaints Committee.*—At the inception of the Service in Leicester a complaints committee was set up, consisting of four representatives of the friendly societies, four representatives of the medical profession, of whom two should not be "acting members" of the Service, with an independent chairman, to investigate any complaints that might be made by members. Were any proof needed of the satisfactory nature of the attendance given to members of the Public Medical Service, it is found in the fact that the committee has never had occasion to meet.

9. *Philanthropic Arrangements.*—The Public Medical Service gives free medical treatment to members of the Institution for the Welfare of the Blind, the Wycliffe Society, the Cripples' Guild, and the Home for Feeble-Minded Girls.

10. *Dispensing for Outdoor Sick Poor.*—The Public Medical Service has since Jan. 1st, 1913, by arrangement with the board of guardians, approved by the Local Government Board, dispensed the necessary medicines for the outdoor sick poor of Leicester, and the satisfactory nature of the arrangement is proved by the fact that not a single complaint has been made by the guardians, and that the Local Government Board has approved of the arrangement being renewed year by year.

11. *School Clinic.*—The Public Medical Service, by arrangement with the Education Committee, provides accommodation for the dental and other treatment of school-children.

12. *Regional Medical Officer.*—Accommodation is also provided at the central dispensary for the regional medical officer, by arrangement with the Ministry of Health.

It will be readily perceived that the services rendered, and the accommodation provided, as set forth in the three preceding paragraphs, are a source of income.

13. *Statistics.*—The successful nature of the work as a whole is indicated by the following figures: the number of uninsured

members exceeds 40,000; prescriptions dispensed annually, number about 195,000. This result has been achieved on purely voluntary lines, no canvassing by collectors being allowed. The collectors are paid by salary and have no commission.

14. *Hospital Accommodation.*—Adjacent to the central dispensary, and under its own separate management, is the beautifully fitted Faire Hospital of three wards, each containing nine beds. This hospital, which is a model of its kind, takes its name from Mr. John E. Faire, J.P., of this city, who was primarily responsible for the hospital being built, and has done such great work for it since its inception. In this hospital, largely owing to Mr. Faire's generosity and foresight, Leicester possesses a very valuable institution. There are two operating theatres, electric lifts, &c., and medical and surgical cases are received at certain fixed charges for nursing and maintenance. Patients can be attended by their own doctor, and the fee for operation or attendance is mutually arranged between doctor and patient. Also adjoining the central dispensary is the Leicester and Leicestershire Maternity Hospital. The Public Medical Service supplies to both hospitals drugs, chemicals, dressings, &c., and to the latter steam for heating. The work of the Leicester Public Medical Service is quite distinct from the medical service of the National Health Insurance Act.

The Insurance Committee has no connexion whatever with the Public Medical Service, *nor is there lay control of any kind.* Furthermore, the following points in connexion with the work of the P.M.S. may be emphasised: (*a*) No outside interference; (*b*) no records to be kept; (*c*) no irksome regulations in connexion with certificates or any other matter.

The organisation of the Public Medical Service in Leicester is capable of expansion to almost any extent, without any violent upheaval, and should the necessity arise for making other provision for medical treatment of the persons who now receive their medical benefit under the National Health Insurance Act, the Public Medical Service could cope with the situation quite readily. Moreover, the Service is a satisfactory one and acceptable to the subscribers generally. Indeed, it is spoken very highly of, not only by the patients, but by influential men connected with the friendly societies in Leicester, and by independent gentlemen who have made inquiries amongst the working classes.

The Leicester Subdivision of the Union of Medical Practitioners.

For the last five years a scheme for collective locum-tenencies during holidays or sickness, devised by Dr. E. Lewis Lilley, has been successfully carried out. As illustrating the working of this scheme, during the period from April 1st to Sept. 30th, 1922, 17 doctors took advantage of the scheme and contributed £201 to the pool. The expenses amounted to £5 9*s.* 8*d.*, being cost of cards, posters, stationery, &c., leaving £195 10*s.* 4*d.* for distribution amongst the practitioners who attended patients under the scheme.

Financial.—It may be of interest to the profession to know that the practitioners on the panel in Leicester agreed, almost unanimously, to a levy being made annually of 1*d.* per annum for each insured person on their lists. This enabled the Committee in the year 1922 from the fund thus created—

(*a*) To meet the expenses of the Leicester Subdivision of the Union.

(*b*) To defray the expenses of the Panel Committee.

(*c*) To contribute £185 to the National Insurance Defence Trust.

(*d*) To provide £35 for the medical representation in Parliament Fund.

(*e*) To raise the sum of more than £100 for medical and allied charities, of which £50 was forwarded to the Royal Medical Benevolent Fund, £5 5*s.* to the fund for the relief of Russian doctors, and the remainder distributed locally.

Members of the Union can effect insurances on very advantageous terms, and the solicitors to the Union undertake for members the recovery of debts, on payment of a moderate commission. Members of the Union are also entitled to free legal advice in certain circumstances.

Other Details.—The Central Building, East Bond-street, Leicester, affords facilities for arrangements of a collateral nature being made. Hence, in addition to the activities of the Public Medical Service, the meetings of the Local Medical and Panel Committees, and of the Leicester subdivision of the Union of Medical Practitioners, are held there, the personnel of these committees being practically identical with the board of management of the P.M.S. The meetings of the Leicester Medical Society are held in this building and the library of the Society is housed there, as also is the Leicester Medical Club. It will thus be seen that the Central Building of the P.M.S. is the centre of medical activity in Leicester, and with the various interests being so interwoven and linked up, it has tended to make the medical profession in this city a progressive and united force, and has greatly increased good fellowship among them.

In my opinion, the inauguration of a system of public medical service by the medical profession throughout the country is a step that should be taken, and taken promptly. Not only does it provide facilities for women and children of the working classes to ensure medical attendance by means of small periodical payments, but it is a system entirely free from outside interference, and the central organisation is exceedingly useful in dealing with the mass of detail now inseparably associated with matters pertaining to the medical profession. The board of management are anxious that their experience of the last ten years shall be made available to the whole of the profession. With that end in view they will be pleased to receive members of the profession at any time, but extend a special invitation for Friday, Nov. 30th, when the officers of the Service will be in attendance and will be glad to welcome all who can make it convenient to attend.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following table gives some of the principal health statistics of four counties for 1922:—

Name of county.	Estimated population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
							Infant mortality		
			All causes.	Tuberculosis.	Cancer.	Respiratory with influenza.	Legit.	Illegit.	Maternal mort. in childbirth.
Derbyshire ..	595,980	22·0	10·8	0·8	1·0	2·0	70	117	4·0
Essex	917,414	18·6	11·1	0·9	1·2	2·2	51	116	3·2
Isle of Ely ..	74,653	21·0	12·0	0·7	1·4	2·1	57	131	3·8
Dumbartonshire	55,343	22·3	12·7	1·0	1·1	3·1	(80)*		5·7

* The figure in brackets gives the undivided infant mortality rate.

Derbyshire.

Dr. Sidney Barwise reports that in three areas in the county a whole-time medical officer of health is employed by the local sanitary authorities, who also carries out certain duties under the county council, and that the Ministry of Health have suggested that the county council might confer with the local sanitary authorities with a view to the extension of this system as opportunity offers. Dr. Barwise thinks that if this policy is agreed upon, the sanitary administration of the county in the course of 10 or 15 years, without any sudden change, will be placed upon a much more efficient basis. Speaking of the neglect of vaccination, Dr. Barwise thinks we ought to have powers for the compulsory vaccination of all contacts. He also makes the suggestion that a scheme might be devised by which the cost of treating cases of small-pox unprotected by vaccination would be borne by the unvaccinated. During the year some thousands of circulars have been distributed giving information on the subject of cancer. Dr. Barwise attributes the fall in infant mortality to the increase of breast-feeding, better artificial feeding, the sterilisation of milk, and the substitution of dried milk for carbohydrate foods.

The cost of the Ashbourne maternity home was £2 2*s.* per week and of the Ripley home £3 7*s.*, while the average of 55 maternity homes receiving Government grants was £4 14*s.* 9*d.* Dr. Barwise thinks more provision should be made in these homes for paying patients. Midwives attended at the birth of 10,168 infants, leaving 2927 presumably attended by medical practitioners. Midwives sent for medical help in 1229 cases. There were 30 cases of puerperal fever with 17 deaths, and of the deaths 7 occurred in the practice of midwives. In one case of post-partum hæmorrhage no midwife or doctor had been engaged, and the patient died before a doctor could attend. Three deaths took place after Cæsarean section in hospital. Of the eight deaths from eclampsia six might be regarded as preventable. Dr. Barwise thinks the coöperation of the medical profession in an investigation into maternal mortality should be invited and that the council should pay for a detailed report on the circumstances of every such death.

A full review is given of the tuberculosis problem. Dr. Barwise sets out to consider in what direction expenditure in these days of restriction will give the best value, and concludes that there is nothing to be undone, but that Derbyshire ought to proceed steadily to the completion of its scheme by the provision of a pavilion for advanced female cases at Walton and the development of the Bretby estate both as an open-air residential school and a sanatorium for the pre-tuberculous type of child with both bone and joint and lung disease. A letter from the Ministry, dated March 23rd, 1923, is quoted praising the efficiency of the Derbyshire scheme and pointing out the need for these additions thereto. Dr. Barwise thinks that much in the way of the building up of resistance may be achieved by the encouragement of gardens and allotments in which people can grow their own vegetables, and by the provision of open-air schools, both day and residential. Dr. Barwise appears to fear that if milk is made tubercle-safe, we shall get rid of bovine tuberculosis at the expense of losing some of our immunity to human tuberculosis. He considers that after three years of age the child should take its risk in acquiring immunity through a tuberculous gland by being given small doses of the ordinary raw milk of commerce, but never from the milk of a single cow. This experiment would have its dangers, and, on the whole, we think that most sanitarians, under present circumstances, will be inclined to accept Louis Cobbett's pronouncement that the harm done by the bovine bacillus is certain, the benefit it confers is problematical.

As regards the prevention of massive infection, Dr. Barwise comments on the prohibitive cost of segregating advanced consumptives, and instances a case discharged two years ago who cost the county £600 during his five years' isolation and is still alive though unable to work. He thinks that more might be done by home supervision in such cases, following a short educational course in an institution. He also thinks that when the advanced case is the mother, it would be better and cheaper to board out the children with foster parents in the county than to segregate the mother. Attention is drawn to the fact that there are 18,000 empty beds in Poor-law infirmaries available for the stage in which no treatment is required other than a clean bed and food. The examination of the sputum of children by the Ellerman and Erlandsen concentration method continues to be of great value. Good results are reported from quartz-lamp treatment (Bach technique), especially in the case of tuberculous glands and lupus. Dr. Barwise thinks a charge should be made to those who can afford to pay for treatment at the V.D. clinics, and he also emphasises the fact that in a county area the treatment of gonorrhœa can only be satisfactorily carried out by general practitioners.

The resolutions of the Mental Deficiency Act and Mental Hospital Committees advocating the sterilisation of mental defectives convicted of sexual offences and the voluntary sterilisation of unimprovable male defectives are quoted with approval. Under "Water Supply," it is pointed out that the sanitary authorities in the watershed of the Trent have not taken sufficient advantage of the right to take water from the Derwent Valley water mains secured for them by the county council. Progress is reported in the matter of sewage disposal schemes. As regards the milk question, Dr. Barwise thinks we ought to strive for clean tubercle-free raw milk delivered in bottles rather than content ourselves with the pasteurised product.

Essex.

Dr. W. A. Bullough reports that the London County Council have continued the arrangement by which the services of Dr. W. McC. Wanklyn are made available for the help of any medical officer of health in the administrative county in the event of suspected small-pox. During 1922 five such applications were made, and in each case Dr. Wanklyn was satisfied that the disease was not small-pox. The tipping of refuse on the Essex marshes along the northern bank of the Thames has again come under consideration. A conference of representatives of the Ministry of Health, the London County Council, the City Corporation, and the Metropolitan Borough Councils was held in June, and it was pointed out that, owing to the need for economy, tipping must continue for a long time, and as a result the Ministry have drawn up a list of precautions for abating and preventing nuisances arising from refuse-tips. An unusual nuisance, apparently caused by oil refining, has given rise to many complaints in south-east Essex. The nuisance consists of offensive smells with flavours resembling those of benzine and garlic. The sanitary authorities chiefly affected are those of the borough of Southend-on-Sea and the rural districts of Rochford and Orsett. Consultations have been held with the Ministry and proceedings suggested under the nuisances clauses of the 1875 Public Health Act. Some improvement has taken place, but complaints have again arisen.

The number of persons in the county living more than two to a room was less favourable at the 1921 Census than it was in 1911; 70 per cent. of the families have separate houses, 26 per cent. live two in a house, and 4 per cent. live three or more in a house. In the administrative county 4407 houses were erected in 1921, 2584 by local sanitary authorities and 1823 by private enterprise. Dr. Bullough has nothing but praise for the council houses erected in Essex. The only drawback is that the rents are beyond the means of the tenants, who are often compelled to sublet a portion of the house. On June 15th a conference was held, on the invitation of the Ministry of Health, for the purpose of forming a joint committee for town-planning the region on the northern bank of the Thames extending from Shoeburyness to East and West Ham. Unless steps are taken Dr. Bullough points out that houses will be erected on low-lying unsuitable sites.

The County Council and the County Nursing Association continue to work in the closest coöperation. Dr. Bullough looks forward to the time when the whole of the rural parishes will be served by district nurse-midwives. Owing to the need for economy, the Association is only able to establish five new associations per annum. There are now 126 district nursing associations affiliated to the County Association, and of these 113 participate in the County Council's combined nursing scheme. Dr. Bullough regards the nurse-midwives as one of the most important factors in promoting the health and well-being of the community. In addition to their work as district nurses and midwives, they now coöperate with the county health visitors, by following up defects amongst school children, by carrying out tuberculosis after-care, and maternity and child welfare work, &c. In the rural parts of the county, says Dr. Bullough, there is no one more fitted to carry out the task of improving the individual's environment and knowledge of the laws of hygiene and health than the district nurse-midwife.

Isle of Ely.

Dr. J. Pixton Walker, who succeeded Dr. Percy Moxey as county medical officer of health on Oct. 31st, 1922, presents his first annual report. He states that the year has been one of uneventful progress. The Isle of Ely does not support any general or special hospitals, and in such circumstances the tuberculosis clinics at Ely, March, and Wisbech have continued to do good work and fulfil a long-needed want. During the year 30 patients were sent to sanatoria outside the county. Dr. Walker draws attention to the extensive use of goats' milk in the Isle and the advantage that goats are rarely affected with tuberculosis. Addenbrooke's Hospital, Cambridge, is now the only available V.D. treatment centre since the clinic at Peterborough was closed.

Dumbartonshire.

In the absence, through illness, of Dr. Thomas Lauder Thomson, Dr. Alexander Johnstone presents the annual report, and states that the county has been free from any serious outbreak of infectious disease during 1922. No further progress has been made towards the erection of a county sanatorium. In the western district the beds set aside for tuberculosis at the Dumbarton Joint Hospital have been constantly occupied, but there is difficulty in persuading patients to make use of the 20 beds set aside by the Dumbarton Poor-House Combination in the poor-house grounds. The need for an after-care organisation is pointed out. Better accommodation is required for the maternity and child welfare centre serving the Vale of Leven. There were two outbreaks of foot and mouth disease in the eastern district. In one case the milk was all made into butter, and the point arose as to whether under the existing law a local authority has the power to suspend a supply of butter made from the milk of infected cows.

SCHOOL MEDICAL SERVICE.

Dumfriesshire.

OF a school roll of 12,711, 5089 children were examined in the code groups, and 4063 special examinations were made. Of those examined in the code groups only 9·33 per cent. were free from defect. Nearly 40 per cent. showed nutrition below average, although only two could be classed as "bad" nutrition; 38 had discharging ears, 16 were markedly deaf, and 110 were found to be dull and backward. Treatment is so far confined to visual defect and dental decay. Of 1942 children dentally inspected 55 per cent. were found to require treatment, and Dr. John Ritchie reports that 62 per cent. of these availed themselves of the school dentist's services.

Stockport.

The school population here is 16,700, and during 1922 the number of children inspected in the routine groups was 5680. Of these 33·6 per cent. were found to require actual medical treatment. The total number inspected by the school dentist was 2500, of whom 2072 received treatment. The staff consists of the medical officer of health, Dr. W. H. Rowell, who is also medical officer to the Education Committee, a school medical officer, an assistant school medical officer, and three nurses. There is a central school clinic where work goes on all day, and a branch clinic is open one afternoon a week. The attendances at the clinics for the year amounted to 10,772, representing 2772 children; 1631 of these suffered from skin affections. There are 125 child cripples in this county borough, 27 of these being crippled by tuberculosis, and the majority of the remainder by infantile paralysis. When seen by the school doctor they have usually reached a stage where treatment is not satisfactory. Twelve stammering children were treated by a course lasting six weeks. A "following up" class was held each Saturday morning, of which a large proportion of the children took advantage. Of the 12, 7 were considered cured and 5 improved.

St. Helens.

Of an average roll of 18,194 elementary school children 10,162 were medically examined, and of these 38 per cent. showed defects. By the end of 1922 64 per cent. had received treatment. The medical officer of health, Dr. F. Hauxwell, is also the school medical officer, and the three assistant medical officers of health are also assistant school medical officers, their time being so divided that the school medical service has the equivalent of one whole-time officer. Dental inspection and treatment are carried out by a whole-time dentist who gives five-sixths of his time to school work and the remaining sixth to tuberculous patients. The town is divided into 14 districts, each having a health visitor, who is responsible for the maternity and child welfare work, tuberculosis, infectious diseases, and school nursing. In this way she gets to know family conditions well, and is therefore of great assistance to the school doctor.

MENTAL HOSPITAL REPORTS.

THE annual report of the *Glamorgan County Mental Hospital, Bridgend*, an exceptionally large institution accommodating nearly 1800 patients and possessing five medical officers, unfortunately gives an impression of considerable friction with the local authorities in regard to electric and water supply, and in regard to the report of a committee which apparently made unfounded criticisms as to the administration of the hospital. The commissioner's report, which is reproduced, suggests a number of possible improvements: The clothing of the women is unattractive. an insufficient number of night garments is provided. and some patients are obliged to undress in the day-rooms; no patients are provided with slippers. The methods of dealing with soiled linen are criticised, and the necessity of bacteriological examination in cases of diarrhœa is emphasised. Money allowances should be made to patients going on leave. A regrettably small proportion of the nursing staff enter for the examinations of the Medico-Psychological Association. The improvement of classification and accommodation is being considered. The difficulties of administering an institution of such unusual size as this are very great, and under different economic conditions it would, no doubt, be reconstructed on a different plan.

The annual report of the *Coppice Mental Hospital, Nottingham*, which is largely maintained by voluntary contributions, shows a satisfactory financial position at the close of the year. The number of recoveries recorded has only once been exceeded in the long history of this hospital, and the management have reason to be satisfied with a successful year's work.

No feature of special interest is to be noted in the annual report of the *Roxburgh District Asylum*. Certain structural alterations have been made which will afford better accommodation for some of the female patients. A somewhat grandiloquent effect is achieved in the chairman's report by recording the average number of patients under various heads to three points of decimals; the medical superintendent, in reproducing the same figures, contents himself with one point only.

The most important feature in the report of the inspector of *Hospitals for the Insane, Queensland*, is no more than a prophecy. There is every prospect that the increase in the general population will necessitate the building of another asylum, and it is urged that the plans and site should be brought under consideration without delay. It is interesting to note that a thorough investigation showed extensive hookworm infection in two of the asylums, stool examination being positive in no less than 477 cases.

ROYAL MICROSCOPICAL SOCIETY.—The section of the Society which has been formed to deal with the Industrial Applications of the Microscope will hold its next meeting at 20, Hanover-square, London, W., on Nov. 28th, at 7 P.M., when Mr. Conrad Beck will show a new projection microscope for measuring fine wires and fabrics to 1/50 000 inch, and Messrs. Adam Hilger, Ltd., will show Dr. Müller's X ray spectrograph for the examination of sub-microscopic crystalline structures. At 7.15 a lecture demonstration will be given by Mr. J. E. Barnard on the Characteristics of a Microscope for General and Special Purposes; the Tests for Mechanical Efficiency that should be Satisfied. At 7.45 there will be an inspection of exhibits, and at 8 o'clock communications will be read by Dr. Sidney H. Browning on the Application of the Microscope to Industrial Diseases and by Mr. Charles A. Newton on the Microscope in the Examination of Condensed Milk, Sir Kenneth Goadby presiding.

Special Articles.

SCOTLAND.

(From our own Correspondents.)

The Edinburgh Obstetrical Society.

At a meeting of this Society, held on Nov. 14th, Dr. J. Lamond Lackie, the retiring President, delivered his valedictory address in which he reviewed recent advances made in obstetrics. Progress in this field, he said, was in many directions very striking but in others disappointing. Among the unsolved problems of obstetrics, none called more urgently for solution than that of the toxæmias of pregnancy. Round this there had accumulated a large literature, but unfortunately none of the theories was based on such incontrovertible evidence as to afford a reliable basis for prophylaxis and treatment.

The Toxæmias of Pregnancy.

Investigations of recent years pointed to the placenta as the probable source of the toxin. In this connexion Dr. James Young, of the Society, had advanced the view that products of placental necrosis might cause the phenomena of eclampsia. Recent biochemical research on renal and hepatic function suggested that in eclampsia the metabolic factor was not of so great a significance as Watson and Harding had shown must be assigned to it in the earlier months. While this was so, the lowered incidence of eclampsia in war years, especially on the continent—probably as a result of a diet poor in protein—suggests that the dietetic factor was of first importance. The Dublin method of treatment, which was yielding good results, was based on this hypothesis. It was previously the routine in the maternity hospital to avoid morphia in eclampsia. Now it was administered to control the seizures. Many believed that veratrone (a preparation containing the equivalent of 15 mins. of tincture of veratrum to the c.cm.) was a far better remedy than morphia—it certainly had a remarkable effect in lowering blood pressure and as a depressant to the central nervous system. Care must, however, be exercised as in large doses its depressing effect on the heart might be alarming or even fatal. It had been shown by statistics that the cases which could be classified as severe might be expected to show a mortality five times as great as those classified as mild, no matter what method of delivery was employed. Also the figures showed that the cases in which there was less obstetric interference showed much the best results. With regard to hyperemesis and also the so-called physiological morning sickness, there were evidences of a disordered metabolism showing itself as a glycogenic disturbance in the maternal liver. Other subsidiary but important factors were the neurotic factor, which through the sympathetic nervous system acted on the glycogen stores of the liver, the intestinal intoxication factor, the dehydration factor, the reflex factor, and the patient's health at the time of conception. Cases were classified as mild, moderate, or severe, and treatment consisted in a protein-free diet with the administration of carbohydrate, and glucose in particular.

The Treatment of Hæmorrhage: Indications for Cæsarean Section.

Regarding hæmorrhages in later months of pregnancy, the most striking advance was in the treatment of some by Cæsarean section. The pathology of concealed accidental hæmorrhage had been carefully studied, and it was now known that in a severe case the damage to the uterine muscle might be so severe as to have disastrous consequences. For that reason, many held that in concealed accidental hæmorrhage the safest treatment was Cæsarean section followed by hysterectomy. Of late the tendency was to try to save the uterus. The most recent theory as to the cause of accidental hæmorrhage was that it was a mechanical one, of the nature of an obstruction of the venous return from the uterus. The treatment of placenta prævia by Cæsarean section was an innovation of the last 20 years and in some cases it was doubtless the best line of treatment. Generally, however, especially in multiparæ, bipolar podalic version was the most favoured treatment, but in a primipara with a rigid os Cæsarean section was the most satisfactory means of saving both mother and child. Pressure on the placental site by a Champetier de Ribes was advocated, as many infants might be saved if this means of controlling hæmorrhage were used instead of by pressure of the breech on the bleeding site. By this method there would be no interference with the child till the actual moment of delivery and perhaps not then. There was no more difficult task for an obstetrician than to determine the best management of a case of slightly contracted pelvis. High forceps were to be avoided except on rare occasions; indeed, it was thought that forceps had been used too frequently for all indications. The maternal and fœtal mortality from the high forceps operation was greater than properly chosen and properly timed Cæsarean section. In recent years Cæsarean section had become so safe that there was risk of the indications becoming too numerous, and many Cæsarean sections were undertaken without real justification. In eclampsia it had not proved successful, but in cases of heart disease complicating pregnancy and labour, even uncompensated cardiac disease, the results so far published were good. Also the patient could be sterilised at time of operation.

The technique of the operation varied with different operators, and the suture material was a subject of much debate, but the strength of the scar probably depended more on the absence of sepsis than on the material used. Pubiotomy was an old operation and had been revived more in other countries than in this. It was an operation to be adopted only when forceps had failed and conditions contra-indicated Cæsarean section. It ought to compete with craniotomy, which he hoped in the future would only be reserved for cases of hydrocephalus or where the child was already dead.

The Use of Drugs in Labour.

The most striking therapeutic agent that had been introduced into obstetrics was the extract of the posterior lobe of the pituitary gland. It was very effective when used to bring on labour about full time, but less so in the induction of premature labour. During labour its application had been much abused, and during the second stage its employment was fraught with great danger. Cases should be carefully chosen; if not, there was great danger of laceration of the parts and even of rupture of the uterus. As a stimulant to the uterine contraction in the third stage it was very useful. As regards the management of labour, a great advance had been the employment of morphia-scopolamine narcosis. The only deterrent to its general use was its alleged dangerous effect on the baby.

Advances in Gynæcology.

In gynæcology the pathology of pelvic tumours and other lesions were more completely understood, and the large part played by venereal diseases in the causation of gynæcological disorders was being more appreciated. No subject had been more discussed than suppurative salpingitis. Some believed in immediate operation, others in expectant treatment and interfering when acute symptoms had subsided and chronic tubal disease and ill-health demanded it. Intrinsic dysmenorrhœa was still a vexed question and the opinions as to its causation and treatment, medical and surgical, were very diverse. Prof. Blair Bell had pleaded for a more accurate study of the pathology of the condition and for a clearer definition of the various causes of the pain. Radiotherapy, both by X ray and radium or by both, had come rapidly to the front as a method of treating gynæcological cases. It should be regarded not as an opponent of surgery, but as an alternative when operation seemed contra-indicated. Great benefit has been shown by its use in many varieties of gynæcological conditions.

With regard to endocrinology, it was well known that many conditions had as their basis some aberration in endocrine function and a great deal of work had been done with regard to it. In spite of that, the knowledge of the physiology of the glands of internal secretion was far from complete, therefore there was as yet no rational basis for organotherapy, which was largely empirical and often disappointing. With a fuller knowledge of the physiology of the pelvic organs conservative gynæcological surgery had come to be more practised. Ovarian tissue was less seldom sacrificed than formerly and conservative surgery of the Fallopian tubes more practised than formerly. It was less frequent to perform hysterectomy for uterine fibroids than previously was the case.

Dr. Lackie then welcomed his successor, Prof. B. P. Watson, to the presidential chair of the Society.

Glasgow.

Gifts to Glasgow University.

The museum in the new zoological building of the University is to be enriched by a collection of British insects, presented by Mr. A. H. Bishop, of Glasgow, and his son. The collection includes a large number of mounted and labelled specimens, forming an almost complete set of British coleoptera and a representative set of lepidoptera, a large number of unset specimens, and many works on entomology. Prof. Graham Kerr points out the value of such a collection in view of the close inter-relation between medicine, economic zoology, and entomology. Prof. Bryce also intimates that Dr. Knight, of Queen's Park Higher Grade School, has presented to the department of anatomy "a valuable osteological preparation, a series of models of the brain, and 300 lantern slides of photomicrographs of the tissues and organs of the body."

Glasgow Hospital for Women.

The annual meeting of the subscribers to the Glasgow Hospital for Women was held on Nov. 12th. Outdoor consultations for the year numbered 4050, and there were 225 operations performed. The extraordinary revenue enabled the directors to meet a deficiency of £631 in the ordinary revenue, and to add £836 to the capital account. The hospital is intended for women, who, while unwilling to enter a public hospital, are nevertheless unable to meet the expense of a nursing home, and their subscriptions have given the hospital invaluable financial support during the past year.

Death of Dr. Archibald Sloan.

We regret to announce the death of Dr. Archibald Sloan, which occurred at his residence in Glasgow on Nov. 15th. Originally a teacher, after graduation Dr. Sloan built up a large practice in Glasgow, and was at one time casualty surgeon to the Northern Police Office and physician to the Glasgow Central Dispensary. Dr. Sloan was for many years a member of Glasgow School Board, and took an especial interest in the physical training of children, in school medical inspection, and in the feeding of necessitous children. He had been for the last 15 years medical officer to the Glasgow Provincial Committee, and was a manager of the Western Infirmary and of the Broomhill Homes.

Sir Donald MacAlister, Principal of the University of Glasgow, has been appointed a deputy lieutenant for the city of Glasgow.

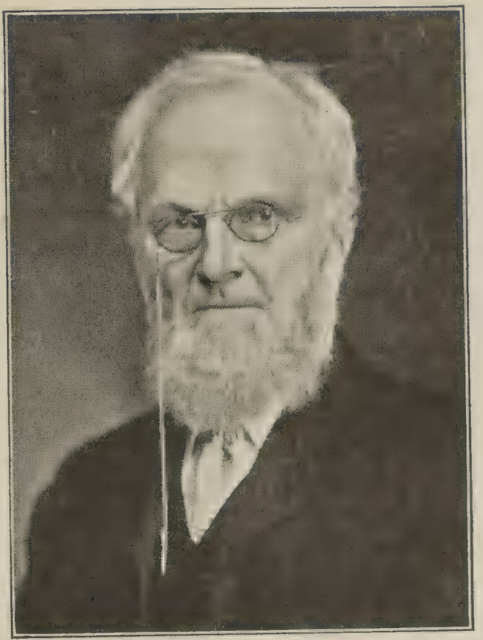
The People's League of Health Endowment Fund.—H.R.H. the Prince of Wales has given £20 in support of the appeal of the ex-Lord Mayor of London (Sir Edward C. Moore) on behalf of the £100,000 Endowment Fund of the People's League of Health, of which the King is patron.

Obituary.

THOMAS PRIDGIN TEALE, F.R.C.S. Eng., M.B. Oxf., F.R.S.,

CONSULTING SURGEON TO THE LEEDS GENERAL INFIRMARY.

We announced last week with deep regret the death of Mr. Thomas Pridgin Teale, the famous Leeds surgeon, which occurred on Nov. 13th at his house, Headingley, Leeds. He was by four years the senior Fellow of the Royal College of Surgeons of England, having obtained that diploma in 1857, and had reached the advanced age of 92 at the time of his death. He had a pedigree which pointed directly towards the fame which he obtained as man of science, surgeon, and sanitarian. His father, himself the son of a Leeds surgeon, was Thomas Pridgin Teale, F.R.C.S. and F.R.S., one of the originators of the Leeds School of Medicine, where he was lecturer for many years on anatomy and physiology, and where he made a name as a surgeon which is perpetuated in text-books by the original advice which he gave in connexion with amputations and urethral surgery. He was one of the Crown nominees on the first General Medical Council in 1858. His wife, and the mother of the subject of this notice, was the daughter of the Rev. Charles Isherwood, a Fellow of Magdalene College, Cambridge.



Thomas Pridgin Teale.

The second Thomas Pridgin Teale, whose career we are now outlining, was educated at Leeds Grammar School, Winchester, and Brasenose College, Oxford, where he graduated in mathematics in 1852 without particular distinction. He then started as a medical student at King's College, London, and four years later became M.R.C.S. Eng., graduating in medicine simultaneously at his university. He immediately became connected with the Leeds School of Medicine, and for some 20 years lectured there on anatomy and surgery, being appointed surgeon to the Leeds General Infirmary in 1864 in succession to his father. This post also he held for 20 years, retiring from the active staff in 1884, when he was appointed honorary surgeon to the institution. To-day it would be impossible for any surgeon to obtain the position which Teale enjoyed as alike a great general surgeon and a recognised specialist along completely different scientific and technical lines. He was, perhaps, in the first place an ophthalmologist although he did not practise as an eye specialist. He was a pupil of Bowman, wrote considerably and valuably on diseases of the eye and the technique of their treatment, and introduced the suction curette for the extraction of cataract. He was also a great plastic surgeon, and devised ingenious means for remedying cicatricial disfigurements from cervical adenitis in tuberculosis. Teale and his distinguished colleague at the Leeds General Infirmary, Clifford Allbutt, made elaborate inquiry into this distressing condition, with the result that the removal of the glands by operation was inaugurated and found to give favourable cosmetic results. The third direction in which Teale made fruitful innovations in surgical practice was in connexion with vesicular and urethral surgery. In the last two departments of practice he followed his father in the same manner in which he had followed him in educational and staff appointments. In a similar way son followed father when the subject of this memoir became Crown representative upon the General Medical Council in 1876, a position which he occupied for no less than 25 years, being elected five consecutive times. It need hardly be said that in the decisions of the Council Teale consequently played a very valuable part, for he was equipped, both as an authority on medical education and as an expert in medical science, with the additional merit of long-continued service.

To all the public Teale was widely known as a sanitarian, for here he wrote for popular as well as for technical audiences. In the first instance the question of domestic sanitation, or rather insanitation, in relation to medical practice occupied his attention, and some time before bacteriology could lend any force to his teachings he attributed to bad drainage many epidemic and septicæmic conditions, and much of the mortality after surgical operations, whether performed in private or in institutions. As long ago as 1879 he wrote a popular work entitled "Dangers to Health," which formed a pictorial guide to domestic sanitary defects and achieved popularity in France, Spain, and especially Germany, having been translated into the German language by the late Princess Christian. Teale lectured on domestic sanitation in Leeds and other large cities, and there is no doubt that he created a very wholesome public desire to do away with the abuses revealed. Later, he concentrated on the subject of ventilation, and wrote "Dust and Fresh Air: How to Keep Out the One and Let In the Other," and devised a method of ventilation with Tobin's tubes which for a time enjoyed considerable popularity. He wrote also a pamphlet entitled "Economy of Coal in House Fires," and demonstrated his theories upon domestic fireplace construction by the invention of the well-known "Teale grate."

Teale, who was elected F.R.S. in 1888 and made an Hon. D.Sc. of the University of Leeds shortly afterwards, was twice married, first to Alice, daughter of the Rev. W. H. Teale, who died in 1891, and secondly to Jeanie, second daughter of the late Mr. D. C. Jones, of Tamworth, and leaves four daughters and four sons, one of whom carries on the medical tradition of the family.

A colleague writes: "Various causes contributed to the beneficent influence which Mr. Pridgin Teale exercised in Leeds, in Yorkshire, and wherever his work was felt. Before everything must be placed his personal character. Next should come his enthusiastic interest in his profession and in collateral sciences, though it is probable that only the older generations can remember his contributions to surgery, ophthalmic surgery, and sanitary science, because they are now merged in the ordinary teaching of those subjects. Then his unobtrusive and obviously disinterested efforts to promote the welfare of Leeds gained for him the regard of those leading citizens who recognised the importance and value of his help. And lastly, his Oxford training and associations played a part not very easy to estimate, but one that should not be omitted. The following anecdote will show how he stood in the estimation of his colleagues. Many years ago the writer of these notes was discussing with one of them the degree of eminence to which Mr. Teale would be judged to have attained. My friend, who at the moment was in a somewhat critical vein, after pondering over the various items of Teale's record, enunciated the following verdict: 'Yes, there is no doubt he is a good little man,' and it was Teale's goodness that gave the high value to his public work and scientific achievements. He was, as has been indicated, a man of small frame, and the delicate figure went with a thoughtful, intellectual face. In repose the latter wore an expression of gravity, but in conversation it would break into a singularly alert and happy smile. The possible extravagances of an enthusiastic temperament were kept in complete subjection by a judicial frame of mind. His principles when enunciated were firmly implanted in his nature, and in forming his opinion on any question submitted to his judgment the unselfish sincerity of the man was transparent. In debate or at the council board of the hospital he would express himself in measured, temperate terms without any signs of warmth or irritation, even when circumstances might have been some excuse for them.

Such a character could not fail to acquire the respect and affection of younger men as well as of contemporaries, and affectionate esteem was the predominant feature of the regard in which he was held by those who became his colleagues after his elevation to the consulting staff. They respected him for the good work which he had done before they knew him, for the wise counsel which he was always ready to give to such of them as sought him in difficult moments, and latterly for his venerable old age. Their affection was gained alike by the charm of his friendly manner and by the evident pleasure with which he followed any work they were doing, and the pride which he took in their successes. Nor did he ever, despite his advancing years, become merely a tradition to the students. Probably most of them have listened to one of his occasional addresses; and it is certain that those who have will always retain a pleasant memory of an unusually interesting occasion.

His influence upon professional conduct in Leeds was wholly for the good, for his fine ideals and firm grasp upon right principles guided any advice which he might give. He was never led to side with any of the various currents set in motion by gusts of professional politics, and probably of some of them he remained ignorant, but his choice as a Crown representative on the General Medical Council was justified thoroughly by his wisdom. Many practitioners will remember his characteristic letters to them about their cases, written often in the train with a blue pencil upon single sheets of blue notepaper. But I wonder if it is generally known what became of the practitioners' communications. When each answer was written, unless the letter was required to confirm any notes on the case, it was torn up into fragments and stuffed into a small silk bag for subsequent destruction. This may be thought to be faddy, but it was an evidence of the meticulous care which he took to prevent any possibility of abuse of professional confidence. And there is a circumstance which speaks volumes for the respect in which Teale was held by the profession outside Leeds. Men who have since risen to eminence, and indeed who were marked out for it at the time, sought to be his assistants for a period that they might see private practice under his auspices.

Teale showed his sporting instincts by becoming an enthusiastic fisherman, and like most devotees of that art could wax eloquent on the joys of hooking and landing a salmon. He saw no monotony in fishing day after day without success, and he once assured the writer that if a real fisherman caught one salmon it should make him happy for a fortnight."

PROF. D. W. FINLAY, M.D., LL.D.

IN our last issue we briefly announced the death of Emeritus Professor David White Finlay, who from 1891 to 1912 held the chair of medicine at Aberdeen University. Born in Glasgow in 1840, Prof. Finlay graduated B.A. and M.D. at Glasgow University. He later continued his studies in Vienna, and was subsequently appointed physician and lecturer at the Middlesex Hospital in London and physician to the Royal Hospital for Diseases of the Chest and the Royal Scottish Hospital. He also acted as inspector of examinations in medicine to the General Medical Council. After his appointment to a professorship in Aberdeen he had the honour of representing the University at the bicentenary celebrations at Yale University in 1900, and in 1907 he became dean of the faculty of medicine in succession to Prof. Robert Reid. Royal recognition of his ability as a physician was bestowed on Prof. Finlay in the following year, when King Edward VII. appointed him one of the Honorary Physicians to His Majesty in Scotland, and in June, 1911, a similar honour was conferred upon him by King George V.

Prof. Finlay had many interests outside his professional work. In addition to his authorship of many publications in the medical papers and the Transactions of various medical societies, he was a recognised authority on yachting, and published several important works on that subject. He was an LL.D. of both Yale and Aberdeen Universities, a Fellow of the Royal College of Physicians, London, and of the Royal Society of Edinburgh.

In appreciation of Prof. Finlay as a teacher a correspondent writes: "It is now practically 12 years since Prof. Finlay retired from the regius chair of medicine in the University of Aberdeen and the post of senior physician to the Aberdeen Royal Infirmary, after having served the University devotedly for 21 years. After this period it is natural that impressions of a teacher should have become somewhat blurred by the imprint of other personalities at whose feet one has sat; but certain features of Prof. Finlay's teaching are unforgettable. He was one of a notable band of teachers at Aberdeen—Ogston, Hamilton, MacWilliam, and Stephenson are names that instantly occur, and among these vigorous and differing personalities Prof. Finlay held a distinct place of his own. He was not, perhaps, so loved personally by his students as 'Old Howdie,' but 'Dauvit' undoubtedly left his mark on the succeeding years of men. Punctuality, accuracy of observation, and interest in detail are three features of his teaching which cannot be forgotten.

Prof. Finlay in his systematic teaching of a subject so wide as that of his chair, succeeded in giving the student a thorough grounding in the standard principles of medicine: and to his clinical teaching he brought a wealth of experience and a shrewdness of observation which did not fail to drive home the essential features of a case in a way not easily forgotten. Occasionally, too, there were flashes of a quiet dry humour, generally at the expense of some unfortunate student who showed some lack of precision in his examination or tried to evade a direct answer to a searching question. One got the feeling that even at 9 A.M. on a wintry Aberdeen morning it was of little avail for the sharpest witted young student to try to bluff the old professor at a clinic. Youth is apt to criticise old age as being naturally old-fashioned (and sometimes, alas! with a certain degree of justification), but Prof. Finlay as the years went on never grew senile in either mind or body, and no better grounding in fundamentals of systematic and clinical medicine and of sound treatment could have been got by the student.

Apart from his actual professional work, Dr. Finlay took an active part in the affairs of the University as a whole. He was also deeply interested in the social questions of the city. And beneath the quiet and almost reserved manner to his students he had a very living interest in their well being. For his work he had the highest ideals, and the impression his memory leaves is that of unswerving uprightness as a man, and of throughness, accuracy, and love of truth as a teacher."

CHARLES RICHARDSON, M.R.C.S. ENG.

THE death took place on Nov. 11th, at his residence in Leeds, of Dr. Charles Richardson, reputed to be the oldest medical practitioner in the city, both as regards age and length of professional services. Dr. Richardson was in his eighty-first year, and underwent some weeks ago a severe surgical operation. He became M.R.C.S. in 1867, and was at one time President of the Leeds and West Riding Medico-Chirurgical Society. He had an extensive practice in his own district in Leeds, where his well-set-up figure was familiar for half a century. Unselfish to a degree, he was beloved by all who knew him, and his breezy manner did much to inspire his patients with confidence. He was intimately associated with the Volunteers, being Surgeon-Major to the 2nd W.R. Yorks V.R.E. He was popular as a cricketer and lawn tennis player and as a member of the old Archery Club. Himself a non-smoker and a teetotaller, he was not censorious of the use by others of tobacco and alcohol. One of Dr. Richardson's two sons was killed in the war.

ALEXANDER E. GARROW, M.D., C.M. MCGILL.

THE death from heart disease is reported from Montreal on Nov. 7th of Dr. Alexander Garrow, well known as a surgeon throughout Eastern Canada. Of Scottish origin, he was the son of John Garrow, born in Ottawa in 1862, and educated there and at McGill University, where he graduated in 1889 as gold medallist. After practising for some time in Ottawa as partner of the late Dr. A. A. Henderson, he settled in Montreal, where he became Assistant Professor in Surgery and Clinical Surgery at McGill University and assistant surgeon to the Royal Victoria Hospital. In 1891 he married Miss Victoria Craig of North Gower, Ontario.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg.-Lt. (ret.) J. G. Stevens to be Surg. Lt.-Comdr. (ret.).

A. W. Ross and J. Hamilton to be Surg.-Lts.

Surg.-Comdrs. A. E. P. Cheesman to *Weymouth*, on completing, for passage out and home; and Surg. Lt.-Comdr. E. Hefferman to *Ganges*, for R.N. sick quarters.

ROYAL ARMY MEDICAL CORPS.

Capt. T. K. Boney retires, receiving a gratuity, and is granted the rank of Maj.

Lt. H. A. Gilkes resigns his commn.

MILITIA.

The undermentioned Capts. to be Majs.: T. Walker and W. McK. H. McCullagh.

TERRITORIAL ARMY.

Maj. E. W. Herrington having attained the age limit is retd. and retains the rank of Maj.

Maj. A. Ayre-Smith resigns his commn. and retains the rank of Maj., with permission to wear the prescribed uniform.

ROYAL AIR FORCE.

The undermentioned are granted permanent commissions: R. W. Ryan to be Squadron Leader; and E. C. K. H. Foreman and C. A. Lindup to be Flight Lts.

A SOUTH AFRICAN "MEDICAL" PRESCRIPTION.—At Dordrecht Circuit Court, Cape Province, S. Africa, a man named Henry Lawrence was recently charged with posing as a doctor under the name of Hendrik Hugo. Lawrence had lived in Basutoland and he had professed to treat a number of people and had received considerable sums of money (in one case over £60) from them. The "medicine" used seemed to be ordinary soil, though the accused maintained that it was a concoction of roots. The judge, in passing a sentence of three years' hard labour, described the case as the most extraordinary in his personal experience.

Correspondence.

"Audi alteram partem."

THE LONDON FEVER HOSPITAL.

To the Editor of The Lancet.

Sir,—You have given a kindly notice of the London Fever Hospital from the medical point of view. May I add a few words from the patient's side of the question?

A good many years ago I had an attack of scarlet fever. My doctor advised me to go to the London Fever Hospital, telling me I should get there the very best medical attendance and nursing. He was right. The visiting physicians at that time were Sir William Broadbent and Dr. Cayley, of Middlesex, and Dr. (later Sir) Shirley Murphy was the R.M.O. I found in them kind and pleasant friends, and our friendship lasted till they died. Like many other patients I got attached to the hospital and joined the committee. We have always had three or more ex-patients on the committee, and it is often convenient to have on a hospital committee men who know it from the inside as well as from the outside.

From the patient's point of view, a hospital has many advantages over even the best nursing home. You have eminent visiting physicians, and there is an R.M.O. always on the spot. If any emergency occurs the whole appliances of the hospital are ready to hand. The nurses are specially trained, and are under a reliable matron. The hospital is constructed for the comfort and convenience of the sick. For example, at the L.F.H. 22 of the private rooms open out on to balconies, so that patients can be moved out into the open air when the weather permits. There are many other advantages known to everyone who is acquainted with the inside of a good hospital.

I am, Sir, yours faithfully,

Nov. 19th, 1923. M. D. Chalmers.

ANNUAL MEETING OF THE FELLOWS AND MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To the Editor of The Lancet.

Sir,—Will you favour me with space to reply to the remarks of the President of the College at the close of the annual meeting on Nov. 15th? The Members had not an opportunity of answering then, and Sir John Bland-Sutton did not reply to the suggestions made nor to the points brought forward for the first time, save by reading a prepared statement. The President told us if we wanted a vote for the Council all that was necessary was to become Fellows and lauded the status of the College, its library, and museum. The mouse in the trap is not interested in being told of the excellent quality of the cheese that has attracted him. He is likely, if he can, to tell his own little mice and other mice outside not to follow him. The President appears to give all the credit to the Charter of 1843 for the high position of the College to-day, but one seems to have heard of great surgeons of the College before that date, and surely John Hunter deserves some credit for the fame of the museum. Is there not some evidence of myopic vision in the prospect and retrospect of the Council of the College?

The Member is the "foot" in the shoe, and he knows when and where it pinches. All he asks is that his "head" (the Council) should appreciate, and if possible, relieve his discomfort. That is not possible if the lines of communication—the nerves—between the "foot" and "head" are disconnected, as they are at present. There is no liaison officer between the Members and the Council—no way by which the Council can now get first-hand knowledge of the Members' views This is the essence of the Members' difficulty and claim. From the President's speech one would infer that the College is only concerned with the production, on eugenic lines, of a perfect surgical baby. When he is born his College leaves him on the (outer) steps for any chance foster-mother to protect—e.g., the B.M.A. This appears to be the College conception of parental responsibility. If such is the sole function of the College, why does it speak in the name of its 18,000 Members, without first ascertaining their views on matters of medical policy when consulted by the Government or other public bodies? The Council last year made a point that in conceding the Members' claim it would be acting at variance to the views of its electorate of 1700 Fellows. But the last occasion it consulted the Fellows on this question was in January, 1897.

The Society of Members sent a questionnaire post-card to the Fellows some months ago. The results are still coming in from abroad, but a surprisingly large number of Fellows courteously replied, and over 73 per cent. of the replies were in favour of the Members' claim. The Fellows were praised by the President for showing great interest in their College because less than two-thirds of them voted (by post) for the Council. While the Members were said to be apathetic because, though scattered over England and the Colonies, busy men in general practice, they did not come in larger numbers to the annual meeting to vote in person for their claim. Can it be wondered that they are not eager to come when the only result of their exertions is to receive from the Council a chilling *non possumus?* Is there logic, or fairness, or even a common denominator in this comparison? Would it not be more reasonable for the Council, if they have any real doubt as to the Members' views, to issue a questionnaire to them on the subject? If they would then meet representative Members round a table they could easily reach a solution, satisfactory to all, which would greatly strengthen the College and the diplomates.

I am, Sir, yours faithfully,
Redmond Roche,
President of the Society of Members of the Royal
Nov. 17th, 1923. College of Surgeons of England.

THE IMPORTANCE OF NASAL SINUS INFECTIONS.

To the Editor of The Lancet.

Sir,—The contributions of Dr. A. L. Yates on the Simulation of Pulmonary Tuberculosis by Painless Maxillary Sinusitis (The Lancet, Nov. 3rd), and of Dr. T. B. Jobson on Unsuspected Nasal Sinus Disease (Nov. 10th) are of immense practical value, and in each the thesis is advanced in a manner that convinces. I have myself urged the import of nasal sinusitis as a cause of symptoms so difficult to differentiate from those of pulmonary tuberculosis. Apart from exploration of the sinuses that a diagnosis of pulmonary tuberculosis without the tubercle bacillus being found should be accepted with caution and should always lead to the suspicion of a focal sepsis, while the almost equal import of sinusitis or indeed of any obstructive nasal defect co-existing with pulmonary tuberculosis was brought home to me 20 years ago by cases referred to me by Dr. Thurnam, of Nordrach-on-Mendip. Such nasal defects may neutralise all the advantages of sanatorium treatment. I would, however, venture to challenge Dr. Yates's statement that the larynx shows general redness and swelling of the posterior surface of the arytenoids when, and only when, the epiglottis is not tilted backwards, for while such evidence of laryngitis is not seldom present in nasal sinusitis, it is very often non-existent, and its occurrence or absence can hardly be attributable to the position of the epiglottis.

But both Dr. Yates and Dr. Jobson seem to me to attach too much value to the appearance of pus. Dr. Yates states that "frontal and anterior ethmoidal sinusitis do not complicate the diagnosis of chest conditions, because pain is always present in these conditions, and attention is early attracted to the nasal condition. Posterior ethmoidal and sphenoidal sinusitis have been met with in conjunction with infection of other sinuses, but not otherwise." These statements are incorrect, and their acceptance may lead to cases of sinusitis simulating or complicating phthisis being overlooked. Dr. Jobson, I suggest, attaches too much value to exploration of the maxillary antra by puncture and lavage, and depends for his diagnosis on the appearance of pus in the escaping fluid, but he affords no evidence of his explorations extending to the other sinuses, notwithstanding his early emphasis of the size and import of the sphenoidal sinuses. It is the value of these contributions and their indications of scientific progress in fields of work hitherto insufficiently explored that impels me to invite their further attention to the more exact methods of determining or excluding the existence of focal infection, especially in the ethmoidal cells and sphenoidal sinuses. Also I suggest confirming their diagnosis of maxillary antral and other sinus infections by histological and bacteriological investigations rather than taking the macroscopic appearance or absence of pus as their criterion of infection, otherwise reliance on imperfect though generally accepted methods may lead them to the error of excluding a diagnosis of sinus infection which nevertheless exists, mistakes that I am conscious of having frequently made myself until I adopted the method of exploring individual sinuses by the suction syringe and filming and culturing the sinus contents.

I am, Sir, yours faithfully,

P. WATSON-WILLIAMS, M.D. Lond.

Clifton, Bristol, Nov. 19th, 1923.

EPIDEMIC DIAPHRAGMATIC PARALYSIS.

To the Editor of THE LANCET.

SIR,—In view of the annotation on this subject in THE LANCET of Nov. 17th, it might be worth recording that there is an epidemic of a similar nature in this rural area. Since Oct. 30th 30 cases have come to my notice. The attack starts suddenly with painful respiration, or possibly pain in the epigastric or right hypochondriac regions, made worse by any movements. Slight fever (up to 101° F.) is generally present, also constipation and furred tongue. The pain generally lasts three days, having periods of greater or less intensity, and often passes into the right shoulder, neck, or lumbar region. After one day of complete ease the pain has recurred in one-third of the cases, with fever up to 101°, and in these cases has been present up to the seventh day. White blood counts were made in two cases which were suggestive of appendicular colic, but no leucocytosis was noted. There has been an absence of headache, sore-throat, coryza, nausea (except in one case), glandular enlargement, and prodromal symptoms. Infection would appear to be by contact, and three cases have suggested an incubation period of one week.

It would be of interest to hear if there has been any spread of this epidemic and if so the earliest date on which it was noted. I might add that cases have occurred in an area where there are two different water-supplies.—I am, Sir, yours faithfully,

Godalming, Nov. 18th, 1923. H. W. LEATHAM.

PRESENTATION TO SIR ALFRED RICE-OXLEY.—At Kensington Town-hall on Nov. 15th, in the presence of a large and representative gathering including many medical men, a presentation was made to Sir Alfred and Lady Rice-Oxley, ex-Mayor and Mayoress of Kensington, for the many valuable public services they had rendered to the Royal borough during Sir Alfred Rice-Oxley's three years' tenure of the office of Mayor. The Mayor, Councillor A. J. Allen, presided. The presentations, made by Lord Phillimore, consisted of, to Sir Alfred Rice-Oxley a portrait of himself, painted by Mr. W. W. Russell, A.R.A., and to Lady Rice-Oxley a handsome diamond pendant. Sir Alfred and Lady Rice-Oxley both replied. Sir Alfred Rice-Oxley then presented the portrait to the borough, so that it might hang in the town-hall with the portraits of other mayors, and himself retained the replica.

Parliamentary Intelligence.

HOUSE OF LORDS.

FRIDAY, NOV. 16TH.

Prorogation of Parliament.

THE Lord Chancellor, having read the King's Speech in His Majesty's name, prorogued Parliament to Thursday, Dec. 20th.

HOUSE OF COMMONS.

WEDNESDAY, NOV. 14TH.

Slum Clearances.

Mr. GILBERT asked the Minister of Health how many grants, and what was the total amount of the same, given by his department during 1922 and the present year for slum clearances; and what towns or areas the largest amount of this sum would be given.—Lord E. PERCY (Parliamentary Secretary to the Ministry of Health) replied: Eighty-six local authorities are undertaking, or have under consideration, schemes for the improvement of slum areas, and the annual Exchequer contribution towards the losses on these schemes will be approximately £127,000. The largest contributions will be made in the case of the London County Council, who contemplate schemes involving a total annual loss of £100,000, of which half will fall on the Exchequer. A number of these schemes have already been confirmed. Schemes of considerable magnitude are also proposed by a number of the more important county boroughs, notably Liverpool and Manchester.

Workmen's Compensation Bill.

The Workmen's Compensation (No. 2) Bill was read a third time. The Royal Assent was given to this measure on Friday, Nov. 16th, previous to the prorogation.

THURSDAY, NOV. 15TH.

Panel Doctors' Fees.

Lieut.-Colonel NALL asked the Minister of Health whether he had received an answer to the final offer made to the panel practitioners regarding their terms of service after Jan. 1st, and, if so, what action he proposed to take.—Sir W. JOYNSON-HICKS replied: Yes, Sir. My offer was accepted by a unanimous resolution of the Conference of Panel Committees held yesterday, the alternative being chosen of a Court of Inquiry to investigate and make recommendations as to the capitation fee properly payable as from Jan. 1st. I am taking steps to set up the court as quickly as possible. I understand that the resignations will be withdrawn.

Mr. RHYS DAVIES: Will the right hon. gentleman state where he is going to find the money to pay the increase from 7*s.* 3*d.* to 8*s.* 6*d.*? Will he consult the approved societies on this question and at once call together his own Consultative Council to find out what they think?—Sir W. JOYNSON-HICKS: The question whether anything will have to be paid to the doctors above 7*s.* 3*d.* is a matter for the Court of Inquiry. There is no need for me to consider finding any money until the court has arrived at a decision. I shall be perfectly prepared to call together my Consultative Council. I have been in communication with them yesterday and to-day, and wrote them a very long letter in reply to one which they sent to me this morning.

Sir KINGSLEY WOOD: Will it be open to any insured person to go before this Court of Inquiry and to give evidence as to the character of the panel service and to urge that far too much money has already been spent upon it?—Sir W. JOYNSON-HICKS: There are something like 14,000,000 insured persons, and if they all claimed the right to appear the inquiry would be impossible. In reply to Lieut.-Colonel POWNALL, we have arranged that the approved societies who represent to a very large extent the insured population will have the fullest rights to appear before the Court of Inquiry and state their views.

Colonel NALL: May I ask whether in the final consideration of this question the chief interest to be considered will be that of the insured persons?—Sir W. JOYNSON-HICKS: Certainly. The object I have had in all these long negotiations has been to get an adequate and proper medical service.

Replying to further questions by Mr. DAVIES, Sir KINGSLEY WOOD, and Sir J. BUTCHER, Sir W. JOYNSON-HICKS said that he had already dictated letters to three gentlemen whom he had asked to act as members of the Court of Inquiry. He was not in a position to announce the terms of the inquiry or the form of reference to be put before the court, but it would be a very simple one. It was not yet drafted, but he might say without binding himself to the exact terms that it would simply be to ask the Court of Inquiry to ascertain what was the correct figure to be paid to the doctors for the medical service which they rendered. It would be open to all parties to appear before the court.

European Death-rates.

Mr. RHYS DAVIES asked the Minister of Health to state the death-rate among adults, men and women separately, in each European country during the last four years, as compared with our own statistics, giving similar figures covering infantile mortality.—Sir W. JOYNSON-HICKS replied : I am not in a position to state the death-rates in these countries for adults only, or for men and women separately. The following table gives such information as is available as to the general death-rates (D.R.) and the infant mortality-rates (I.M.R.) for the four years 1918 to 1921. The figures for 1922 are not yet available.

Fees of Doctors and Midwives.

Mr. RHYS DAVIES asked the Minister of Health to state separately the charges or fees of doctors and midwives attending in confinement cases in working-class homes in the years 1911, 1912, 1913, 1922, and 1923, respectively.—Sir W. JOYNSON-HICKS replied : I have no information as to the charges made in these cases in the years 1911 to 1913. I understand that the fees of midwives now vary from 15*s.* to 30*s.* per case in rural areas, and from 1 guinea to 2 guineas in urban areas. These figures apply both to 1922 and 1923. I have no information as to the charges made by doctors attending these cases in their private practice, but when a doctor is called in by a midwife under Section 14 of the Midwives Act, 1918, he receives a fee of 2 guineas from the local supervising authority. The services rendered for this fee are specified in a circular issued by my department.

Cost of Pensions.

Mr. SHORT asked the Minister of Pensions the total cost of pensions as compared with 12 months ago.—Capt. CRAIG (Parliamentary Secretary to the Ministry of Pensions) replied : Excluding the cost of administration, the total expenditure of the Ministry for the year ending March 31st, 1923, was approximately £76,500,000, as compared with the estimated expenditure of £70,000,000 for the present financial year, a decrease of £6,500,000, or 8½ per cent. The cost of administration (including that of medical services) will, it is expected, have fallen from £4,241,600 for the year ending March 31st, 1923, to £3,598,000 for the current year, a decrease of over £640,000, or nearly 16 per cent.

Venereal Disease.

Capt. ARTHUR EVANS asked the Minister of Health whether Clause 16 of the Trevethin report, dealing with the expenditure of money for reducing venereal disease, had yet been considered by the Government ; whether the question of Government financial assistance to the work of voluntary organisations had been decided ; and whether, in view of the fact that the Society for the Prevention of Venereal Disease and the National Council for Combating Venereal Diseases had both unconditionally accepted the Trevethin report, and had met in conference and had determined on joint action for giving effect to its recommendations, he would cause the maximum grant, which was to be made by the Government, to be divided in an equitable proportion between the two organisations.—Sir W. JOYNSON-HICKS replied : The answer to the first two parts of the question is that the recommendations in the Trevethin report, including the question of financial assistance from the Exchequer to the work of voluntary organisations, are now under consideration by the Government. As regards the third part, I am not yet in a position to say how any Government grant for this purpose will be allocated.

Supplies of Calf Lymph.

Mr. BARKER asked the Minister of Health if he was aware that private medical practitioners were experiencing difficulty in obtaining supplies of glycerinated calf lymph of the same guaranteed purity as that supplied to public vaccinators by the Ministry of Health ; and would he take steps to see that such lymph was procurable at a reasonable charge by private medical practitioners from Government sources.—Sir W. JOYNSON-HICKS replied : As regards the first part of the question, I am advised that there is no difficulty in obtaining from reputable firms supplies of glycerinated calf lymph of reliable quality. The action suggested in the second part of the question would involve a large and costly extension of the present Government supply, for which, as at present advised, I see no need.

Fire at Highbury Hospital.

Mr. WILLIAM M. ADAMSON asked the Minister of Pensions whether the committee of inquiry had yet reported on the origin of the disastrous fire at Highbury Hospital ; when the report would be available for Members of the House and the public ; and what compensation had been awarded to the unfortunate sufferers and to the relatives of the two men who lost their lives.—Capt. CRAIG replied : The report was printed in September and is on sale. In the case of the two men who unhappily lost their lives, entitlement to pension on behalf of their dependents has been admitted on the same basis as if death had occurred on service. All necessary medical treatment and attention has been provided for those who were injured. Two of these are still under treatment, and I am glad to say they are progressing satisfactorily.

Insanity.

Mr. BARKER asked the Minister of Health if he had received a copy of a resolution passed in August last by the guardians of the Bedwellty Union deploring the growing increase of insanity, imbecility, and epilepsy, which had become a serious menace to the national health ; and would he take measures for the eradication of these diseases by means of research work for the causes, prevention, and possible cure by propaganda similar to that carried out for tuberculosis, syphilis, &c.—Sir W. JOYNSON-HICKS replied : I have received a copy of the resolution referred to. While I concur in the view that insanity seriously affects the national health, I would point out that the incidence of insanity is not increasing out of proportion to the growth of population. Research into the causes of mental disorder is recognised as one of the first essentials if the possibilities of prevention and cure are to be fully explored. The question of propaganda, however, in regard to mental disorder presents special difficulties which would require further consideration before I could make any promise in the matter.

State of Public Health.

Capt. AINSWORTH asked the Minister of Health whether from the latest official statistics he could indicate the present state of the public health ; and whether there was any abnormal sickness of any sort being dealt with under the National Health Insurance Fund.—Sir W. JOYNSON-HICKS replied : As regards the first part of the question, I would refer the hon. and gallant Member to the report of the Chief Medical Officer of the Ministry of Health on the state of public health, which was issued in September. As regards the second part, the figures at present available show a lower expenditure on sickness and disablement benefits in the first three-quarters of the present year than in the corresponding period of 1922, and the total expenditure on those benefits is within the actuarial estimate.

The Tuberculosis Order, 1914.

Mr. F. HALL asked the Minister of Health whether he had received resolutions from local authorities urging that the Tuberculosis Order of 1914, which was suspended during the war, should be put into operation without further delay ; and whether he proposed to take the action desired.—Major BARNSTON (Treasurer of the Household) replied : The reply to the first part is in the affirmative. My right hon. friend would explain, however, that the cost of putting into operation the Order in question is estimated at £80,000 from the Exchequer and about twice that sum from local authorities. In the present financial stringency the Ministry would not feel justified in reviving the Order in view of the small number of local authorities who have expressed their wish for its reimposition.

Medical News.

University of London.—At examinations held recently the following candidates were successful :—

Third (M.B., B.S.) Examination for Medical Degrees.

Honours.—Susanna M. Bernard (*e*), London Sch. of Med. for Women ; Joan O. Geldard (*d*), Univ. Coll. Hosp. ; David Krestin (*a*, *d*), London Hosp. ; David Levi (*d*), St. Mary's Hosp. ; Alan A. Moncrieff (*a*, *d*, University Medal), Middlesex Hosp. ; Andrew J. Morland (*a*), Univ. Coll. Hosp. ; Eileen M. Saxton (*e*), St. Mary's Hosp. ; Ernest F. Smith (*e*), St. Thomas's Hosp. ; and Selwyn E. Tanner (*a*), Univ. Coll. Hosp.

(*a*) Distinguished in Medicine. (*d*) Distinguished in Surgery. (*e*) Distinguished in Midwifery.

Pass.—Edith I. L. Abbott, Univ. Coll. Hosp. ; Kathleen Ardell, London Sch. of Med. for Women ; John V. Armstrong, St. Mary's Hosp. ; Jessie H. Baxter, Univ. Coll. Hosp. ; Davis E. Bedford, Middlesex Hosp. ; Anthony Blackstock, King's Coll. Hosp. ; Kathleen N. Blomfield, London Sch. of Med. for Women ; Hilda A. Bond, Univ. Coll. Hosp. ; Frank Brockington, King's Coll. Hosp. ; Ellinor M. Burnett, London Sch. of Med. for Women ; James C. Churcher, St. Thomas's Hosp. ; Ronald S. Coldrey, St. Bart.'s Hosp. ; Gladys M. Cox and Helen I. Davies, London Sch. of Med. for Women ; Mary L. Davies, St. Mary's Hosp. ; Winifred Ealand, London Sch. of Med. for Women ; Harold C. Edwards, King's Coll. Hosp. ; Guy W. Elkington, Guy's Hosp. ; Mary E. Fox, London Sch. of Med. for Women and St. Mary's Hosp. ; Arthur W. Gott, Leeds University ; Dorothy E. Gray, London Sch. of Med. for Women ; Margaret C. N. Hadley, London Hosp. ; Theodore Handel, King's Coll. Hosp. ; Gladys Hill, London Sch. of Med. for Women ; Lydia M. Houghton, Bristol University ; Laura M. Jacobs, London Sch. of Med. for Women and St. Mary's Hosp. ; Archibald L. P. Jeffery, St. Thomas's Hosp. ; Leslie M. Jennings, St. Bart.'s Hosp. ; Harry V. M. Jones, St. Thomas's Hosp. ; Percy T. Jones, Univ. Coll. Hosp. ; Georges Klionsky, St. Bart.'s Hosp. ; Colin P. Ledward, Univ. Coll. Hosp. ; Mary A. Leslie-Smith, St. Mary's Hosp. ; Dorothy N. L. Leverkus, London Sch. of Med. for Women ; John H. M. Lloyd and Desmond M. MacManus, Guy's Hosp. ; Caroline A. Meade and Margaret S. Mills, London Sch. of Med. for Women ; William E. M. Mitchell, St. Bart.'s Hosp. ; David C. Muir, Middlesex Hosp. ; Albert B. Nutt, Sheffield University ; Judith E. M. Ormerod, London Sch. of Med. for Women ; Beryl Palmer-Jones, Univ. Coll., Cardiff, and King's Coll. Hosp. ; Emily C. N. Paterson, King's Coll. Hosp. ; Thomas V. Pearce, St. Thomas's Hosp. ; Ruth W. Plimsoll, St. Mary's Hosp. ; Eric D. Pridie, Liverpool University ; Margaret A. Quine, King's Coll. Hosp. ; Walter M. Ramsden, Guy's Hosp. ; Isabella McDougall Robertson, London Sch. of Med. for Women and St. George's Hosp. ; Morris Robinson, Univ. Coll. Hosp. ; Olive M. Salmon, St. Mary's Hosp. ; Agnes B. Smith, King's Coll. Hosp. ; Edith E. Stephens and Ella M. Stratton, London Sch. of Med. for Women ; Ralph S. Swindell, London Hosp. ; Ida M. Tancock, London Sch. of Med. for Women ; Joseph Whitby, Middlesex Hosp. ; James de Silva Wijeyeratne, Univ. Coll. Hosp. ; Caroline I. Wright, Charing Cross Hosp. ; and Marguerite A. M. Xavier and Mildred M. E. Yate, London Sch. of Med. for Women.

The following students have passed in one of the two groups of subjects :—

Group I.—Muriel E. Binns and Hilda M. Cunnington, London Sch. of Med. for Women ; David J. Davies, Middlesex Hosp. ; Barbara J. Edwards, Birmingham University ; Lucy M. Elsom, King's Coll. Hosp. ; Walter S. Evans, Univ. Coll. Hosp. ; John W. Joule, St. Bart.'s Hosp. ; Duncan C. McIntosh and Kate Madders, Univ. Coll. Hosp. ; Grace H. Newell, London Sch. of Med. for Women ; Elizabeth M. Nicholson-Smith, King's Coll. Hosp. ; and Maurice L. Sutcliffe, Univ. Coll. Hosp.

Group II.—Doris K. Brown, London Sch. of Med. for Women ; Cecily D. Crosskey, Birmingham University ; Kenneth H. Deane, St. Bart.'s Hosp. ; Vincent P. De Zoysa, Ceylon Med. Coll. and Univ. Coll. Hosp. ; George F. Gibberd, Guy's Hosp. ; Stanley J. Golden, London Hosp. ; Rachel Halperin, Univ. Coll. Hosp. ; James R. Hamerton, St. Bart.'s Hosp. ; Aglionby D. Hepburn, St. Thomas's and Westminster Hosps. ; Gwynedd Hugh-Jones and Kathleen M. Hyslop, London Sch. of Med. for Women ; David J. Jones, St. Thomas's and Westminster Hosps. ; Ronald E. Lane, Guy's Hosp. ; Lewis O. Lindsay, London Hosp. ; Francis Louis, Harold J. Malkin, and Doris I. Mart, Univ. Coll. Hosp. ; Violet E. M. Mizen, London Sch. of Med. for Women ; George S. Morgan, St. Bart.'s Hosp. ; Richard M. Morris, London Hosp. ; John P. Peel, Leeds University ; Cyril S. C. Prance, St. Bart.'s Hosp. ; Phyllis M. Rex, St. Mary's Hosp. ; Harold N. Rose, St. Bart.'s Hosp. ; William H. Royal, Bristol University ; Marjorie Rushbrooke, Birmingham University ; Alan R. Rutnam, Middlesex Hosp. and Ceylon Med. Coll. ; Mary M. Sillito, London Sch. of Med. for Women; Dorothy M. Stewart, London Sch. of Med. for Women and St. Mary's Hosp. ; Doris M. Stone, London Sch. of Med. for Women ; William Thomas, London Hosp. ; Kathleen C. Vost, St. Mary's Hosp. ; Edward G. L. Walker, St. Thomas's Hosp. ; James A. Walker, St. Mary's Hosp. ; Joan F. Whitelock, Univ. Coll. Hosp. ; Emrys Williams, St. Thomas's Hosp. ; John G. Wilson, Westminster Hosp. ; Esther Wingate, London Sch. of Med. for Women ; and Edith V. Wood, London Hosp.

Society of Medical Officers of Health.—A meeting of the Naval, Military, and Air Force Hygiene Group of the Society will be held at 1, Upper Montague-street, Russell-square, W.C., on Nov. 30th, at 5 P.M., when Major-General W. W. O. Beveridge will deliver his presidential address. Any medical men who have served with His Majesty's Forces are invited to attend this meeting.

Fellowship of Medicine and Post-Graduate Medical Association.—A two weeks' intensive course will be held at the Hampstead General and North-West London Hospital, Haverstock-hill, N.W. 3, from Dec. 3rd to 15th. The course will occupy the whole of each day, and will consist of clinical demonstrations in the wards, out-patient department, &c., by the various members of the staff. Two special demonstrations will be given at the North-Western Fever Hospital, Lawn-road, Hampstead, N.W. 3, on the diagnosis and treatment of infectious fevers ; during the second week there will be four clinical demonstrations on neurological subjects at the Hospital for Epilepsy and Paralysis, Maida Vale. Dec. 11th will be devoted entirely to clinical demonstrations in the various departments of the Paddington Green Children's Hospital, W. 2. The fee for the course is 4 guineas. Copies of the syllabus, with full particulars, can be obtained from the secretary to the Fellowship of Medicine, 1, Wimpole-street, W. 1.

Royal College of Surgeons of England: Annual Meeting of Fellows and Members.—This meeting was held at the College on Nov. 15th. The attendance numbered between 40 and 50 and Sir John Bland-Sutton presided. On Dr. Wallis asking whether the number attending museum demonstrations could be published, and Dr. Collingwood asking what was the number of Fellows voting at the Council elections, the President, in reply, said that the numbers attending museum demonstrations would be published again as they had previously, while the number of Fellows voting at the Council elections was included in the report of the College. Dr. S. C. Lawrence, the secretary to the Society of Members of the College, decided not to put the questions standing in his name, to which publicity had already been given.

The first resolution was then proposed by Dr. Edwin H. T. Nash in the following words :—

> That this thirty-fifth annual meeting of Fellows and Members again affirms the desirability of admitting Members to direct representation upon the Council of the College, which (as now constituted) only represents those Members who also hold the Fellowship ; and that it does so, in order that the constitution of the Council of the Royal College of Surgeons of England shall be in keeping with modern ideas of true representation ; further, that as the Royal College of Surgeons is composed of about 18,000 persons, of whom over 16,000 are engaged in general practice, this annual meeting requests the President and Council to consider some means whereby Members in bona fide general practice may be represented upon the Council of the College.

Dr. Nash suggested as an alternative, which was not accepted, that there should be a conference of the Council and representatives of the Society. The resolution was seconded by Dr. Redmond Roche, the President of the Society of Members of the College, who called attention to the disabilities of the Members, adding that the removal of non-registrable degrees from the Register had recently penalised practitioners in the public eye. He directed his remarks chiefly to the reasons given by the late President of the College for not acceding to the Members' claims, and with regard to the view of the Fellows he added that the Council had not tested that view for 27 years, while a questionnaire sent out by the Society had received favourable response. He alluded to the fact that this was the centenary of The Lancet, whose founder had carried his energetic protests against the management of the College in those days to a point at which Bow-street runners had to be called in to remove him from the precincts in which they stood. Dr. Vinrace, Dr. F. G. Lloyd, and others having spoken, the resolution was passed unanimously.

The second resolution, moved by Dr. H. M. Stratford and seconded by Dr. Charles Hayward, invited the President to state what in the opinion of the Council were the difficulties which prevented assent to representation on the Council of Members in general practice. Dr. Alexander Scott, Dr. Harrison, and Dr. Collingwood having spoken, the President, reading his reply, expressed his belief that the grievance of the Members could not be widely felt, or so many young men and women would not show keenness to obtain the diploma of the College, while it was open to any Member to become a Fellow by passing the required examination. He pointed out to the meeting that Fellows of the College who were in general practice had served on the Council and that part at least of the movement for a change of the constitution of the College was due to a misapprehension of the functions of the College. The meeting, which was conducted in an amicable spirit, closed with a vote of thanks to the President.

Society of Apothecaries of London. — The livery dinner will be held in the Apothecaries' Hall, Blackfriars, London, E.C., at 6.30 P.M., on Tuesday, Dec. 4th.

Small-pox in England and Wales.—During the week ended Nov. 10th 25 cases of small-pox were notified to the sanitary authorities of the following areas: Derbyshire 3 (Ripley 1, Blackwell R.D. 2); Durham 1 (Washington); Gloucestershire 10 (Gloucester 3, East Dean 7); Notts 8 (Hucknall); Yorks W. Riding 3 (Adwick-le-Street).

Manchester Radium Institute.—Owing to the increasing number of patients applying for treatment the executive committee has decided to expend £3000 in the purchase of more radium, which will bring the total sum expended on radium by the Institute to £40,000.

Royal Society of Medicine.—On Nov. 27th, at 5.30 P.M., a combined meeting of the Medical and Surgical Sections will be held in the Barnes Hall, 1, Wimpole-street, W. 1, to discuss the Surgical Treatment of Pulmonary Tuberculosis. The discussion will be opened by Prof. P. Bull, of Christiania, who is making a special visit to this country for the purpose of this meeting. All medical men and women interested in the subject are cordially invited to attend.

International Society of Applied Psychology in Paris.—The annual reunion of the Society was held on Nov. 20th, at 49 Rue Saint-André-des-Arts, under the presidency of Dr. Ch. Fiessinger. The subjects dealt with were: (1) The relation of affectivity to psychic diseases; (2) psychotherapy of troubles of affectivity; (3) individual communications on psychotherapy and applied psychology. Dr. C. Sampson (London) read a paper on Muscular Amnesia.

University of Manchester.—The following have been elected to Honorary Research Fellowships: Mr. E. D'Arcy McCrea, M.D., F.R.C.S.I., D.P.H., in physiology (for a second year), Mrs. Gertrude Robinson, M.Sc., in chemistry, and Mr. W. K. Slater, M.Sc., in chemical physiology (for a second year). Prof. A. V. Hill has presented to the University a sum of £300 to endow a prize to be awarded for an essay on a biochemical subject.

Presentation to Sir Frederick Mott.—On his retirement from the appointment of Pathologist to the London County Mental Hospitals (1895–1923) and Director of the Laboratory at the Maudsley Hospital, Sir Frederick Mott was the recipient of a presentation from his colleagues and co-workers. The presentation, which took the form of a Chippendale bookcase, was made at the London County Hall on Nov. 15th by Mr. H. F. Keene, chief officer of the Mental Hospitals Committee, Dr. P. C. Spark, senior medical superintendent, and Dr. Herbert Bond, Commissioner of the Board of Control. An illuminated book which contained 96 names set out the presentation "as a token of their appreciation of your brilliant research work, of your efforts in connexion with the establishment of the Maudsley Hospital, and of the great assistance you have afforded to workers in the field of psychological medicine." Sir Frederick Mott remains director of the course of psychological medicine at the Maudsley Hospital, where he is still working in the laboratory. His appointment as hon. director of the Birmingham Research Board was announced not long ago.

A New Ministries' Bill in Ireland.—Our Irish correspondent writes: A Bill is at present under discussion in the Irish Parliament for the grouping of the several departments of government under the appropriate ministries. Instead of the old local government department we are to have in future a ministry of local government and public health. This ministry will have control of activities approximately similar to those controlled in England by the Ministry of Health. In it will be the Local Government Department, the National Health Insurance Commission, the office of the Inspector of Lunatics, and the Registrar-General. All these are closely connected with the care of health. The Ministry unfortunately, however, is to perform other functions which bear no relation to health. Not content with the control already exercised by the Local Government Department over fairs and markets, it is to take over the care of roads from the Ministry of Industry. It is a distinct advance that the words "Public Health" should appear in the title of the Minister responsible for the public health, for it emphasises the importance of this part of his duties, both to him and to the public. Again, while it is satisfactory to leave the various activities concerned with health concentrated in one Ministry, it is unfortunate that that Ministry should be distracted by affairs not concerned with health. It is somewhat amusing that the Irish Public Health Council—the body founded to advise the Chief Secretary in his capacity as Minister of Health for Ireland—has been forgotten altogether in this fresh grouping of departments.

Sanitary Inspectors Examination Board.—The Board have appointed Dr. A. T. Nankivell (M.O.H., Hornsey), Dr. James Fenton (M.O.H., Kensington), Mr. C. G. E. Fletcher (Town Clerk, Islington), and Mr. Arthur J. Martin, M.Inst.C.E., to act as examiners for the Board during the year 1924.

Royal College of Physicians of Edinburgh.—At a quarterly meeting of the College held on Nov. 6th, with Sir Robert Philip, the President, in the chair, Dr. John Lindsay Boyd was elected a Fellow of the College, and Drs. W. Macrae Taylor, Robert A. Chambers, Atholl Robertson, and J. Primrose Leckie were elected Members of the College. The Hill Pattison-Struthers Bursary in Clinical Medicine was awarded to Dr. Edward R. C. Walker, the Hill Pattison-Struthers Bursary in Anatomy and Physiology to Mr. T. Duncan Gould, and the Wood Bursary to Mr. Ian A. G. L. Dick. Dr. Alexander Blackhall-Morison presented to the College a portrait of the late Sir Alexander Morison, and a baculum for the use of the Morison lecturer.

Hospital Finance in London, Liverpool, and Manchester.—In a communication to the *Manchester Guardian* of Nov. 16th Mr. F. G. D'Aeth, secretary of the Liverpool Council of Voluntary Aid, gives the following statistics showing the comparative sources of income from three large centres of population. The figures are for 113 London, 16 Liverpool, and 17 Manchester hospitals for 1922, and are based as follows:—London: All income received from the general funds of the hospitals, with the exception of the special appeal (£243,115). Liverpool: All money received during the year by the institutions as a whole (that is, general and smaller funds). The income thus includes all legacies and donations for investment. Manchester: All income received for general and special funds during the year, but excluding legacies for specific purposes and donations for investment. In each case the grants from the Voluntary Hospitals Commission are included in the figures—that is, London £146,200, Liverpool £10,964, and Manchester £12,485.

	London.	Liverpool.	Manchester

The Lancaster Medical Book-Club.—A dinner was given on Nov. 14th in celebration of the hundredth anniversary of the foundation of the club on Nov. 11th, 1823, about 90 members and guests being present. Mr. A. S. Barling, the President, was in the chair, and was supported by Sir Norval Helme, Prof. A. C. Seward, F.R.S., Mr. J. E. Singleton, K.C., Mr. E. W. Wingate-Saul, K.C., Canon Coates, and Dean Blundell. The original minute book was shown containing the resolution forming the club: "It is expedient to establish a society to be called the Lancaster Medical Book-Club, to consist of the gentlemen present and such other medical gentlemen resident in Lancaster as shall hereafter be elected by a majority of existing members." After the loyal toasts, Dr. W. H. Coupland proposed "The Guests," emphasising the importance of the influence of mind over matter and advocating the collaboration of the spiritual and bodily advisers. Whilst paying tribute to the research workers we must, he said, look to the general practitioner for warning of the earliest signs of disease. Mr. Singleton and Dean Blundell replied. Prof. Seward, in proposing "The Club," dealt with the relation of pure science to medicine which he described as an applied science. Every medical man ought to have a thorough grounding in science, and particularly in bio-chemistry and bio-physics. They ought to study the beginnings of life in its lowest forms. The President, in reply, gave a short history of the club which, although it retained its original name, had for more than half a century, if not from the first, been a clinical and ethical society. He epitomised medical progress since its establishment, remarking that so long as tubercle and cancer were unconquered the profession had little cause for self-admiration. All the wise men of the world had but touched the fringe of the hem of the mantle of knowledge. To take a leaf from the old minute of 1827: "The evening was spent in the greatest harmony and good order, and the company separated about 12 o'clock."

SOCIETY FOR CONSTRUCTIVE BIRTH CONTROL.—A dinner will be given to Dr. Marie Stopes at the Hotel Cecil, London, on Tuesday, Nov. 27th, at 7.30 P.M., Sir Arbuthnot Lane presiding.

CHADWICK PUBLIC LECTURES.—In consequence of the General Election the lectures by Major Harry Barnes and Dr. A. K. Chalmers are being postponed until the New Year.

ROYAL UNITED HOSPITAL, BATH.—At the conclusion of the second series of post-graduate demonstrations held at the hospital on Saturday afternoons from Oct. 6th to Nov. 10th, the class, which comprised some 40 practitioners, chiefly from the surrounding country towns, entertained the staff to lunch and presented them with a cheque for £50 for the museum fund.

ROYAL SOCIETY OF ARTS.—A lecture will be delivered on the Effect of Sun, Sea, and Open-air in the Treatment of Disease, by Sir Henry Gauvain, medical superintendent of the Lord Mayor Treloar Cripples' Hospital, on Wednesday, Nov. 28th, at 8 P.M., in the Society's premises at John-street, Adelphi, London, W.C. Lord Dawson will preside.

THE PARLIAMENTARY ELECTION:

MEDICAL CANDIDATES.

NOMINATIONS for the General Election which takes place on Dec. 6th must be made on or before Nov. 26th, and the new Parliament will assemble on Jan. 8th. The list of medical men who sat in the recent House of Commons is as follows:—

Late Member.	*Constituency.*	*Party.*
Sir George Berry	Scottish Universities	Conservative.
Dr. W. A. Chapple	Dumfries	Liberal.
Sir John Collie	Glasgow, Partick	National Lib.
Capt. W. E. Elliot	Lanark, Lanark	Conservative.
Dr. F. E. Fremantle	Hertford, Albans	Conservative.
Dr. L. G. S. Molloy	Blackpool	Conservative.
Dr. J. E. Molson	Lincoln, Gainsborough	Conservative.
Sir Sydney Russell-Wells	London University	Conservative.
Dr. Alfred Salter	Bermondsey, West	Labour.
Dr. Thomas Watts	Manchester, Withington	Conservative.
Sir William Whitla	Queen's University, Belfast	Conservative.
Dr. J. H. Williams	Carmarthen, Llanelly	Labour.

Most of these have, we understand, signified their intention of standing again for their old constituencies. Sir John Collie and Dr. Molloy are not seeking re-election.

In addition the names of the following medical men and women have been announced as Parliamentary candidates:—

Candidate.	*Constituency.*	*Party.*
Dr. Ethel Bentham*	Islington, East	Labour.
Dr. R. Dunstan*	Birmingham, Ladywood	Labour.
Dr. M. I. Finucane	Westminster, Abbey	Liberal.
Dr. O. Gleeson	Portsmouth, North	Labour.
Dr. L. Haden Guest*	Southwark, North	Labour.
Mr. Somerville Hastings*	Reading	Labour.
Dr. G. B. Hillman	Yorks W.R., Normanton	Conservative.
Dr. H. B. Morgan*	Camberwell, North-West	Labour.
Dr. R. W. Simpson*	Newcastle-on-Tyne, North	Liberal.
Dr. E. G. Spero*	Stoke Newington	Liberal.
Dr. R. McNair Wilson*	Essex, Saffron Walden	Liberal.

An asterisk is affixed to the names of those who contested seats unsuccessfully at the General Election last year, the identical seat in each case with the exception of Mr. Hastings, who then stood for Surrey, Epsom, and Dr. Spero for Leicester, West.

The Parliamentary Elections Committee of the British Medical Association (429, Strand, London, W.C. 2) is no doubt supporting two or more candidates as at the last election, although we regret to note that Dr. H. B. Brackenbury is not standing again. The Federation of Medical and Allied Services (12, Stratford-place, London, W. 1) is also supporting medical candidates as on previous occasions and has already received several applications from such.

We may express a hope that medicine will be well represented in a House of Commons where social legislation is promised by each of the political parties.

THE SIMMINS APPEAL FUND.

THE third list of subscriptions, which we give below, brings the Fund appealed for on behalf of the children of the late Temp. Surgeon-Lieut. Alfred George Simmins to the gratifying total of over £1260. The first and second lists were published respectively in THE LANCET of April 21st and of June 2nd.

Third List of Contributions.

	£	s.	d.
Anon. (per Prof. T. B. Johnston, Guy's Hosp. Med. School)	21	0	0
Some Members of "Lloyds"	15	0	0
Members of the B.M.A. and other practitioners of Warrington (per J. B. Naden)	12	15	0

Anon. (per J. Curtis), J. C. Baker ..each	2	0	0
Drs. Rogers and Bell	1	11	6
A. E. Druitt	1	10	0
Anon., T. C. Blackwell, R. L. Crabb, Hubert Daw, J. S. Dudding, D. G. Greenfield, G. B. Good, G. W. Heckels, J. G. Jones, G. M. Kendall, H. A. Kisch, Dr. Lightwood, P. E. W. MacAdam, A. D. Marston, A. T. Scott, H. Steinbach, D. Tilbury, S.W. ..each	1	1	0
Francis Chown, A. B. de Freitas, Mrs. Sandiford each	1	0	0
Amounts under £1 total	2	0	0

The Fund Committee has recently met in order to discuss how the money shall be administered. It is now intended to close the Fund, but any members of the profession who may wish to subscribe and have not yet done so may send their contributions to the treasurer, Simmins Appeal Fund, at the Royal Northern Hospital, Holloway-road, London, N. 7.

Appointments.

FRESHWATER, D. H., M.D. Camb., M.R.C.P. Lond., has been appointed Assistant Physician to the Skin Dept., St. George's Hospital, S.W.

HENRIQUES, STELLA, M.B., Ch.B. Aberd., Assistant School Medical Officer to the Tillingham (Kent) Education Authority.

McCURRACH, ELIZABETH, M.B., C.M. Aberd., D.P.H., Surgeon to Nyasaland Church of Scotland Mission.

REID, J., L.R.C.P. & S. Edin., Assistant Medical Officer to the County Mental Hospital, Hereford.

WILSON, A. S., M.B., Ch.B. Glasg., Medical Referee under the Workmen's Compensation Act for County Court Circuit No. 6.

Surgeons under the Factory and Workshop Acts: **FOWWEATHER, F. S.**, M.B., Ch.B. Liverp. (Ellesmere Port District); **BARKER, G. L.**, L.R.C.P. Lond., M.R.C.S. (Wainfleet); **MARTIN, J. F. G.**, (Littleport).

Vacancies.

For further information refer to the advertisement columns.

Birmingham City Hospital for Infectious Diseases, Little Bromwich.—Sen. Asst. M.O. £350.

Brighton County Borough Mental Hospital, Hayward's Heath,—First Asst. M.O. £700.

Bristol City Mental Hospital.—Med. Supt. 1000.

Canterbury, Kent County Mental Hospital, Chartham.—Asst. M.O. £350.
Cardiff Royal Infirmary.—H.S. and Cas. Surg. O. £100.
Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Res. H.S. £75.
City of London and East London Dispensary, 40, Wilson-street, Finsbury, E.C.—Additional M.O.
Edinburgh Royal Infirmary.—Supt. £700.
Federated Malay States Hospitals.—Radiologist. £840.
Grimsby and District Hospital.—Jun. H.S. £125.
Hampstead General and North-West London Hospital, Haverstock-hill, N.W.—H.P., H.S., Cas. M.O. and Cas. S.O. Each £100.
Hampstead, Parish of St. John, New End Hospital.—Sen. and Jun. Res. Asst. M.O.'s. £250 and £150 respectively.
Hospital for Sick Children, Great Ormond-street, W.C.—H.S. and H.P. £50.
Huddersfield, Bradley Wood Sanatorium, &c.—Res. M.O. £500.
King's College Hospital.—Out-patient P., &c.
Lincoln County Hospital.—Sen. H.S. £250.
London Temperance Hospital, Hampstead-road, N.W.—Cas. O. £150.
Manchester Royal Infirmary.—Asst. Res. Surg. O. £200.
Metropolitan Hospital, Kingsland-road, E.—Asst. P.
National Hospital for the Paralysed and Epileptic, Queen-square, W.C.—Asst. P.
Oxford, Radcliffe Infirmary and County Hospital.—Res. Accoucheur. £120.
Prince of Wales's General Hospital, Tottenham, N.—H.S. £150.
Queen Mary's Hospital for the East End, Stratford, E.—Res. M.O. and Res. Obstet. S.
Rochester, St. Bartholomew's Hospital.—H.P. £200.
Royal Free Hospital, Gray's Inn-road, W.C.—Med. Reg., Surg. Reg., and Gyn. Reg. Each £250. Cas. O. £100. H.S. (M.M.S.) and Obstet. Asst. £50 each. Also H.P., H.S., Asst. Cas. O., and Obstet. H.S.
Royal London Ophthalmic Hospital.—Six Refraction Assts. £50 each.
Royal National Orthopædic Hospital, 234, Great Portland-street, W.—Hon. P.
Royal Northern Hospital, Holloway, N.—Asst. Radiologist. £150. Also Phys.
Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—H.P. and H.S. Each £100.
Sheffield Royal Hospital.—Asst. Cas. O. £100.
Union of South Africa Govt.—Asst. P.'s. £460.
Victoria Hospital for Children, Tite-street, Chelsea, S.W.—Dent. S.
Western Ophthalmic Hospital, Marylebone-road, N.W.—Hon. Asst. S. 100 guineas.
West London Hospital, Hammersmith-road, W.—H.P., H.S., Aural H.S. and Res. Cas. O. Each £100.
Windsor, King Edward VII. Hospital.—Jun. H.S. £140.

The Chief Inspector of Factories, Home Office, London, S.W., announces vacant appointments at Osmotherley (Yorks, North Riding), Long Sutton (Lincs), Sedbergh (Yorks, West Riding), and Redcar (Yorks, North Riding).

Births, Marriages, and Deaths.

BIRTHS.

Blair.—On Nov. 10th, at Westwood, The Park, Hull, the wife of R. Bertram Blair, M.B., F.R.C.S. Edin., of a son.
Clarke.—On Nov. 13th, at Baldwyn's Park, Bexley, the wife of Geoffrey Clarke, M.D., of a daughter.
Norman.—On Nov. 8th, at Kasauli, India, the wife of Brevet-Colonel H. H. Norman, C.B.E., R.A.M.C., of a daughter.
Peebles Brown.—On Nov. 12th, at Arncliffe, Malton, Yorkshire, the wife of Dr. D. Peebles Brown, of a daughter.
Watson.—On Nov. 16th, at Parkside, Reigate, the wife of Lieut.-Colonel J. W. Watson, I.M.S., C.I.E., Ajmer, Rajputana, of a daughter.
Woodhouse.—On Nov. 9th, at The Shrublands, Croydon, the wife of S. C. Woodhouse, M.B., M.R.C.S., of a daughter.

MARRIAGES.

Lawrence—Sandell.—On Nov. 20th, 1923, at the Church of St. Ambrose, Bournemouth, Sidney C. Lawrence, M.B., Ch.B. Birm., M.R.C.S. Eng., L.R.C.P., D.P.H. Lond., to Miss E. M. Sandell, of Devizes and Bournemouth.

DEATHS.

Beatty.—On Nov. 8th, at his residence, Merrion-square, Dublin, Wallace Beatty, M.D., F.R.C.P.I., aged 70 years.
Brookhouse.—On August 20th, at his residence, Ashby House, Tweedy-road, Bromley, Kent, Charles Turing Brookhouse, M.D., J.P., aged 76. (Delayed notice.)
James.—On Nov. 15th, at Chichester, George Thomas Brooksbank James, F.R.C.S., aged 56.
Jones.—On Nov. 16th, at The Willows, Stanford Dingley, near Reading, John Hervey Jones, M.D. London, M.R.C.S., L.R.C.P., B.Sc., aged 62. No flowers by request.
Love.—On Nov. 18th, at Upper Grosvenor-road, Tunbridge Wells, Dr. J. Duncan Love, late of Monkseaton, aged 54 years.
Teale.—On Nov. 13th, at North Grange, Headingley, Leeds, Thomas Pridgin Teale, in his 93rd year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, Nov. 26th.

ODONTOLOGY: at 8 P.M.
Casual Communications:
Mr. A. T. Pitts: (1) ? Dermoid Cyst of Mandible; (2) Dentigerous Cyst apparently arising from a Supernumerary Tooth.
Discussion:
On Pyorrhœa, its Prevention and Treatment. To be opened by Mr. J. G. Turner.

Tuesday, Nov. 27th.

GENERAL MEETING OF FELLOWS: at 5 P.M.
Ballot for election to the Fellowship. (Names already circulated.)

MEDICINE AND SURGERY: at 5.30 P.M. and 8.45 P.M.
Joint Discussion:
On the Surgical Treatment of Pulmonary Tuberculosis. To be opened by Prof. P. Bull (Christiania) and Dr. Clive Riviere, followed by Mr. H. Morriston Davies, Dr. E. Beaumont, Mr. J. E. H. Roberts, Dr. S. Vere Pearson, Dr. L. S. T. Burrell, and Dr. F. G. Chandler.
Dr. Stanley Melville will show X ray photographs.

Wednesday, Nov. 28th.

COMPARATIVE MEDICINE: at 5 P.M.
Paper:
Dr. S. G. Billington: Some Unusual Methods of Culturing the Blood, with special reference to Distemper. (With lantern and microscopical slides.)

Thursday, Nov. 29th.

BALNEOLOGY AND CLIMATOLOGY: at 5 P.M.
Discussion:
On Diuresis. To be opened by the President, Dr. Charles W. Buckley
Members of the Section will dine together after the meeting (at 7.30 P.M.) at the Boulogne Restaurant, 27, Gerrard-street, Wardour-street, W. 1. Price of dinner, 10s. 6d. Those intending to dine are asked to notify the Hon. Secretary (Dr. C. F. Sonntag) not later than Monday, November 26th.

MEDICINE, THERAPEUTICS, AND PHARMACOLOGY.
Members of these Sections are cordially invited to attend and to take part in this discussion.

UROLOGY: at 8.30 P.M.
Paper:
Mr. J. Swift Joly: The Mechanism of Prostatic Retention.

Friday, Nov. 30th.

BALNEOLOGY AND CLIMATOLOGY.
The arrangements for this meeting will be announced.

Saturday, Dec. 1st.

ANÆSTHETICS: at the Medical Institute, Edmund-street, Birmingham, at 4.45 P.M.
Papers:
Dr. K. B. Pinson: The Condensation of Di-methyl Ether and its Use as an Anæsthetic Agent.
Mr. Leonard Gamgee: A Surgeon's Thoughts on Anæsthesia.
Mr. L. Kirkby Thomas will show Dr. Dott's apparatus for endotracheal anæsthesia.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W. 1.
Monday, Nov. 26th.—8.30 P.M., Discussion on the Treatment of Acute Suppurative General Peritonitis. To be introduced by Mr. Sampson Handley, and followed by Mr. James Berry, Sir Cuthbert Wallace, Mr. Garnett Wright, Mr. H. W. Carson, Mr. R. P. Rowlands, Mr. V. Z. Cope, Dr. H. H. Rayner, Mr. T. H. C. Benians, and others.

LONDON DERMATOLOGICAL SOCIETY, 49, Leicester-square, W.C.
Friday, Nov. 23rd.—4.30 P.M., (1) Clinical Cases; (2) Pathological Specimens. 5.15 P.M., Dr. A. Knyvett Gordon: The Clinical Value of Certain Pathological Tests in Dermatology.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.
Wednesday, Nov. 28th.—8 P.M., Sir Henry John Gauvain: The Effect of Sun, Sea, and Open-air in the Treatment of Disease.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE, 1, Wimpole-street, W.
Monday, Nov. 26th, to Thursday, Nov. 29th.—Lectures at Chelsea Hospital for Women, London Lock Hospital, Maudsley Hospital, Royal Westminster Ophthalmic Hospital, and the Western General Dispensary (Children's Clinic).

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.
Monday, Nov. 26th.—10 A.M., Mr. Maingot: Surgical Pathology. 12 noon, Mr. Simmonds: Applied Anatomy. 3 P.M., Mr. Simson: Diseases of Women.
Tuesday.—10.30 A.M., Dr. Paterson: Medical Wards. 12 noon, Dr. Burrell: Chest Cases. 2.30 P.M., Mr. Tyrrell Gray: Surgical Wards.

WEDNESDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 12.15 P.M., Dr. Burnford: Medical Pathology. 3 P.M., Dr. Pernet: Skin Dept.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 11 A.M., Mr. Simson: Gynæcological Demonstration. 2 P.M., Mr. MacDonald: Genito-Urinary Dept.

FRIDAY.—10 A.M., Dr. Drummond Robinson: Gynæcological Operations and Wards. 2 P.M., Mr. Banks-Davis: Throat, Nose, and Ear Dept. 2 P.M., Mr. Sinclair: Surgical Out-patients.

SATURDAY, Dec. 1st.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: OCTOBER–NOVEMBER, 1923.

CLINICAL LECTURES AND DEMONSTRATIONS.

MONDAY, Nov. 26th.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., Optic Atrophy: Mr. Leslie Paton.

TUESDAY, Nov. 27th.—2 P.M., Out-patient Clinic: Dr. Grainger Stewart. 3.30 P.M., Tumours of the Spinal Cord: Mr. Armour.

THURSDAY, Nov. 29th.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Demonstration of X Ray Photographs: Dr. Russell Reynolds.

FRIDAY, Nov. 30th.—2 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Demonstrations of Physical Exercises in Exercise Room.

COURSE OF LECTURES AND DEMONSTRATIONS ON NEURO-PATHOLOGY.

MONDAY, Nov. 26th.—12 noon, Reactionary Changes in Central Nervous System, II.: Dr. J. Godwin Greenfield.

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M., or at such other times as may be announced.

Any part of the Course may be taken separately. Fees should be paid to the Secretary of the Hospital at the Office on entering for the Course.

Dr. J. GODWIN GREENFIELD, Dean of Medical School.

UNIVERSITY COLLEGE HOSPITAL.

WEDNESDAY, Nov. 28th.—5 P.M., Dr. Charles Singer: Early Medical Books.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.

THURSDAY, Nov. 29th.—5 P.M., Mr. T. B. Davies: Diagnosis and Treatment of Antepartum Hæmorrhage.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, Nov. 29th.—4 P.M., Dr. Frew: Enuresis.

ST. JOHN'S HOSPITAL, 49, Leicester-square, W.C.

TUESDAY, Nov. 27th.—5 P.M., Dr. J. M. H. MacLeod: Leprosy.

THURSDAY.—5 P.M., Dr. W. Griffith: Erythemato-squamous Dermatoses.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.

WEDNESDAY, Nov. 28th.—4 P.M., Dr. Kate Platt: Problems in Relation to Health in the Tropics.

THE PEOPLE'S LEAGUE OF HEALTH, 12, Stratford-place, Oxford-street, W.

Eight Lectures on the Mind and What We Ought to Know About It, at Hamilton House, Mabledon-place, W.C.

WEDNESDAY, Nov. 28th.—6 P.M., Fifth Lecture, Sir Robert Armstrong-Jones: Fatigue and Sleep.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION, 11, Chandos-street, Cavendish-square, W. 1.

THURSDAY, Nov. 29th.—5.15 P.M., Dr. H. Crichton Miller and Dr. H. C. Cameron: The Nervous Child (Discussion).

UNIVERSITY OF LIVERPOOL POST-GRADUATE LECTURES.

(At 3.30 P.M. each day.)

MONDAY, Nov. 26th.—(At the Children's Hospital.) Dr. Johnson: Paralysis of Spinal Origin.

TUESDAY.—(At the Southern Hospital.) Mr. Nuttall: The Clinical Diagnosis of Peptic Ulcer.

WEDNESDAY.—(At the Northern Hospital.) Dr. M. Bligh: The Diagnosis of Meningitis.

THURSDAY.—(At the Stanley Hospital.) Dr. Gordan Gullan: Nephritis and its Treatment.

FRIDAY.—(At the Royal Infirmary.) Mr. Kelly: Surgical Cases.

UNIVERSITY OF SHEFFIELD POST-GRADUATE LECTURES.

TUESDAY, Nov. 27th.—(At the Jessop Hospital.) 3.30 P.M., Mr. King: Symptoms and Diagnosis of Adenomyoma of the Pelvis.

FRIDAY.—(At the Royal Hospital.) 3.30 P.M., Dr. Percival Hay: Iritis.

MANCHESTER ROYAL INFIRMARY.

TUESDAY, Nov. 27th.—4.15 P.M., Mr. W. R. Douglas: Chronic Mastitis.

FRIDAY.—4.15 P.M., Prof. J. S. B. Stopford: The Sensory Pathway.

SALFORD ROYAL HOSPITAL.

(Special Course on Surgical Tuberculosis.)

THURSDAY, Nov. 29th.—4.30 P.M., Mr. R. Ollerenshaw: Joint Tuberculosis.

Notes, Comments, and Abstracts.

PROGRESS OF MEDICINE AND SURGERY IN IRELAND.*

An Abstract of the Fellowship Address delivered at the Clinical Congress of the American College of Surgeons, Chicago, on Oct. 26th, 1923,

BY SIR W. I. DE C. WHEELER, M.D. DUB.,
F.R.C.S. IREL.,
PRESIDENT, ROYAL COLLEGE OF SURGEONS IN IRELAND.

[AFTER expressing thanks and appreciation concerning his election as an honorary Fellow of the American College of Surgeons and for the high compliment of being asked to deliver the Fellowship Address, the speaker continued:—]

It is natural that we in the surgical profession in Ireland give pride of place to American surgeons deep down in our hearts. Many of the greatest of them bear Irish names; we are kinsmen, blood is thicker than water, and, furthermore, the donors and the recipients in the transfusion of the two races belong to the same group. May the members of the medical profession of the two lands be joined in brotherhood for ever in the service of mankind.

Influence of Travel.

Uppermost in my thoughts at the moment is the influence of travel, of reading, of writing, and even of speech-making, on the progress of surgery; and here I turn to the great Osler, born in Canada, adopted by America, embraced by England, and beloved by all. He refers to students who wish to have the best that the world offers. "Let me suggest," says he, "that the lines of intellectual progress are veering strongly to the West, and I predict that in the twentieth century the young English physicians will find their keenest inspiration in the land of the setting sun." He had, as we have in Ireland, "a love for the land where dreams come true; dreams of more secure reward for honest industry; dreams of freedom from the irksome restraints and conventions which have outlived their day; dreams of equality, not of the cap-in-hand apologetic kind, but frankly avowed and sincerely prized equality which makes the exceptional truckling to rank by the few a subject of hearty laughter." I have quoted the words just now of my father-in-law, who last year returned from America, after a memorable experience as the guest of the American Bar Association.

A close connexion exists between medicine and the law, and each in turn is linked up from times immemorial with literature and the church. What a combination of forces, what an irresistible army, brothers in arms defending the strongholds of science and learning, allies taking the offensive against ignorance and error.

But let us return for a moment to the question of travel, for those of us who live in a small island find it difficult to realise and to attach sufficient importance to such matters. Osler, with a great wide outlook, deplores intellectual infantilism and that disease known as Progeria, in which, as if by the touch of the wand of some malign fairy, the victim skips adolescence, maturity and manhood, and passes to senility, wrinkled and stunted, a little old man amongst his toys.

Have any of you great consultants in a big land seen cases of swelled head and writer's cramp sometimes develop from never using the pen? In small countries such conditions often run hand in hand with the ailments to which Osler refers. "Ten years of successful work in a small place may tend to make a man touchy, dogmatic, intolerant of correction, and abominably self-centred," unless he seeks inspiration and enlightenment from his brothers abroad.

Journal and Monograph versus Text-book.

Travel, reading, and writing are as sign-posts pointing the direction of the straight road which leads to scientific achievement and to legitimate success. By looking and reading we are enabled to avoid the luring and darkened pathways which, no doubt, may end for some in material possession and prosperity, but without real reward. Such pathways are also open to the medical frequenters of race meetings and saloons and to gamblers on the Stock Exchange. Progress along the straight road is not easy.

With regard to writing: I have seen men—some of them colleagues of my own in the surgical profession in Dublin—dictate without note or reference work of first importance in unsurpassed language and with little effort. To others, writing is a grind, a laborious task. Books and the printing press have accomplished wonders in helping forward the surging throng in search of truth. Journal literature and monographs are the literary rocks on which workers in medicine and surgery should be content to stand. Text-books fall by making mountains out of molehills, and persisting in the retention of unwieldy classifications and bewildering names. I have been told of students in their final academic years, who, by misdirected diligence in the lecture theatres and libraries, were left uncertain whether anaphylaxis and prophylaxis were medical terms, or the names of Russian and Grecian generals.

Medicine in Ancient Ireland.

Much of the ancient medical history of Ireland is traditional and legendary, but the people in bygone days were not devoid of literary culture. It is interesting to note that the Royal College of Surgeons in Ireland was the first modern licensing corporation in Great Britain and Ireland to admit women, and to appoint them to the highest offices in its gift. The ancient laws of Ireland, the Brehon laws, codified at the request of St. Patrick, A.D. 438, refer to the remuneration and responsibility of medical men. If one person wounded another, the aggressor not only was obliged to pay a fine to the injured one, but provide him as well with maintenance and skilled medical care. What a pity the Brehon laws are not still in force! The profession of physic passed from father to son, an Irish custom which persisted until comparatively recent times. The ancient Irish doctor was shrewd enough to travel. He found inspiration in the work of his foreign colleagues, and taught posterity an important lesson thereby. Representative Irishmen of all professions remained abroad, and were found occupying distinguished positions in the various schools of Europe.

Ancient manuscripts prove how admirably Irish physicians kept in touch with the advances of learning in continental centres; a thirst for knowledge, augmented by a keen observation of the sick under their care, brought medical and surgical science to a high pitch of perfection in the Ireland of bygone days. Towards the end of the sixteenth century progress came to a standstill. Science and art decayed; Ireland was torn by strife, no shelter for learning remained, and the old worthy position held when Egyptian, Grecian, and Roman thought dominated the world, was lost to Ireland for a time. This relapse was intensified by the failure of the Irish to grasp the revolution in learning brought about by the printing press. The art of printing was neglected until nearly 100 years after its adoption by the progressives of other lands.

This was a distressing period for Irishmen to contemplate, but soon came a reaction, and we turn over the pages of medical history to find, after 100 years, the names of Colles, Graves, Stokes, Corrigan, Butcher, Tufnell, and many others. In recent years Irish surgeons and physicians have been engaged in a heart-breaking struggle in their efforts to advance, and this brings me to the antagonism which exists between the ideals of the medical profession, on the one hand, and the ideals of politicians on the other. The term politicians does not include those great statesmen to whom the very life of liberty now, and in the past, owes its existence, nor does it apply to those unostentatious whole-souled individuals who give their lives to the public service. I use it in the broadest sense to include those whom the world would be better without.

After all, our entire outlook on life, from the time we enter the medical school until we pass on into silence, is entirely different from the view taken by politicians and their cult. Whether we are biologists or craftsmen, we try to keep on a path which takes a direction through accurate observation and logical reasoning to the goal of scientific truth. The road of political life, on the other hand, leads, through a jungle of words and sentences, to ambiguity and nowhere. Modern statecraft, to some extent, is based on the belief that the world can only assimilate small doses of truth at a time, that a big dose is poisonous and liable to kill, and that the public should be cured of their political ills by homœopathic methods. "I always hold," said Mr. Gladstone, "that politicians are the men who, as a rule, are the most difficult to comprehend."

The College of Surgeons in Ireland.

When the College of Surgeons in Ireland was born, in 1783, political upheavals were the order of the day. On recent events I need not touch, beyond this, that we in the College are trained to be optimists, and to assume that, until a patient is dead, our efforts at treatment will be rewarded by success. Our optimism extends to a profound belief in our country, and that the present ship of State will be steered into peaceful and happy channels.

Few institutions in Ireland can claim a record such as ours over 140 years. If anyone should ask me how it is that this College of ours has survived in a robust condition through all the storms and passions of the past and present, I would say because it rested content in strictly attending to its own affairs.

America has taught us the power of self-reliance; we have felt her influence, and have been stimulated by her example. I bring you, then, fraternal greetings on your tenth birthday from the medical profession in Ireland, and the hope that as one decade follows another you may continue to advance and prosper, until finally your great efforts will triumph over the diseases which are decimating mankind, and that you will be crowned by humanity itself with the laurels which belong to victory.

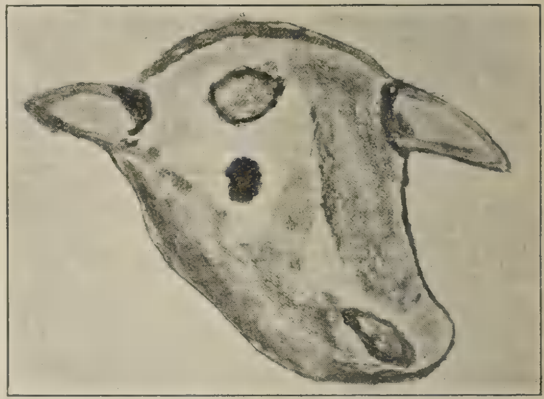
A PREHISTORIC BULL.

To the Editor of The Lancet.

" Non cuivis homini contingit adire Corinthum."

Sir,—A free translation, up-to-date, of the above Horatian verse may perhaps be allowed: "We cannot all hunt for fossils in the Gobi desert." At the same time, by means of a habit of observation useful finds may be made even in the London desert.

For about 18 months I have been watching a strange mark in a York paving-stone on Haverstock-hill, Hampstead. The wear and tear of innumerable feet has brought to light a fine section of a bovine head, showing crest, horns with their cores, one orbit, one nostril, and muzzle. The accompanying illustration is from a reduced drawing. Mr. Winter, the Hampstead Borough Engineer, has kindly had the stone removed for safety to the Town Hall. According to Prof. Geikie's geology York stone is either Permian or Triassic. Possibly human remains may be discovered in a similar deposit. I am, Sir, yours faithfully,



Vere G. Webb, M.R.C.P. Irel.

Haverstock-hill, N.W., Nov. 20th, 1923.

PUBLIC HEALTH IN ST. LUCIA.

The total population on Dec. 31st last was 53,221 (24,399 males and 28,822 females), or 228 to the square mile. The birth-rate in 1922 was 39·0 per 1000 and the death-rate 26·0 per 1000. The principal hospital, the Victoria, is situated within half a mile of Port Castries, and is in charge of a resident surgeon, who has under him a European matron and a full staff of dispensers and nurses. There were 1571 patients admitted during the year, the daily average number under treatment being 76·3. The surgical operations carried out numbered 421. There is a wing attached to the hospital known as the "Baron Ward," in which patients of the wealthier class may receive medical and surgical treatment. Extensive use is made of this ward and during the year the fees received from persons treated therein amounted to £200. Twenty-six patients were admitted to the lunatic asylum at La Toc, the daily average number in confinement being 90·2. One inmate was discharged as cured and ten died. Asylums for paupers and for persons suffering from yaws and leprosy are located in the Soufriere district under the supervision of the medical office of that district and a visiting advisory committee. The daily average number of inmates in the pauper asylum was 93. At the yaws asylum seven patients were admitted and ten discharged. The treatment by kharsivan at the outdoor dispensaries throughout the colony of persons suffering from the disease has proved so successful that it is hoped in the near future to close this hospital entirely. There were 15 patients in the leper asylum at the commencement of the year, and three were admitted; there were three deaths and no discharges. At Dennery, Soufriere, and Vieux Port there are small casualty hospitals for accident and emergency cases; 14 patients were admitted during the year to these institutions.

W. H. C.—Hartmann's pouch is an anatomical structure and is not known to have any pathological significance although it is apt to obtrude on the surgeon who is performing a cholecystectomy.

An Address
ON THE
VIS MEDICATRIX NATURÆ.

Delivered to the Medical Society of Leamington on Oct. 20th, 1923,

BY SIR FREDERICK W. MOTT, K.B.E., F.R.S., M.D., LL.D., F.R.C.P. LOND.

A RECENT visit to Leysin in Switzerland, where I saw how much could be done in the prevention and cure of disease by sunlight, pure dry air and the atmosphere of cure, has led me to select as a subject the vis medicatrix naturæ. I considered this appropriate for an address to medical men practising in a town which has long been famous as a health resort. It was Voltaire who said that doctors pour medicines of which they know little, into bodies of which they know less. Since the days when he lived medical science has made great strides, and doctors now know much more about the physiological action of drugs and of the structure and functions of the human body. Every year brings fresh discoveries of the causes of disease and of the means by which they may be prevented and cured. Medical men might now resent the dictum of Voltaire which I have quoted, but they would recognise the truth of the following principles which he laid down:—

> Régime in diet is better than medicine. Eat moderately what you know by experience you can digest, for only that which you can digest is good for the body. What is the medicine which makes you digest? Exercise. What will repair your energy? Sleep. What will lessen incurable ills? Patience. What can change a bad constitution? Nothing.

This is my text, with the benefits of sunlight and pure air added.

The body is a store of energy which is continually being discharged in the performance of vital functions and renewed during sleep. The maintenance of the balance between storage and discharge of energy under varying environmental conditions largely depends upon the inborn constitution or natural defences of the body against noxious agents from without. This inborn disposition is strengthened by a healthy regular mode of life and freedom from anxiety and worry which, by hindering digestion, assimilation, and nutrition, and by causing sleeplessness, prevents storage and recuperation of energy.

MICROBES AND DISEASE.

The germ-theory of disease initiated by Pasteur laid the foundations of modern medicine and surgery, and I was a student at University College when antiseptic surgery was introduced to London by Lister. At that time a great discussion was taking place between Pasteur and his followers with my teacher the late Dr. Charlton Bastian on spontaneous generation. Dr. Bastian showed that water in which a little hay had been boiled for some time and the flask sealed up generated bacilli, and he argued from this that spontaneous generation of the microbes had occurred. His facts were right, but his inference was wrong, for it was subsequently shown that the desiccated spores of bacilli resist boiling. This was a new fact of great practical importance, especially in regard to such diseases as tetanus and anthrax. Prof. Tyndall took part in the controversy and showed that culture-tubes could be opened in a pure atmosphere, such as at the top of the Bel Alp in Switzerland, without germs generating; because the pure atmosphere on a mountain reveals in a beam of sunlight very few floating particles, and sunlight, as shown by Downs and Blunt as early as 1877, has a powerful bactericidal action. I was much impressed by these experiments of Tyndall, reasoning that inasmuch as particles of coal dust get into the lungs and are deposited there, it was possible that germs of disease might get into the body but be continually destroyed by the natural defences. The skin and mucous surfaces of the respiratory and alimentary canals act as natural barriers against the entry of micro-organisms; still I thought that inasmuch as osteomyelitis, an infective disease, occurs without the mode of entry of the germs being known, it was possible for microbes to pass through the mucous and other barriers and get into the tissues and fluids of the body. To test this question of entry of microbes into the body during life, in conjunction with my fellow-student Victor Horsley, a number of experiments of the following nature were made: Animals were killed and their organs (for example, kidneys and spleen) were taken out under the spray, placed in pots containing boiling paraffin, and these were kept at the body temperature in an incubator. The organs were thereby cooked on the outside, nevertheless the middle parts underwent putrefaction, causing the paraffin to dome up with gases formed by the generation of micro-organisms. It could not be said that these animals were kept under hygienic conditions; and it may be assumed that at the time of their death some organisms or their spores were still in the organs undestroyed, possibly in leucocytes.

These experiments would suggest that in unhygienic environmental conditions the natural defences of the body are engaged in a continuous struggle against numbers of microbes, specific or otherwise. Consequently, if the body is invaded by a specific organism causing at first a local lesion, such as tuberculosis, the natural defences would be less available to combat the disease. For similar reasons impure air and unhygienic conditions favour secondary microbial infection by pyogenic organisms. This is the most frequent cause of fatal results in tuberculosis, influenza, scarlet fever, small-pox, &c. The importance of chronic septic infection by pyorrhœa alveolaris, by decayed teeth and stumps, or by infected tonsils cannot be over-estimated. They are a continuous drain on the natural defences of the body and act as a direct or indirect cause of many diseases.

THE BACTERICIDAL ACTION OF SUNLIGHT.

Robert Koch, in 1890, showed the great sensibility of tubercle bacilli to sunlight, and Strauss proved that two hours' exposure to light was sufficient to sterilise a culture. Sputum containing bacilli spread out on a glass plate are killed in ten minutes by the action of sunlight. The rays which kill are not in the spectrum but are in the ultra-violet rays. The freedom of the air from micro-organisms largely, therefore, depends upon sunshine, and this supports the proverb "Where the sun does not enter the doctor goes." In 1893 Finsen published his first series of experiments upon phototherapy or heliotherapy. This led to a great advance in our knowledge of the properties of light in relation to the treatment of skin diseases. Sunlight for the treatment of wounds was first employed by Bernhard of Samaden in 1902, who, having discovered the absence of putrefaction of meat when exposed to the action of the sun in a high mountain atmosphere, treated a large operation wound by exposure of the affected part to the rays of the sun. The result was so satisfactory that he was led to extend the application of sunlight to tuberculous lesions. The greatest credit is due to Dr. Rollier, who in 1903 opened the first clinic for surgical tuberculosis. Unlike Bernhard, he advocated the general sun-bath as distinct from the local sun-bath. So great was his success that in 1910 he opened his École du Soleil at Cergnat, near Leysin, for the treatment of children predisposed by enlarged glands to tuberculous infection. The principle of heliotherapy introduced by Dr. Rollier has been adopted with great success by Sir Henry Gauvain at Alton and Hayling Island, and recently in other places. Sir Henry Gauvain in a foreword to the translation of Dr. Rollier's work "Heliotherapy"[1] points out that—

> The sun's rays are the source of all vital energy, they are the great vital tonic..... Dr. Rollier, he remarks, is the high priest of the modern sun-worshipper. His work is not only a revelation, but an inspiration. His methods of treatment

stimulate rather than supplant the efforts of Nature to defend the body against disease. Its value in preventive medicine will be increasingly appreciated after experience in its employment has been acquired. He advocates schools in the sun, insolation in the isolation hospitals, and transference of hospitals for chronic disease to sunny localities. Wherever the sun shines and the requisite skill exists for its utilisation, there insolation may be usefully employed.

From my own knowledge gained at Leysin, I can endorse all that Sir Henry Gauvain says.

Sunlight and Rickets.—Now there is a disease which is known abroad as the Englische Krankheit because of its prevalence in this country. It is rickets. We have rightly regarded improper feeding of infants as the cause of this disease (a food-deficiency disease)—lack of fat-soluble vitamins; but this is not the only cause; overcrowded dwellings where the sunlight hardly ever enters, such as are found to be the habitations of millions of our poor population dwelling in towns and cities, are as much responsible for this English disease as food deficiency. That this is so is shown by what happened to the children of Germany who suffered with rickets on account of a deficiency of animal fat, for it was found at Frankfort that a daily sun-bath (in spite of the continuance of the food deficiency) prevented the occurrence of rickets. Dr. Alfred Hess, of Columbia University, at the Home for Hebrew Infants, New York, found that the amount of phosphorus in the blood of babies rises from spring to autumn and falls from autumn to spring, whilst the incidence of rickets consentaneously falls and rises.

SUN CURE OF SURGICAL TUBERCULOSIS AT LEYSIN.

Impressed by the reported great success of the sun cure I recently took the opportunity offered to English medical men of visiting Leysin, and I attended a short course of lectures and demonstrations given by Dr. Rollier and his staff of assistants and experts. Dr. Rollier, with whom I had several conversations, told me that he was formerly an assistant of the great Swiss surgeon, Prof. Kocher of Berne, but he was obliged to leave Berne on account of his wife's health, and he had to seek a place where there was no practising doctor, but where there was plenty of sunshine and pure air. His wife made a perfect recovery and has assisted him in his great pioneer work, which he has the satisfaction of seeing rapidly spreading to all civilised countries. He told me that he had seen the failure of surgical intervention in tuberculosis of the bones, the spine, and joints, and that this had led him to try heliotherapy. He took us to the châlet where he commenced the sun treatment. This small clinic contains about 30 of the poorer class of patient, but there are now a great many clinics for all classes of patients who come from all parts of the world. The one I stayed in, "Miremont," was like a very first-rate hotel, with large sunny rooms, each with a verandah on to which the bed could be wheeled, well-furnished and appointed, and the meals, although simple, were wholesome and appetising. On the top of the building was the solarium and the patients were taken up in their beds in a lift. Concerts and broadcasting from Paris, kinematograph, and performances by the staff and some of the convalescent patients were given several nights while I was there.

Lectures and Demonstrations.—The lectures and clinical demonstrations were given by Dr. Rollier and his assistants. The expert radiologist, Dr. H. J. Schmid, showed a series of skiagrams of normal conditions of the spine, the pelvis, and bones of the limbs, followed by demonstrations of excellent skiagrams and various pathological lesions of these structures, especially of those due to tuberculosis and osteomyelitis. In the course of these demonstrations a number of skiagrams of lesions of these structures before and after treatment were exhibited.

Dr. Rollier pointed out that the whole principle of the treatment of tuberculous disease of bones and joints was to obtain a spontaneous cure. The only surgery performed was the aspiration of pus by puncture with a trocar when an abscess had formed, and this was rarely necessary. He said it was the secondary infections that did the mischief and were so difficult to combat successfully, because the suppuration, if prolonged, caused amyloid disease. In his clinical lectures he showed the mode of treatment and the results obtained both by photographs before treatment, and skiagrams taken at intervals during treatment. The patients were brought into the lecture room on movable beds. He explained and demonstrated the various devices he adopted for the extension of hip, knee, and ankle to prevent deformity while undergoing the sun cure. It was remarkable how well developed the muscles of these patients were, in spite of prolonged immobility, and he attributed this to the action of the sun's rays producing an increased flow of blood to the parts exposed. It is possible, as will be pointed out later, that energy may be absorbed by the blood and distributed over the whole body, and it is not improbable that by the stimulating action of the light the reflex tonic contraction of the muscles and their nutrition are increased.

At the clinics which I visited I saw cases of Pott's disease kept lying on their faces, and by means of supporting bags, filled first with millet seed and later with sand, spinal curvature was gradually reduced during exposure to the sun's rays. The products of inflammation are thereby absorbed, granulation tissue is formed, and calcification with fixation takes place. Many cases were shown, and X ray pictures before and after treatment exhibited. Two young girls with hip disease who had recovered, with admirable movement and able to bend hip and knee and ankle, were shown to us, and it would have been difficult from their walk to know that there had been grave disease. Dr. Rollier said he had never had a case of tuberculous ankle or wrist in which free movement had not followed treatment. Particularly interesting were some skiagrams of a case of tuberculous knee-joint before and after treatment. These skiagrams clearly demonstrated that not only were all the inflammatory products absorbed, but that new cartilages had been formed having a normal appearance. This seemed difficult to explain, and I would suggest that just as in regeneration of a nerve after section the new outgrowing fibres from the central end find their proper termination in the skin and muscle as if by an innate association cell-memory, so the undestroyed cartilage cells proliferate, and by an innate memory so dispose themselves under the stimulation of the dynamic forces of pressure, exercised in gait and station as to take on their original functions in the joint. Every stage of spondylitis and arthritis was shown in young and old and all were doing well and making for recovery. At the châlet, where Dr. Rollier first commenced the sun cure treatment, I saw an Englishwoman with tuberculous arthritis of the right shoulder with secondary microbial infection and suppuration. There were two fistulæ, besides which there was tuberculosis of both apices of the lungs. When she came to Leysin she had a swinging pyrexia and her photographs denoted misery and cachexia. Three months had elapsed, the temperature was normal, she looked, felt, and spoke as if she were a happy woman and hopeful of recovery. She had put on 9 kg. in weight, and under the healing and bactericidal influences of the sun and general improvement in health the fistulæ had healed up. Another remarkable case was one of Pott's disease in a child who came with abscess formation, prolonged suppuration, and albuminoid disease of liver and kidneys; this was treated in the usual way, but milk was the only nourishment for one year. The urine no longer contained albumin and the liver was no longer enlarged.

I saw a child that was freckled in the face and Dr. Rollier remarked that this patient would require very careful handling, as people with freckles did not pigment readily; likewise, the great difference between the skins of dark and blonde subjects must be borne in mind, as the latter are much more sensitive to sunlight and require extremely careful treatment if over-exposure is to be avoided. The experimental researches of Dr. P. Bloch point strongly to the fact that the formation of pigment must be sought in an enzyme which he shows exists in the basal cells of the epidermis. It cannot be demonstrated experimentally in the skin of an albino animal. This ferment is activated by all agents which normally produce pigmentation, the action of light being particularly striking. It is called dopa-oxydase. It may be inferred that the Mediterranean type of human beings would have relatively much more of this ferment in the cells of the rete Malpighii (where pigment is normally deposited) than the Nordic type. It is not inconceivable that the freckling of the skin may point to an admixture of unblended Mediterranean and Nordic types of skin in which the latter is, for the most part of the body surface, dominant. The vulnerable parts of the skin to the invasion of micro-organisms are the sebaceous glands and hair follicles. Acne, boils, and carbuncles are caused by infections of these structures. Sun treatment by its bactericidal action prevents the occurrence of these affections. I did not see acne in any of the patients, nor did I see it in any of the boys and girls at the École du Soleil.

I will now briefly allude to some of the general principles of technique which I saw. The method consists in beginning always with the feet and insolating both legs and arms before exposing the abdomen and thorax. By this means a general idea of the tolerance of the patient to sunlight is attained before the more vulnerable parts of the body are exposed. Short periods of exposure alternating with periods of rest—e.g., 10 to 15 minutes—make the body tolerate a much greater total amount of sunlight than would be possible with one long sun-bath, which is more fatiguing to the patient and more irritating to the skin. A series of moderate reactions three or four times a day for 15 minutes causes more rapid acclimatisation than is the case with a single bath of 30 minutes. When once, by this graduated system of exposure, the patient is pigmented all over there is no longer any danger and the patient may then have several hours of sun-bath every day.

LOCAL REACTIONS.

One effect of the sun-bath is analgesia and this is most marked in lesions of the joints and abdominal cavity. Another phenomenon of local reaction, if the lesions be at all active, is that the affected part becomes tense and uncomfortable; the treatment should then be discontinued or an acutely painful reaction will occur. When a tuberculous joint or glands are exposed there is a swelling of the part affected and a similar phenomenon, though less easily demonstrable, occurs in the region of a deep-seated abscess. In the region of the lesion sensible perspiration occurs, while the parts around remain dry. A rise of temperature in the neighbourhood of the lesion is a constant occurrence. In a patient who is already pigmented there is a difference of colour in the neighbourhood of the lesion unless there is a sinus or operation wound, then a much darker pigmentation appears in the affected region. Dr. Rollier laid great stress on free drainage. Where there is suppuration gauze was used as a dressing. Sinuses heal up and bone sequestra come away under the influence of the sun treatment.

Those who are interested in the theory and practice of this important development of the vis medicatrix naturæ should study "Heliotherapy."[1] Dr. A. Rosselet, who contributes a valuable chapter on the scientific basis of heliotherapy, comes to the following conclusion:—

> "In heliotherapy, success must not be attributed solely to the action of light, as the quality of the air breathed, and of the nutrition absorbed, with rest, are also factors of great importance. On the other hand, it would be a mistake to look upon light as merely an adjunct to those other factors determining cure." Dr. Rosselet suggests that light may be absorbed by the blood, and "the energy given out by the radiations is stored and carried in the blood-stream to every part of the body; when liberated it stimulates the intracellular processes of oxidation and reduction."

Sir William Bayliss does not apparently accept this as a proven theory. No doubt there is an unusual metabolism of the body which fully accounts for the well-developed musculature in spite of the immobility, but the stimulus of sunlight on the sensory nerve-endings in the skin would tend to induce a uniform continuous reflex tonus in the muscle.

ATMOSPHERE OF CURE.

The general sense of well-being noticed in the patients may also be due to the "atmosphere of cure" inducing faith, hope, and patience to bear their lot. The bien-être thus induced plays a very important part in the recovery by promoting digestion, assimilation, and nutrition, also natural sleep. These necessary conditions for the storage of mental and bodily energy and for improving the natural defences of the body may be seriously interfered with by impatience, discontent, and anxiety which, by staying the flow of the appetite juices, interfere with digestion, assimilation, and nutrition. Again, insomnia and unrefreshing sleep—disturbed by dreams—occur where faith and hope are absent. Depressing drugs have to be administered to produce sleep and rest, and as a consequence there is a lowering of the store of vital energy. If the sun treatment is so successful in the cure of tuberculosis why, it may be asked, should it not be adopted for the prevention? Why not treat sick patients on open verandahs in the country where pure air and sunlight can be found? Why should chronic cases be kept in large expensively constructed buildings in our large towns and cities, when they can be so easily and comfortably transported to salubrious spots in the country? These are questions to which the Ministry of Health might well give attention. Before the war I visited some of the schools in Birmingham with Mrs. Pinsent and saw an open-air school for tuberculous children; I remarked then that the children looked healthier than the children in the normal schools. Would it not be better to have all schools so constructed as to obtain the greatest amount of sunshine and fresh air? Not until we can rid get of slums and back-to-back houses in our towns and cities, where the sunlight cannot enter, and house our poor people in proper dwellings will the reproach of rickets as an English disease be undeserved.

The establishment of an "atmosphere of cure" in sanatoriums largely depends upon the brain directing and presiding over the organisation and administration. Sense of discipline, morale, and self-respect form essentials for success. The value of occupation and amusement in establishing a sense of bien-être during convalescence cannot be over-estimated as a means of strenghtening the natural defences. My experience during the war showed me how important it was to get the neurasthenic or hysteric soldier to take up some outdoor occupation in which he had an interest. This one could do by not following the usual stereotyped army methods, but by telling the soldier whatever he grew in the garden he could have, or whatever he made in the workshop would be his own property to do what he liked with. The men asked to come and do work, and were not told to come. Again, I am a great believer in the value of music, especially choral singing, as a means of producing a *joie de vivre*.

APPETISING FOOD.

Another matter of importance in establishing contentment is enjoyment of food. Of course, the old adage "hunger is the best sauce" is true, but it is customary among nearly all civilised people to take three meals a day and the pangs of hunger are therefore seldom felt in hospitals, sanatoriums, or institutions for the treatment of the mental or bodily affected, yet how little attention is given by doctors, matrons, or others in authority to find out whether the patients and nurses have *appetising* food. Wholesome food can be made appetising without an increase of cost or labour, and physiological science and clinical observations have taught us that food made appetising by its savour and flavour has a psychic effect, starting a flow of the digestive juices before the food enters the mouth. This anticipatory psychic effect is essential for the enjoyment of food, and it is not sufficiently realised what an important part the enjoyment of food plays in the production of a contented mind. Again, nothing is more conducive to discontent than when unappetising food is made more unappetising by monotony, and when the daily unappetising diet becomes a subject of contemplation. It is not only the morale and spirits of patients which suffer, but the nurses may be found affected upon particular days by contemplation of an especially unappetising meal. Again, I think that doctors and nurses should know how wholesome invalid diets are to be prepared, and how they can be made appetising without being in the least degree made unwholesome. The palate (if it is not vitiated) is a very good guide, and Voltaire was keen enough to appreciate the fact that experience tells one what is good for us and what we can digest. Now, an important matter in the establishment of an "atmosphere of cure" is the well-being, mental and physical, of the nurses. Too often they are overworked, badly paid, and indifferently fed and housed. Nothing but love for their work and hope for better things can then maintain morale, discipline, and that sympathy so essential for the well-being of the patients under their care.

SLEEP.

Sleep is a normal condition of the body occurring periodically in which there is a lessening of vital activity of all the organs of the body. But inasmuch as all vital active processes in the human body are dependent upon oxidation processes, it must be inferred that during sleep there is a diminution of processes of oxidation, as a result of which the body lies quiet with the muscles relaxed, the pulse-rate diminished, the respirations less frequent, and the person does not react to slight sensory stimuli. Secretions are less actively carried on, intestinal peristalsis is diminished, and the pupils are contracted. But the greatest effect is upon the highest level of the nervous system leading to a greater or less degree of unconsciousness. The lower subconscious and the bulbo-spinal autonomic levels are also affected but to a much less degree. It is probable that the whole of the bodily phenomena of sleep are due to a lessening of the oxidation processes at the neuronic synaptic junctions in the central nervous system, so that in deep sleep only strong stimuli or summation of stimuli can pass the synapse and result in a reaction. The waking state is associated with an awareness of alterations of the feeling continuum which is streaming in by all the sensory avenues, and this exæsthesia is integrated with the cœnæsthesia of states of feeling arising from the bones, joints, tendons, muscles, and labyrinth, the glands, and viscera.

The physiological explanation of sleep has never been satisfactory, and there is much to be said in favour of a biological explanation. Throughout organic nature there has been an association between functional activity and sunlight. Throughout the animal kingdom oxidation processes are fundamental to tissue-activity and discharge of energy under the influence of stimuli from the external world resulting in the production of fatigue products and a degree of exhaustion of potential energy which is capable of recuperation by rest. The normal conditions of sunlight and oxidation processes have been habitually juxtaposed in the evolution of the animal kingdom. While at the end of the day till dawn there is a lowering of oxidation processes in response to absence of environmental stimuli, there is a storage of potential energy. The fall in potential energy at the end of the day has in the long procession of ages been associated with a desire for sleep. This manifests itself especially by an inability to keep the eyes open and there is a feeling of fatigue in the elevators of the eyelids which tend continually to droop and shut out the light. R. Semon has shown that habit and memory are based upon the same fundamental principles. When two conditions are juxtaposed in time and place either one will revive the other. Thus if we represent C as sleep, A as night, B as a fall of potential energy and fatigue, sleep is induced habitually by either A or B. Probably B is the more important factor in determining the desire for sleep. Consequently when persons have to work by night and sleep in the daytime, they experience a fall of potential energy at the dawn and a desire for sleep in the day. We must look upon sleepiness occurring not because there is an actual exhaustion of the brain, but in order that it may not be reduced to that extremity. Every normal child, like the adult but in a less degree, possesses a store of nervous and muscular energy over and above that which it requires in ordinary conditions of life; and this statement is borne out by all the known facts, experimental and otherwise, concerning mental and bodily fatigue. The reserve energy certainly varies in amount in different individuals; it is intended only for emergencies and should not be habitually drawn upon. The sense of fatigue and the desire for sleep may be regarded as the protective and the instinctive guardians of this reserve of nervous energy. Both give warning that the reserve is about to be drawn upon, and if the warning is continually allowed to pass unheeded, exhaustion of the highest inhibitory function of the brain cortex ensues, and associative memory thus left unchecked, permits a continuous flow of ideas, resulting in mental excitement and sleeplessness. A vicious circle tends thus to become installed which, if not broken, leads to bankruptcy of nervous potential, with permanent mental irritability and lack of mental energy. A neurasthenic condition, with insomnia, is very prevalent now in highly civilised communities among young adults owing to over-pressure at school and college in competitive examinations; and quite young children of a nervous temperament, owing to parental indiscretion in their upbringing, may suffer from it. Sleeplessness of the child is a sign of nervous irritability and exhaustion, and requires careful attention lest worse evils follow. Darkness, stillness of the body, and silence favour sleep by removing the principal cause of wakefulness and activity of the mind. Habit fortunately permits sleep under the most unfavourable conditions; still, the sleep of young children must necessarily be a broken one in the single-room tenement dwellings of the poor of our large cities. This is an important unhygienic condition relating to mental development; for insufficiency of rest to the brain tends to failure of mental energy. The growing infant requires plenty of sleep; so does the growing child, and especially so when the child is suffering from bodily ill-health or nervous irritability.

I observed that neurasthenic officers and soldiers at the Maudsley Neurological Clearing Hospital during the war suffered with terrifying dreams, and all the while they lasted sleep was unrefreshing. Many neurasthenics could not recollect their dreams, but the fact that they awoke feeling less refreshed than when they went to bed indicated that they had not recuperated their nervous energy. Indeed, most neurasthenics will tell you that as the day goes on they feel better. During the battles of the Somme a considerable percentage of neurasthenic cases were sent back to England soon after they had left the battlefield. Many of them showed the aspect of fear with exophthalmia, von Graefe sign, fine tremors, and high blood pressure. These signs and symptoms persisted all the while the terrifying dreams persisted. It was probable there was an increased functional activity of the adrenal and thyroid glands in response to the emotion of fear.

I will now pass on to a brief reference to the constitution in relation to the reproductive and endocrine systems.

CONSTITUTION IN RELATION TO THE REPRODUCTIVE AND ENDOCRINE SYSTEMS.

What can change the constitution? Nothing, said Voltaire. The natural defences of the body against injury and disease are intimately bound up with and dependent upon the biochemical conditions of the blood, and the interrelation and harmonious interaction of functions of all the organs of the body by chemical messengers, especially those products of secretion of ductless glands. The fathers of medicine were accustomed to speak of the brain, the heart, and the lungs as the tripod of life. We now know that certain ductless glands—e.g., the parathyroid, adrenal, and pituitary glands—are also essential for life. The *élan vital, joie de vivre* of youth is connected with the maturation of the sex organs and the passage into the blood of a hormone which determines the secondary sexual characters and produces a complete mental revolution in youth and maid. A new instinct, the love instinct, with its sentiments and passions is aroused which energises all the organs of the body. In pregnancy there are observable structural and functional changes in the thyroid, the adrenal, and the pituitary glands. Preservation of the species under natural conditions by reproduction denotes a sufficient vital energy for self-preservation with a balance still in hand for propagation. A good animality under proper control generally indicates a good constitution and powers of vital resistance against injury and disease.

For many years past I have been studying the reproductive and endocrine glands in over 100 patients dying in hospitals and asylums, and I have come to the conclusion that certain forms of insanity are associated with a tendency to an inborn deficiency of the reproductive and endocrine systems of glands, and that some of the symptoms can be correlated with a primary regressive atrophy of these organs. There is a progressive atrophy of both the spermatogenic cells and the cells of the interstitial gland of the testis. In a considerable proportion of these cases of insanity atrophic changes of variable degree occur in the thyroid, pituitary, and adrenal glands, and it is probable that other organs such as the liver and the cells of Langerhans of the pancreas and the parathyroids would show histological changes, but I have not yet examined these organs. However, a comparative examination of the reproductive organs and the thyroid, adrenal, and pituitary glands of the cases of primary dementia whether commencing in pre-adolescence, at adolescence, or post-adolescence, compared with the same organs of an acquired mental disease, general paralysis due either to congenital or acquired syphilis, has shown that the former are inborn. For whereas pronounced histological changes from the normal were usually found in the glands of the former, as a general rule, the glands of the general paralytic showed but little departure from the normal, indeed, less than in cases dying of tuberculosis in consumption hospitals. The symptoms of the primary dementia are probably associated with and dependent upon two causes: (1) The failure of oxidative processes in the whole body due to lack of the energising influence of the ductless glands causing suppression of functions and varying states of disintegration of the psychic unity with emotional indifference. (2) Progressive pathological changes in the nucleus of the cortical cells and increase of neuroglia cells proportional to the degree of dementia. This would lead to suppression of function; whereas symptoms due to the first-named causes are capable of improvement and even disappearance with restoration of functions, the latter are irremediable.

It is legitimate to associate the low blood pressure, acrocyanosis, and katatonic stupor with a deficiency of adrenalin and failure of function of the adrenal medulla. Then a return of function of this gland might result and account for the fact that katatonic stupor may pass off and a sudden impulsive behaviour arise, or a return to a fairly normal state may in some cases happen. In the study of sections of the adrenal gland I have been particularly struck with the good development of both cortex and medulla in general paralysis as compared with the primary dementia cases. Again, I have noticed that in all cases that died of septic poisoning, and in some few cases of tuberculosis with secondary pyogenic microbial infection, the whole or nearly the whole of the lipoid content contained in the cells of the cortex has disappeared. There is reason to believe that this substance is a source of the antitoxins; some authorities, indeed, speak of this portion of the gland as antitoxic and the medulla as angiotonic. The cortex, however, has many other important vital functions especially in connexion with reproduction; not only is it of vital necessity therefore for the preservation of the species but by the production of antitoxins it is essential for the preservation of the individual against microbial poisons.

OPOTHERAPY.

I have not time to develop the subject further than to say that there is reason to believe that the vis medicatrix naturæ largely depends upon a good constitution and that a good constitution implies a proper development of the reproductive organs and the ductless glands and their harmonious interrelation. Rudyard Kipling, in a very interesting speech at the Hunterian dinner, said that the God Brahm had hidden the mystery of the man in his own body. Astrologers, alchemists, and philosophers have sought for it outside the body, and until recently psychologists had sought for it only in man's organ of intellect and reason. We are coming more and more to realise that feeling depends for its vital urge, *libido*, or *élan vital*, upon the endocrine and reproductive systems which minister to the primal instincts of self-preservation and propagation through the old involuntary nervous system. Although long hidden and overlaid by the voluntary system, its fundamental importance in relation to human character and behaviour is beginning to be recognised. Only a corner of the veil that hides the mystery of life has been raised. I cannot do better than to quote the opinion of Cannon who has done so much to advance our knowledge:—

> The known influences of these glands are so striking and so important for the welfare of the individual and the race that most naturally hope has been stirred and imagination excited to a remarkable degree. Prophets have arisen who are proclaiming a new gospel. A flare of extravagant fancy is now blazing; all the mysteries of medicine are now to be accounted for in terms of disturbed internal secretion.

When we take a careful account of our present actual knowledge we find large gaps in it; though we talk glibly of the products of these organs, only two effective substances have been isolated and analysed chemically, adrenin and thyroxin. The claims of opotherapy have been largely based upon the undoubted remarkable effects of thyroid gland obtained in myxœdema and cretinism, and recently of insulin in diabetes. Further, despite the assurance of enthusiasts we are lacking really reliable tests for disturbances in many of the endocrine glands.

Medical science is becoming more and more dependent upon natural science in its widest sense. The knowledge that an essential element of thyroxin is iodine led to the discovery that districts in Switzerland and America where goitre was prevalent was due to the insufficiency of iodine in the food and water. For it was found that the administration of small quantities of iodine or a salt of iodine led to the disappearance of this disease of the thyroid gland in the district.

I have only lightly touched upon this subject of constitution in relation to endocrine glands and the *vis medicatrix naturæ*, but I should here remark that Dr. Rollier told me that where he could feel a good thyroid development he gave a good prognosis. I would also call attention to the fact that the majority of cases of primary dementia (dementia præcox) showing regressive atrophy of the reproductive and endocrine glands die of pulmonary tuberculosis with usually secondary microbial infection. This is an indication of a low vital resistance. Cases dying in consumptive hospitals do not show such pronounced changes in the reproductive and endocrine glands as cases of dementia præcox that die from sudden death or acute disease; so that although an exhausting disease such as tuberculosis—especially where there is secondary microbial infection—is a drain on these natural defences, it does not cause the same amount of exhaustion of internal secretions as this primary genetic deficiency (dementia præcox).

Our aim as doctors should be to assist Nature's defences as far as possible, to study the advances in the knowledge of the physiological action of drugs, and the physiology of the human body.

A Post-Graduate Lecture
ON
INTRACRANIAL TUMOURS.

Recently delivered for the Fellowship of Medicine at the Royal Society of Medicine

By H. S. SOUTTAR, M.Ch. Oxf., F.R.C.S. Eng.,
SURGEON AND DIRECTOR, SURGICAL UNIT, LONDON HOSPITAL.

It is customary to include under the term "intracranial tumours" a large number of conditions which have little in common besides the slow and localised character of their development. Cysts, granulomata, chronic abscesses, and true neoplasms have all to be considered, and their inclusion is natural, since the symptoms to which they give rise are almost entirely the effect of their position and their bulk, and only by indirect inference can we conjecture their character. I propose first to touch very briefly on the tumours themselves and the conditions under which they occur, next to discuss the general symptoms to which they give rise, and then to pass on to a more detailed discussion of tumours in sites accessible to surgery.

Varieties of Tumour.

From the standpoint of the surgeon the simplest tumours are the cysts, for mere removal of the fluid will at least relieve the symptoms and may result in a permanent cure. The most important practically are those due to trauma, and those resulting from the degeneration of a glioma. Traumatic cysts arise as the result of subdural or intracerebral hæmorrhage. Their origin may date to a severe moulding of the head during labour, with a probable laceration of the dural septa, but they are a not uncommon result of accidents, sometimes of quite a trivial nature. In both cases they may remain latent for years and may then without any apparent reason commence to enlarge, producing all the symptoms of a tumour.

In a gliomatous cyst the tumour tissue may almost entirely disappear, and may even on microscopic examination be very difficult to discover. But such cysts have a strong tendency to recur, although evacuation of the cyst and the treatment of its wall by fixing reagents has in some cases resulted in long periods of relief.

Of the granulomata, those due to tubercle are the commonest intracranial tumours of childhood, whilst after 20 they are rare. They usually occur in the cerebellum and may waken to activity after a long period of latency. After a period of activity they may again recede, sometimes, unfortunately, after sight has been destroyed by the pressure they have induced. They are often associated with some degree of meningitis, and the production of a diffuse infection is one of the grave risks of their removal, unless indeed they are so substantially encapsuled as to allow of total enucleation.

Intracranial syphilis, on the other hand, is a disease of adult life. It primarily affects the meninges, especially at the base, but it may result in the production of localised tumours, the frequency of which has, however, been somewhat exaggerated by the optimism of physicians. Unless the case is quite definitely one of cerebral syphilis, a positive Wassermann reaction is no excuse for delay in exploration, when the symptoms suggest the presence of a tumour.

Around a chronic abscess there may be formed a wall so dense that even on exploration an actual tumour may be diagnosed. Such abscesses may result from tubercle, or from pyogenic organisms which have reached the brain from local bone infections, especially of the ear, or from such septic conditions of the lungs as bronchiectasis and pulmonary abscess. Every endeavour must be made to remove such an abscess en masse, for opening the abscess, even if followed by drainage, will almost invariably result in a diffuse and fatal infection.

Of true neoplasms we have four groups to consider. From the auditory nerve arise the fibromata which form the characteristic tumours of the cerebellopontine angle, as fascinating in diagnosis as they are baffling in removal. Rarely exceeding a hazel nut in size, they produce symptoms out of all proportion to their size, whilst nothing could be easier than their total removal were it not that it almost invariably costs the life of the patient. Only in tiny fragments and by slow degrees can they be successfully extirpated.

From the meninges arise the endotheliomata, the one great hope of the cerebral surgeon. They usually arise from the dura of the anterior vault, probably from the lacunæ of the superior longitudinal sinus. They may grow to a considerable size, and though they compress it they never invade the brain. On the other hand, they may invade the skull in a remarkable manner, stimulating bony growth and leading to the formation of external bony tumours. They are easily removed, they do not tend to recur, and after their removal the compressed brain may in many cases regain completely its lost function.

From the brain itself only the gliomata are known certainly to arise. They may be diffuse and infiltrate the brain till all demarcation is lost, or they may be so far encapsuled as to resemble endotheliomata, or, as already stated, they may form degeneration cysts. They never invade non-neural tissues, but from the brain itself they can never be extirpated, and they always tend to recur. They are the true malignant tumours of the brain, though only to the brain itself are they malignant.

Finally, within the cranial cavity we may find secondary tumours arising from carcinoma, melanotic sarcoma, and other growths in other regions of the body. They are only to be diagnosed in order to be avoided.

General Symptoms.

As I have already said, these tumours have little in common besides the slowness of their growth, the localised character of their development, and the similarity of the symptoms which they produce. These symptoms may be conveniently considered under three groups: General symptoms, due to interference with the brain as a whole; regional, due to interference with some special region of the brain; and local, due to interference with local nerves.

These symptoms are not directly dependent on the position of the tumour, and are essentially due to the increase in intracranial pressure which it produces. Indirectly, however, the position of the tumour is of vital importance in their production. To mere bulk the brain shows great powers of accommodation, and nothing is more astonishing than the gigantic size to which a tumour may grow unnoticed, on one condition only, that it does not interfere with the flow of cerebrospinal fluid. Continuously secreted by the choroid plexuses in the lateral ventricles, this fluid flows through the foramina of Monro to the third ventricle, whence it is conveyed by the aqueduct of Sylvius to the fourth ventricle, escaping by the foramina of Luschka and Magendie into the subarachnoid space, to be finally discharged by the Pacchionian bodies into the superior longitudinal sinus. A tumour involving the cerebral hemispheres may grow to a huge size without affecting this vital circulation. On the other hand, in the interpeduncular space, in the corpora quadrigemina, or at any point below the tentorium, even a small tumour may obstruct the flow, and, by producing a secondary hydrocephalus, may cause a sharp rise in the intracranial pressure, and with it general symptoms of the greatest severity. The contrast between supra- and infra-tentorial tumours is very largely due to this consideration alone. Above the tentorium the general symptoms are mild and surgery is comparatively easy; below the conditions are always critical, and surgical interference will only too often be fatal. By the secondary hydrocephalus the cerebellum is forced down through the foramen magnum till it forms a cone which may reach as low as the third cervical lamina, crushing beneath it the medulla and the vital centres which it contains.

These general symptoms include the classical symptoms of intracranial pressure, headache, vomiting, and papillœdema. I would insist, however, that only in a secondary sense are these the symptoms of an intracranial *tumour*, and that every effort should be made to effect a diagnosis before they arise. To wait for them is as unreasonable as to wait for acute intestinal obstruction before diagnosing a stricture of the colon. When, however, these classical symptoms occur they are of great importance and present very definite characters. The headache is constant, but with severe exacerbations. It is often severe on waking, and it is increased by anything which raises the intracranial pressure, such as exertion, excitement, or even stooping. Vomiting is also most marked on rising in the morning; it is independent of food, unaccompanied by abdominal pain, unpreceded by nausea, and therefore occurs as a sudden projectile act without warning. Papillœdema may be present in a severe degree before it becomes subjectively obvious to the patient in blurring of vision, but, as a rule, when it is at all marked, a careful examination of the visual fields will show some degree of contraction for colour and for small white objects. Transient attacks of blindness may occur, but persistent diminution of vision means that atrophy has commenced, and complete recovery of visual power is then impossible. The swelling of the disc may be accompanied by retinal hæmorrhages and is generally, though not always, most marked on the side of the lesion.

It should be noted that almost identical symptoms occur in renal disease, severe anæmia, and lead poisoning, when they are the result of cerebral œdema, which again produces an increase in the intracranial pressure. The exclusion of these conditions is, however, a simple matter. Among other general symptoms we should mention a progressive mental dullness, sometimes bordering on drowsiness, attacks of giddiness, not, however, of such sudden onset as those which occur in Ménière's disease and transient diplopia. The last may only occur once or twice and in the earliest stages, long before the onset of the classical triad of symptoms; it is very transient and may seem to the patient too trivial to mention. If, however, it really occurred it should be regarded as a symptom of the very first importance in the diagnosis of an intracranial tumour.

From this brief review of the general symptoms of intracranial tumours we must now pass on to a consideration of their regional effects. But before taking up in detail the effects of tumours in different regions let us first consider for a moment how these effects are produced. The mere pressure of a tumour on the actual cells of the brain would probably be entirely without result, were it not for the interference with the cerebral circulation by which this pressure must in practice be accompanied. It is a clearly established law of cerebral pathology, beautifully elaborated by Trotter, that congestion means irritation, and anæmia paralysis. Now the first effect of the pressure of a tumour must be interference with the venous return and congestion of the region of the brain concerned. If this happens to be the motor cortex the irritation may show itself in the production of Jacksonian fits, starting in that region of the body which the particular portion of the motor cortex supplies. As the tumour grows and the pressure increases the capillaries will be compressed, anæmia will be produced, and paralysis will replace the irritation. But as the tumour grows, in addition to an increase in the actual pressure at any one point, we have an extension of the area involved, so that in fact we shall have a spreading area of paralysis surrounded by a zone of irritation. And the whole effect is enhanced by the fact that every now and then an acute œdema may arise around the advancing tumour, increasing the general pressure and producing a dangerous exacerbation of the symptoms, sometimes the abrupt prelude of a fatal termination.

Tumours of the Rolandic Area.

The most important portion of the cerebral cortex from the point of view of intracranial tumours is undoubtedly that which lies in front of the fissure of Rolando, the precentral or ascending convolution. It differs histologically from any other portion of the cortex, since here alone are found the clusters of giant pyramidal cells of Betz, from which arise the great pyramidal tracts. It is essentially the final area through which the volitional control of the brain is conveyed to the muscles. It originates nothing, but it transmits movement formulæ for the execution of various skilled acts, the formulæ themselves being prepared by the synthetic action of other centres—visual, auditory, sensory, or psychic. It has, in addition, the important function of inhibiting muscular tone, the muscles being thus held ready for instant response to the transmitted formulæ. Its destruction, therefore, leads to a loss of volitional control and to an increase in muscular tone which hampers useful action.

In this area the different portions of the body are represented by centres arranged in a very precise manner. At the extreme upper end commence the centres for the leg, the toes and ankle being represented actually on the mesial surface of the hemisphere. Passing downwards, the knee and hip are followed by the trunk, which lies just opposite the superior genu of the fissure. Below this come in order the shoulder, elbow, wrist, fingers, and thumb. Opposite the inferior genu is the neck, and immediately below this the face, the centre for the eyelids lying close to the centre for the thumb. The tongue and larynx follow. Just in front of the hand area is a special area for the control of the conjugate movements of the eyes and rotation of the head to the opposite side.

When a tumour affects this region it gives rise to symptoms, as I have already explained, by the interference with the circulation which it produces. When the pressure is slight and only congestion results, irritation is produced; when it is more severe we have anæmia and paralysis. And inasmuch as the tumour is steadily advancing, there will usually be a zone of paralysis surrounded by a zone of irritation. The phenomena of irritation in this region have a very characteristic form, first described by Hughlings Jackson and universally known as Jacksonian fits. The characteristics of these are that they start in a precise region of the body, always the same, and that they spread to other regions in a definite order, corresponding exactly to that in which the centres are arranged in the cortex. They may be preceded by twitching or tingling in the part, and they commence with a stage of tonic spasm, passing into a series of clonic jerks. Consciousness is only lost if the convulsions become generalised. The fits may occur at any interval, from months down to minutes, and a very important feature is that they are always followed by definite weakness in the portion of the body in which the fits started.

Cortical paralysis has equally striking features. It is essentially a paralysis of movements and not of individual muscles or even muscle groups. Stimulation of the centres in the motor cortex give rise to definite movements, such as flexion of the elbow or abduction of the arm, in each of which certain muscles contract with nicely balanced force, whilst other antagonistic muscles are relaxed in suitable degree. Destruction of the centre removes from the individual the power of initiating the movement concerned, and at the same time the removal of cortical inhibition and control compels the limb to take up a characteristic attitude. Thus, in a complete hemiplegia, where the whole cortical control is removed, the arm will take up a position of adduction, with flexed elbow, pronated forearm, and flexed wrist and fingers. The leg, on the other hand, will be adducted and extended at the hip, and extended at the knee and ankle. In partial lesions other attitudes may be adopted. In all cases the paralysis will be accompanied by an increase in tone in the muscles and by an increase in the deep reflexes.

The growth of a tumour pressing on the motor area will therefore give rise to a characteristic clinical picture, Jacksonian fits followed by weakness in the region of origin, and a steadily advancing paralysis. The latter spreads as before in accordance with the arrangement of the cortical centres, and thus presents certain peculiar features. It is not uncommon, for example, for the thumb centre to be first affected. In such a case a moment's consideration of the cortical plan will show why it is that the face may be affected before the shoulder, and that it will always be involved long before the leg. On the other hand, a lesion which starts in the toe area can only spread to the arm from the shoulder downwards, and not till the hand is involved can it reach the face.

There are other curious and distinctive features of a cortical lesion, depending on the fact that certain movements are not entirely under voluntary control and may be initiated from regions other than their proper centre in the contra-lateral precentral area. Thus it is typical of a cortical paralysis of the face that the frontalis and orbicularis palpebrarum should escape. This appears to be due to the fact that in general (and in some individuals invariably) these muscles act together on the two sides and have thus obtained a bilateral cortical control. Again, in a cortical paralysis of the face, though no voluntary movement of the lower part may be possible, it may be thrown into strong contraction on emotional disturbance, such as laughing. Neither of these phenomena could occur in a paralysis due to a lesion of the facial nerve itself, and they may thus be of great value in diagnosis. Similarly in cases where the trapezius is paralysed by a cortical tumour the upper portion can often be made to contract on deep respiration, a symmetrical though voluntary act.

Immediately in front of the precentral area lies the intermediate precentral area, in which it is probable that motion formulæ are constructed and retained and that the memory for skilled acts resides. Upon its integrity depends the accurate performance of actions which we have learned by practice to execute with facility, whilst its destruction, especially on the left side, may abolish the possibility of such acts, although there may be no paralysis in the ordinary sense. Such a condition is known as motor apraxia. By far the most important example is in lesions of the posterior extremity of the left inferior frontal convolution in right-handed individuals, the area of Broca, in which is stored the memory of those movements involved in speech. The loss of this area makes voluntary speech impossible, although the individual may know exactly the words he wishes to use and may be able to look them up in a dictionary. In the involvement of the area by a tumour these symptoms are diagnostic, but the area is of further importance to a surgeon, since whenever possible he will avoid its neighbourhood and will plan his explorations so as to leave it intact.

Immediately behind the fissure of Rolando lies the post-central area, second only in importance to the motor area itself. It is essentially a sensory area and in subdivisions and extent it corresponds exactly to the motor area in front of the fissure. From this, however, it is sharply differentiated by its histological structure, for the groups of Betz cells are absent and there is an additional granular layer. Sensory tracts may be traced from cell stations in the thalamus to terminations in this area, and it forms in fact the primary cortical receiving station for sensory impulses entering consciousness. The impulses reach this area in crude form, only capable of producing indiscriminate sensations, vague and badly localised. But it is here apparently that they cross the threshold of consciousness to be analysed, compared, and refined in other areas. Injury to this area may result in a loss of postural sense, of localisation, of tactile discrimination, of the perception of the degrees of heat and cold, and it is characteristic of such lesions that this loss should be irregular in its distribution and vary in the extent to which each element is affected. This peculiar sensory loss may be accompanied by a hypotonia of the muscles in the same region, due presumably to interference with the cortical reflex arc. Irritation produces a vague tingling in the corresponding area, and such a tingling is often the precursor of a Jacksonian fit commencing in that region of the body.

Just as in front of the motor area we have an area for the preparation of complex motor acts, so immediately behind the sensory area we find an area for the elaboration of sensory impressions, in which the crude impressions received by the sensory cortex are analysed, estimated, compared, and recorded. The highest portion of this area is devoted to stereognosis, and a lesion in this region may destroy the power of recognising objects by touch, of estimating form and weight, and of recognising the position of the limbs when blindfold. It is obvious that a tumour involving this region of the brain, causing paralysis at one point and irritation at another, may set up phenomena of great complexity and produce symptoms exceedingly difficult to unravel. But a further difficulty is added by the fact that the tumour may be either extra- or intra-cerebral, and that it may thus approach the cortex either from above or from below. Furthermore, the distinction is of the utmost importance to the surgeon, for in the first case the removal of the tumour may be easy, in the second it is probably impossible. The most important distinction is to be found in the order of onset of the symptoms. In cases where the tumour is cortical, symptoms of irritation will first appear, to be followed later by paralysis. In subcortical tumours the tracts are likely to be first involved and it may be only after a paralysis of some duration that signs of irritation become evident. But the distinction is by no means constant and there is no more difficult or uncertain point in cerebral surgery than the diagnosis between a cortical and a subcortical tumour.

Certain of these points are illustrated in the following cases :—

CASE 1.—A married woman, aged 25, was referred to me by Dr. R. A. Rowlands in October, 1921. For 18 months she had suffered from occasional morning headaches which had become more severe in the last two months, being now accompanied by vomiting. Seven weeks before I saw her she had an attack of numbness in the fingers of the left hand, spreading up the arm to the shoulder and also involving the left side of the tongue. She was unable to use the hand and had difficulty in speaking. The attack lasted three or four hours. Two days later a similar attack occurred, but lasted for a longer time, and a certain degree of numbness in the tips of the left index and middle fingers had persisted ever since. She was a healthy, well-developed woman, mentally alert. Her ocular movements were normal and her vision fair, but slightly blurred for distant objects. There was severe papillœdema of both discs and weakness of the lower portion of the left side of the face. The tongue was protruded to the left. Grip and wrist extension were weak on the left side, but all other movements were normal. On the left all the deep reflexes were increased, there was an upgoing toe, and the abdominal reflex was diminished. Sense of position was defective in the fingers and thumb of the left hand. A cortical tumour of the right Rolandic area was diagnosed.

Operation.—When an osteoplastic flap over the right Rolandic area was turned down, the dura was seen to be purplish in colour and under very great pressure. On opening it a large soft tumour appeared in the upper part of the aperture. A diffluent tumour about the size of a tennis ball and purplish in colour slowly oozed out. It was not attached to the brain in any way, and as it emerged the cavity in which it had lain became completely obliterated. The tumour appeared to have arisen from the inner surface of the dura, a considerable portion of which was removed with it. The osteoplastic flap was returned, no attempt being made to close the dura. The patient made a perfect recovery and has remained well ever since. Her sight is now normal and there is no trace of papillœdema.

CASE 2.—A girl, aged 12, was referred to me by Dr. Cecil Wall in January, 1922. For 15 months she had suffered from frontal headaches, accompanied by vomiting, and lasting about 24 hours. They were followed by a sensation of numbness in her left leg. Eight months ago the numbness became more marked, and there were occasional attacks of twitching in the leg, which later spread to the trunk, arm, and face on the left side. These attacks had now become frequent, occurring at intervals of one to six days, and always preceded by numbness in the left leg, starting in

REGIONS OF IMPORTANCE IN THE LOCALISATION OF INTRACRANIAL TUMOURS.

the toes. Since the onset of the numbness the headaches had practically disappeared. She was a well-nourished intelligent child, but dull and apathetic. She answered questions readily, but occasionally seemed to have some difficulty in understanding what was meant. The movements of the eyes were normal, but there was advanced papillœdema on both sides. There was full power in both legs, but movements were stiff and clumsy. The deep reflexes were increased on the left side, where there was also ankle clonus and an upgoing toe. The left abdominal reflex was absent. An endothelioma of the falx on the right side was diagnosed.

Operation.—A large osteoplastic flap was turned down over the right Rolandic area. The dura was found under high tension, and on opening it with a crucial incision the brain protruded under great pressure. As the consistency of the brain seemed to be firmer in the upper part of the opening an incision was made into the frontal lobe well in front of the fissure of Rolando. At a depth of three-quarters of an inch a firm tumour was discovered which proved to be an endothelioma arising from the falx. It was a firm spherical mass about the size of a golf ball, and was enucleated with ease. The operation was followed by a complete paralysis of the left arm, which, however, rapidly disappeared. The patient made a good recovery and has remained in perfect health.

TUMOURS INVOLVING THE VISUAL PATHS.

Visual sensations are conveyed to the cortex by paths so similar to those of somatic sensation that a comparison is both interesting and instructive. Sensory impulses from all parts of the body and of every kind enter the spinal cord by the posterior roots and are conveyed upwards in the various tracts. Some pass at once to the opposite side, whilst others pass up directly to the medulla and cross over in the decussation of the fillet. They then pass up through the contra-lateral crura to the ventral part of the optic thalamus and thence radiate out to the sensory post-central cortex. In a precisely similar manner visual sensations from the right and left visual fields are conveyed by paths which decussate in the optic chiasma, so that the sensations from each visual field are conveyed in the contra-lateral optic tract. Reaching the posterior pole of the optic thalamus, fresh fibres arise which radiate out to the occipital cortex around the calcarine fissure. Thus both sensation and vision enter consciousness through the cortex of the brain opposite to the side of their origin. In studying the effects of tumours upon the visual path we shall have to describe certain portions of that path in greater detail, and as it is especially at the chiasma, in the temporal lobes, and in the occipital region that accessible tumours affect the path, it is to these portions that I shall specially direct your attention.

The visual cortex is situated for the most part on the mesial aspect of the occipital lobe above and below the calcarine fissure. This fissure bears a precise relation to the visual fields, for below the fissure lies the receptive field for the lower half of the retina, above it for the upper. Thus an injury to the cortex below the fissure will affect the upper portion of the visual field, whilst the lower portion of the visual field is related to the upper cortical area. And as each occipital lobe is concerned only with the contra-lateral half of the visual field, injury to these portions of the cortex will affect only a quarter of the field, producing a quadrantic hemianopia. Such lesions have been described as the result of gunshot wounds, but it is rarely that the effects of a tumour will be so limited. In general, a tumour in this region will produce more or less complete blindness in the contra-lateral visual field.

Tumours in the occipital region may be intra- or extra-cerebral, and from the surgical point of view the distinction is an important one, as in the latter case the chances of a successful removal are far greater. The diagnosis is exceedingly difficult, but there are important considerations which may be of assistance. A cortical tumour is more likely to produce symptoms of irritation; never true pictures, for they are not stored here, but flashes of light, often coloured and suggesting fireworks. Those who are the subjects of migraine will be only too familiar with such visual effects, probably arising from vascular disturbances in the occipital cortex. As such a tumour spreads it will involve other regions of the cortex, and we may get symptoms from involvement of some portion of the sensori-motor area, such as numbness or paresis of the hand or face of the opposite side. A subcortical tumour, on the other hand, is less likely to give rise to symptoms of irritation, except in the not uncommon accident of a sudden hæmorrhage into its substance, when there will be other acute symptoms. But such a tumour is very likely to involve the posterior portion of the internal capsule at an early stage, since this is continuous with the optic radiations themselves. Now in this part of the capsule are collected at least a large portion of the fibres for common sensation, and just in front of these lie the motor fibres for the leg. Interference with sensation and with the movements of the leg on the opposite side may therefore be expected.

Some of these points are admirably illustrated in two cases described by Christiansen.

The first was a man of 41 who for three or four months had been in poor health, easily fatigued, and liable to occasional attacks of shivering. For two months he had had headaches, occipital and frontal, coming on with great violence, often at night, and accompanied by such giddiness that he once fell down. His memory had become poor. The man seemed very ill, his gait was uncertain and slightly reeling, but there was no definite incoördination nor changes in the reflexes nor in sensation. He had a definite right homonymous hemianopia. A few days later there was a slight weakness of the right face, followed in a short time by weakness of the right upper limb and early papillœdema. On exploration a large tumour was found arising from the dura mater over the left occipital lobe.

The other was that of a man of 37 in perfect health till five weeks before admission. Whilst at work he suddenly became conscious of a dazzling light before his eyes. He became giddy and fainted, and he remained unconscious for half an hour with slight convulsions of all four limbs. The attack was followed by no focal symptom, but by persistent headaches, recurring with extreme violence, and by repeated attacks of giddiness. He always thought that the first attack was coming on again, but he avoided it by lying down. For three weeks after the first attack he had diplopia, which then disappeared and did not return. He had also noticed that he could see nothing in the left visual field. He had slight left facial paresis of the central type. The left abdominal reflex was absent, and the left cremasteric reflex feeble. The other reflexes were normal. There was no loss of sensation or motor power and no ataxia. He had a left homonymous hemianopia. On exploration a large tumour was found in the right occipital lobe. It proved to be a cystic glioma and contained a large quantity of altered blood and cholesterin.

In each of these cases a large tumour developed silently. In the first it gradually gave rise to signs of general pressure, headache, and giddiness, but only at a late stage did signs of regional pressure appear. From that moment, however, they were progressive, spreading over the cortex till even the Rolandic area was affected, and hemianopia was followed by weakness in the right face and arm. In the second no symptoms arose until a sudden hæmorrhage into the substance of the tumour produced symptoms of acute cortical irritation from general pressure as shown by the convulsions, and a violent disturbance of the optic radiations, resulting in sensations of light. Had the tumour extended as deeply as the internal capsule sensory disturbances in the opposite half of the body and weakness in the opposite leg would have also appeared.

TUMOURS OF THE TEMPORAL LOBE.

Until quite recently the temporal lobe was regarded as one of the most silent portions of the brain, and tumours in this region were rarely diagnosed till a late stage. The investigations of Cushing have, however, supplied us with a syndrome of these tumours as fascinating as it is precise. Unfortunately these cases rarely present themselves till general symptoms have appeared, to mask the essential features of the syndrome. It was shown by Mayer in 1907 that the optic fibres which arise from the posterior extremity of the optic thalamus pursue a very definite course and maintain a very precise arrangement as they spread out to form the optic radiations, to end in the occipital cortex. Starting in an outward direction they flow over and around the descending horn of the lateral ventricle, passing backwards on its outer and inferior aspects. The ventral fibres thus make a long detour, whilst the dorsal reach the cortex by a shorter route, but the important point is that the two groups maintain their individuality, the ventral fibres conveying impressions from the lower portions of the retinæ and terminating below the calcarine fissure, whilst the dorsal fibres convey impressions from the upper portions of the retinæ and terminate above that fissure. But we have seen that each side of the brain is only concerned with the contra-lateral visual field. It follows that a tumour affecting the ventral part of the right temporal lobe may produce blindness in the upper left field, whilst a tumour affecting the dorsal part of the same lobe may produce blindness in the lower left field.

In the early stages, however, these defects may be only partial and can only be discovered by very accurate and minute perimetry. With the ordinary rough methods they are certain to be missed, and for this reason they have escaped notice. In later stages and with tumours far back the whole radiation will be involved and a complete hemianopia will result. If, on the other hand, the tumour is in the anterior part of the lobe the radiations may entirely escape. But even with these qualifications the sign is of the utmost value in fixing the site of a tumour hitherto obscure, and Cushing succeeded in demonstrating it in 25 out of 59 verified tumours of the temporal lobe.

The temporal syndrome includes another symptom of equal interest, occurring in those cases where a tumour affects the region of the uncus. It is a peculiar attack, lasting for a few seconds and possibly recurring many times a day. In it the patient feels dizzy, or even passes for a moment into a dreamy state, in which he may have hallucinations of smell, taste, hearing, or vision. The first two may be agreeable and may suggest scents or fruit, or intensely disgusting, in which case sucking movements of the lips and tongue may occur. The hallucinations of vision may be very extraordinary, such as a procession of black cats across the ceiling, or a little negress cooking. Occasionally a complicated scene is enacted. In any case the hallucination is always the same; it always occurs in the blind field, and it always disappears in this direction when any attempt is made to follow it. The essential symptoms of a temporal tumour are thus a quadrantic hemianopia and a form of petit mal, accompanied by peculiar hallucinations of smell, taste, or sight.

PITUITARY TUMOURS.

An entirely different type of hemianopia may be produced by tumours arising from the pituitary gland. This small gland lies immediately behind and below the optic chiasma, from which under normal conditions it is separated by the olivary eminence of the sphenoid bone. When, however, it is replaced by a tumour, this may produce a pressure before which not only the olivary eminence but the anterior clinoid processes may themselves disappear, whilst the tumour pushes forwards beneath the optic chiasma, lifting it up and stretching the optic nerves in a very remarkable manner. The pressure falls chiefly on the posterior and inferior portion of the chiasma, the precise part in which the fibres from the nasal portions of the retinæ decussate. The interference with these fibres results in blindness in the temporal fields on both sides, and we thus see how it is that *bitemporal* hemianopia is such a characteristic feature of tumours of the pituitary gland.

Occasionally the tumour may push the chiasma up in such a way as to compress its margins against the internal carotid arteries and a binasal hemianopia may result. But this is a rare occurrence. If, however, the tumour is left to grow the combined pressure on the chiasma and traction on the optic nerves will produce total blindness. Whether total or partial the blindness is accompanied by atrophy of the nerve, and the pale, shrunken disc is in striking contrast to the congested, swollen structure seen in the papillœdema which is so common a feature with other varieties of cerebral tumour.

With pituitary tumours the pressure effects are very localised, and we rarely find any indications of increase in the general intracranial pressure. From pressure on the floor of the third ventricle we may get somnolence and polyuria. Pressure on the uncus may give rise to typical uncinate fits, with the transient dreamy state and hallucinations of taste and smell. Paræsthesias in the face may arise from pressure on the fifth nerve or ocular palsies from the third. Headaches may occur, it is true, but they have a bursting character, are not accompanied by vomiting, and appear to be due to tension within the pituitary fossa, the absorption of whose walls can be readily demonstrated in an X ray photograph.

In a majority of cases pituitary tumours give rise to an entirely different group of symptoms from excess or defect in secretion. The gland consists of two portions, an anterior and a posterior lobe, each producing a secretion of vital importance, the excess or defect of which may give rise to phenomena of great complexity. Very briefly the results are as follows. Excess in the anterior lobe produces gigantism when it commences in childhood, acromegaly when it commences in adult life. Defect produces Lorraine's type of infantilism, with small body, small fine bones, asthenia, and loss of sexual characters. In the posterior lobe excess produces a high blood pressure, an excessively alert intelligence, and possibly glycosuria, whilst defect causes Fröhlich's syndrome, with excessive deposit of fat, loss of sexual characters, dull mentality, and high sugar tolerance. But even these complex syndromes rarely occur in a pure form, and the case may pass from one to another with the development of the disease.

ACOUSTIC TUMOURS.

All the tumours to which I have so far referred lie above the tentorium; as I have already mentioned, those which lie below it have very special characters to which I now wish to draw your attention. Of these tumours one of the most characteristic and important is that of the acoustic nerve. A small fibrous tumour of slow growth, it gives rise to symptoms out of all proportion to its size, whilst its removal will tax to the utmost the resources of the surgeon. These tumours are a peculiarity of the acoustic nerve, other nerves being similarly affected with extreme rarity. Their importance will be recognised from the facts that they form 6 per cent. of all intracranial tumours, that the injury they produce is purely mechanical, and that their successful removal means the complete and permanent cure of a patient who is otherwise doomed to blindness and a terrible death.

The first symptom is naturally unilateral nerve-deafness, often first noticed in using the telephone, and this may precede all other symptoms by many years. The vestibular portion of the nerve may also be affected at an early date, and giddiness may result. It is not, however, until a later stage, when the cerebellum is itself involved, that ataxia and vertigo become prominent symptoms. When they do occur they are accompanied by weakness of the lower extremity on the side of the lesion, with unsteadiness of gait and a tendency to fall to this side, and by a nystagmus with slow oscillations on looking towards the lesion. Soreness and stiffness of the neck are early features and may be due to stretching of the tentorium. Neighbouring nerves may be pressed upon or stretched, and we may find weakness of this side of the face or of the external rectus of the eye, or tingling in the distribution of the fifth nerve, with lowering of the corneal and palate reflexes on the same side. It is characteristic that all these effects should vary from time to time, whilst the deafness remains invariable.

But interesting as these symptoms are, they are trivial as compared with the general symptoms which arise as soon as the distortion of the pons has produced occlusion of the aqueduct of Sylvius and obstruction to the outflow of cerebro-spinal fluid from the ventricles. Headache, vomiting, dulling of the mental powers, and loss of vision from papillœdema may come on with a precipitancy comparable to that of the symptoms of acute intestinal obstruction, and the case may pass in a few days from one of academic interest to one of desperate emergency. The tumour actually lies in the lateral cistern of the arachnoid and is surrounded by a localised collection of fluid, a slight increase in which may at any moment determine the disaster. The pons is distorted, the aqueduct is blocked, the lateral ventricles become distended and force down the mid-brain, and the tentorium with the structures beneath it, so that the cerebellum may be driven into the spinal canal as far as the third cervical lamina, and the medulla be crushed with its vital centres.

No tumours show in sharper contrast local, regional, and general symptoms, and it is in this order that they appear. First we have the nerve-deafness of the eighth, and then the transient palsies of the seventh, sixth, and fifth nerves. Next the cerebellum is compressed and instability of gait, vertigo, and nystagmus appear. Finally, obstruction occurs and this small tumour produces all the classical symptoms of intracranial tension, headache, vomiting, and papillœdema, in an aggravated form. I have chosen it as a closing example as an epitome of the surgical pathology of cerebral tumours.

OPERATIVE TREATMENT.

A discussion of the details of operations on cerebral tumours would open too wide a field, but there is one point to which I should like to refer—namely, the use of local anæsthesia for these operations. The method is not yet in general use, but so remarkable are its advantages that I venture to think that its universal adoption can only be a matter of time. It is a very conservative statement to say that its use reduces by half the dangers and the difficulties of the surgery of the brain and spinal cord. The reasons for this will be made clear by an illustration.

CASE 3.—A man, aged 44, had suffered for some months from a steadily advancing paralysis affecting primarily the right leg, but spreading to the right arm and face, and interfering with speech. The diagnosis was made of a glioma of the left frontal lobe. Without warning he had a severe fit in which he lost consciousness and had general convulsions. This was followed by a marked increase in the spasticity and paralysis of the right side, complete loss of speech, complete paralysis of the lower face and tongue, and difficulty in swallowing. The man was very ill, but it was felt that some effort ought to be made to relieve him.

Operation.—After a preliminary injection of morphia gr. $\frac{1}{4}$ and hyoscine gr. $\frac{1}{150}$, the area of operation was anæsthetised by means of a 1 per cent. solution of novocaine, to which a small amount of adrenalin had been added. The line of incision, extending in a curve from the eyebrow to the mastoid process on the left side, was first infiltrated, then the injection was carried beneath the epicranial aponeurosis, and finally a deep injection was made into the left temporal fossa. About 100 c.cm. of solution were used. Half an hour later a very large osteoplastic flap was turned down, including the greater part of the left fronto-parietal region, four large trephine holes being joined by means of a Gigli saw. The dura was divided and a large area of brain exposed. The left frontal lobe was found to be very extensively involved by a glioma, the deeper portion of which had become cystic and had ruptured into the lateral ventricle, from which 30 c.cm. of turbid fluid full of débris were aspirated. As the brain was now under no pressure the osteoplastic flap was returned and the scalp sutured in the usual way. Throughout the whole operation the patient felt absolutely nothing, and, in fact, for the greater part of the time he was quietly asleep. Six small gauze swabs were used and one ligature (for the supraorbital artery), and the total loss of blood could not have been half an ounce. The only change was a slight quickening of the pulse-rate, which at the end of an extensive exploration lasting 50 minutes was 120, and of good volume. The patient made a steady improvement and in three weeks was almost as well as before the rupture of the cyst, walking with a little help and recovering his speech.

With local anæsthesia operations on the brain and spinal cord are practically bloodless, there is little or no shock, and the risk of respiratory troubles after the operations is minimised. During the operation there is no increase in vascularity or in intracranial pressure, such as are inevitable with general anæsthesia. The anæsthesia of the bone and of the dura appears to be absolute. The operation is conducted under conditions so ideal that, except to allow time for the extrusion of a tumour, there can rarely be any need for a two-stage procedure. The comfort of the patient afterwards is remarkable, and the attention he requires is greatly reduced. I believe that the use of local anæsthesia marks a very real advance in the surgery of the brain and spinal cord, and nowhere are its powers more remarkable or its advantages more apparent than in operations upon intracranial tumours.

A NOTE ON
MECHANICAL APEX TRACINGS.

By A. MOUGEOT, M.D. Paris,
CONSULTING PHYSICIAN AT ROYAT.

AT the beginning of 1923, when attending the course of cardiology at the National Hospital for Diseases of the Heart, London, I was much struck with the difference of opinion which exists with regard to mechanical apex tracings or cardiograms in France and England. I have thought, therefore, that it would be of interest to discuss the reasons why we, in France, consider that mechanical cardiography possesses a wide field of information and is of great symptomatological importance. It is not my intention in this article to compare mechanical cardiography with electrocardiography. The subject is too large and lies without the scope of the present paper. I would like to state that each has its importance and its place in cardiology and that the one supplements the other and can in no sense take its place.

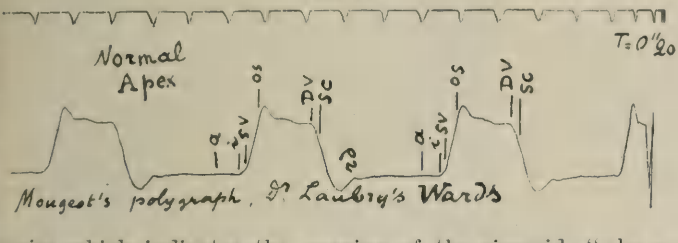
As shown by Pachon [1] in 1904, the apical tracing reproduces in an exact and faithful manner the curve of intraventricular pressure oscillations during the cardiac cycle. But, in order that this tracing may be compared or identified with the admirable curves obtained from large animals, such as the horse, by Marey and Chauveau [2] with intracardiac "sounds" or sounding pipes, by Hürtle with an elastic manometer, and by Piper with an optical pressure recorder, there is one essential condition: the patient must lie on his left side and the apex beat must be registered by means of a cardiograph with a button, lateral tube, and a screw to regulate the pressure of the button. Such a method answers the objections of Roy and Adami.[3] Care must always be taken to apply the button as accurately as possible, because, in some patients, the anatomical disposition (ribs, breast, emphysema of lungs, obesity) of the chest wall makes it difficult to obtain good contact between the impulse of the apex beat and the button of the cardiograph.

If so skilful a cardiologist as Sir James Mackenzie did not succeed in getting from apical tracings such good results as those we generally obtain, the explanation is to be found in the method employed—namely, the use of a funnel with the patients lying on their backs. This technique is wrong; the results were therefore irregular and the conclusions consequently unfavourable. It may seem very bold to differ in opinion from so great an authority as Mackenzie, whose work on the cardiac arrhythmias has so great a reputation in France as well as in England; nevertheless, I will endeavour to summarise the ideas underlying Pachon's technique and their importance in clinical work.

Pachon's Technique.

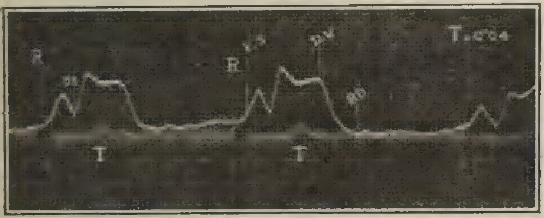
In the normal individual the apical tracings show, at the end of diastolic rest, a small elevation (*a*) which indicates the blood flow thrown into the ventricle by contraction of the auricle. Following this, a tall climb followed by a "plateau" designates the ventricular systole and shows the following details (Figs. 1 and 2). The first part (1) of the ascending line rises slowly; this is Chauveau's and Pachon's "intersystole"[4]—i.e., the preliminary contraction limited to the papillary muscle of the auriculo-ventricular valves. The massive contraction of the ventricular wall begins with the nearly vertical climb (*s.v.*) at the moment of the closure of the auriculo-ventricular valves, coinciding with the first heart sound, and continues until a half-moon shaped notch (*o.s.*), Chauveau's or Laubry and Pezzi's[5] *encoche semilunaire*, which indicates the opening of the sigmoid valves, is reached. From *v.s.* to *o.s.* the presphygmic period (*Anspannungzeit* in German, *temps de mise en tension* in French) is measured. At *o.s.* the expulsive period begins. The true beginning (*d.v.*) of the descending line marks exactly the initial point of the ventricular diastole. A notch early in the descending line marks the closing of the sigmoid valves. After the line has fallen below the abscissa corresponding to the initial point of the cardiac cycle, there is a diastolic jump (*r.d.*), Marey's *ressaut diastolique* at the moment of the opening of the auriculo-ventricular valves, and finally the line remains nearly horizontal (diastolic rest) until a new auricular wave appears and the following cardiac cycle commences.

FIG. 1.



From every point of view, in order to mark the a.c.v. undulations on jugular tracings, the cardiogram has a great superiority over the sphygmogram (Lian; Pezzi and Sabri).[6] By means of an ordinary stilette, tracings modified by a parabolic deflexion are obtained; but, registered by means of a double-jointed stilette with rectilinear movement (Mougeot)[7] or by optical projection, the true shape and character of the heart beat can be exactly figured.

FIG. 3.



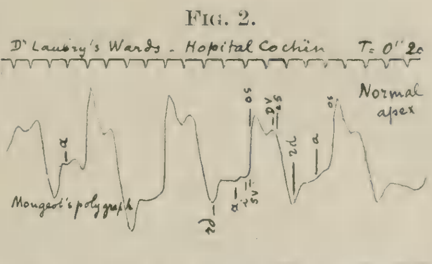
Optical registration of apex beat, combined with electrocardiogram in a case of left ventricle failure. Auricular fibrillation: *o.s.* notch extremely accentuated. Raising pressure period very long (0·36″).

Chronological Law of the Heart.

The morbid changes in the cardiogram have been studied by numerous investigators. We cannot do more than quote a few of these changes. The relative amplitude of the auricular and ventricular waves may be abnormal. In healthy subjects (*a*) is about 30 to 40 times smaller than the ventricular rise; but in gallop rhythm (*a*) is relatively much taller (Laubry and Mougeot[8]). In cases of high blood pressure, and in aortic patients, the *o.s.* notch becomes accentuated and much deeper; there is a round, vaulted shape of the systolic ventricular plateau when the overloaded ventricular muscle has difficulty in expelling its contents (Moulinié, Turlais[9, 10]). In cases of aortic regurgitation, the diastolic rest-line does not remain horizontal from *r.d.* to (*a*), but rises slowly, because the intra-ventricular pressure is increasing more rapidly before the auricular systole.

Further, numerous chronometric measurements can be obtained from apical tracings, on which we can determine easily and exactly the beginning and end of systole and diastole and divide up the presphygmic and the emptying periods of systole; thus we are enabled to reckon the duration of each part of the cardiac cycle. Normally, the ventricular diastole lasts five-eighths, or 63 per cent. to 67 per cent., of the total duration of the cardiac cycle. Such is the "chronological law" of the heart (Huchard, Gillet), which is greatly altered in morbid conditions. In most cases of tachycardia and heart muscle failure, diastole is shortened to 50 per cent. or even more of the cardiac cycle, so that both silences are of equal duration and "embryocardia" or fœtal rhythm occurs. The relative lengths of both parts in ventricular systole may be abnormal. But this point requires to be studied more in detail. If we consider the kind of work to which the different parts of ventricular systole correspond, it is possible in a cardiogram to attempt an evaluation of the functional capacity of the left ventricle and to estimate this capacity in cases of heart failure.

FIG. 2.



The Energometric Index.

The emptying period did not seem to me to be a good base for an energometric reckoning. According to Starling,[11] the formula which ought to be employed is: $W = Q\,R\,\frac{wV^2}{rg}$. The factor $\frac{wV^2}{rg}$ is negligible and the chief factors are Q (volume in c.cm. of blood expelled at each contraction) and R (the peripheral resistance). Unfortunately, in man we cannot measure accurately either the volume of expelled blood, or its velocity (V) when passing through the aortic orifice, or the exact sum of the peripheral resistances.

On the other hand, during the presphygmic period the cardiac work is purely static and consists in raising the intra-ventricular pressure from zero to a little more than the arterial diastolic pressure. With Laubry I have therefore adopted the formula, $\frac{\text{diastolic blood pressure} \times 13}{T^2}$ = energometric index, in which T is in hundredths of a second the duration of the ascending line on the cardiogram (0·10″ to 0·11″).[12] The minimal blood pressure (in cm. of mercury), taken at the arm, must be multiplied by 13, the specific gravity of mercury being about 13 times that of the blood. In normal subjects we find the energometric index to be very nearly 1. During our first experiments we found the index higher than 1 in hypertrophied hearts with good functional capacity and lower than 1 in patients with heart failure. Further researches will show us what importance can be attached to this energometric index or whether the formula must be modified.

To summarise, the apical tracing or mechanical registration of the heart beat taken by means of an adequate technique would seem to be a method of examination of great value, because it gives information concerning the cardiac contraction, the duration of each phase, the intra-ventricular pressure curve, and functional value of the heart muscle—points concerning which the electrocardiogram tells us nothing.

(*Continued at foot of next page.*)

BILHARZIASIS OF THE URETER.

By ALY BEY IBRAHIM, M.B.E.,
SURGEON, KASR-EL-AINY HOSPITAL, AND LECTURER ON CLINICAL SURGERY, SCHOOL OF MEDICINE, CAIRO.

Bilharziasis of the bladder has been fully observed and described by many writers, some of whom have drawn attention to the secondary effects produced on the kidneys and ureters by infiltration of the bladder wall round the ureteric openings. It is, however, far less widely recognised that, apart from the effect of bilharziasis on the bladder, there exists an infection of the ureters far more dangerous and intractable in its ultimate effects. Owing to the difficulty of observing changes in the ureter this has been very generally ignored during the life of the patients; the chief authorities on the subject devote only a few lines to it, and that chiefly from the pathological standpoint.

For many years surgeons practising in Egypt have been puzzled by the occurrence of typical cases of renal colic, in which the most careful radiographs of the kidney, ureter, and bladder have failed to show the presence of a stone. Some few of these are caused by pure uric acid calculi; occasionally one may be due to a Dietl's crisis, but the majority, probably nine out of ten, are due to bilharziasis of the ureter. In the same way most cases of hydronephrosis where no stone is found are really manifestations of the later stages of this disease and not secondary to disease of the bladder wall, to which they are so often attributed. This has been verified repeatedly on the operating table and post mortem.

I first described this condition in detail in the *Egyptian Medical Journal* in April, 1917. At that time I had met with over one hundred cases, all of which I had thoroughly examined and systematically investigated, and most of them I had followed in the different stages of the disease. When I wrote my article my object was merely to draw the attention of surgeons in Egypt to a very fatal and common form of bilharziasis which has received scanty notice in the literature. There was at that time little hope of influencing the progress of the disease. Now that bilharziasis can be successfully treated with tartar emetic, the outlook is far more hopeful, provided that cases can be recognised early. The latter point is an additional reason for drawing attention to this condition. The disease passes through three fairly definite pathological stages, each of which corresponds to a different clinical picture. It must be clearly realised that when the disease is bilateral, as it often is, two different stages may exist on different sides.

Morbid Anatomy (Figs. 1–3).

Bilharziasis of the ureter may exist apart from or in conjunction with vesical bilharziasis. It rarely affects the upper part of the ureter, the lowest 5 cm. being the site of election. Histologically the disease does not differ appreciably from bilharziasis of other organs.

Stage 1: *Infiltration with Bilharzia Ova.*—This manifests itself by the appearance of one or more of the following: (1) Sandy patches, (2) sessile infiltrations, (3) papillomata. At this stage the mucous membrane is still intact and the muscular wall in good condition. The kidney and pelvis usually appear quite normal. Occasionally a papilloma may act as a ball-valve, obstructing the flow of urine and producing in the corresponding kidney a hydronephrosis.

Stage 2: *Ulceration and Fibrosis.*—The ulceration is the result of necrosis of the mucous membrane covering the sandy patches and sessile infiltrations as well as of the falling-off of papillomata. The only mucosa left forms islets here and there, and the ulcers are covered with sloughs or incrustations of urinary salts. There is a round-celled infiltration gradually leading to fibrosis. Concomitantly with this, the muscular wall of the tube at the affected portion atrophies, being largely replaced by fibrous tissus. There is consequently a gradual narrowing of the lumen of the diseased part, and a secondary dilatation of the part above it. The pelvis of the kidney and its calyces are dilated too. The pyramidal area suffers from pressure atrophy, and eventually becomes narrower than the cortex, which does not seem to suffer until the next stage.

Stage 3: *Cicatrisation, Stricture, and Obliteration.*—The lumen of the affected part gets gradually obliterated until it is replaced by a mere solid fibrous cord. The upper part of the ureter gets more and more dilated and the kidney is eventually transformed into a fibrous sac with no remains of secreting tissue or mucosa. Such a sac contains urine or pus depending upon the absence or presence of infection. Infection, however, is a rare complication, unless the disease is accompanied by severe bilharziasis of the bladder.

Clinical Signs and Symptoms.

Stage 1.—The main symptom at this stage is renal colic, which I am inclined to attribute to the following causes: (1) Passage of blood clots produced at the lesion; (2) passage of sloughs, muco-pus, or urinary incrustations on the surface of the ulcers; and (3) passage of cast-off papillomata. The attacks last from a few hours to several days and disappear as suddenly as they start, the relief being usually accompanied by hæmaturia (with or without clots). These symptoms are repeated at variable intervals for some years, occurring at first on one side only, then they get less frequent on that side, appearing with the same intensity on the opposite side. During the attacks the kidney and ureter are tender, the latter particularly at the point of crossing the pelvic brim. Between the attacks the patient is usually in good condition, and on palpation no abnormality can be detected. The urine is usually highly acid, containing a variable amount of blood and bilharzia ova, otherwise its constituents are not altered. If the patient is cystoscoped at this stage, several papillomata may be seen on or adjacent to the ureteric opening. The opening itself will be seen contracting regularly, and the jets are strong and may be bloody. Less commonly, a large cauliflower-shaped papillomatous growth hides the opening from view. Passing the ureteric catheter is extremely difficult in all cases, since the papillomata form a sort of rampart over which the tip of the catheter slides, making accurate alignment almost impossible. The following cases illustrate this stage of the disease:—

Case 1.—Male, aged 25, complained of symptoms of renal colic, first on left side, then on right. Attacks remained six or seven hours, sometimes as long as two or three days. Urine contained albumin, red blood corpuscles, and white blood corpuscles. Bilharzia ova. X ray examination negative; cystoscopy showed bilharzial papillomata around ureteric opening; bladder otherwise normal. Symptoms improved slightly on the administration of alkalies. Condition the same six months and one and a half years afterwards. Patient then lost sight of.

Case 2.—Male, aged 19, complained of repeated attacks of renal colic on both sides. Urine contained albumin

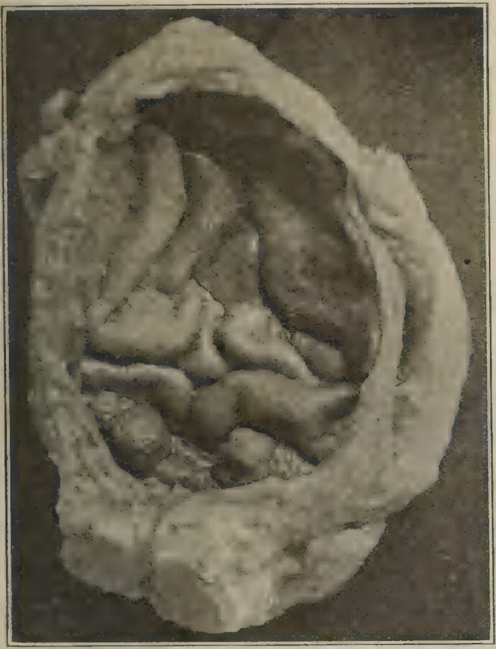
blood, and pus. X ray examination, of kidneys only, negative. Cystoscopy showed bilharzial papillomata around left ureteric opening, though jet of urine was strong. Right ureteric opening tumefied, and jet poor. Ureteric catheter could be passed up ureter only for 2 cm., and could not be passed at all up the left ureter. X ray examination of the ureters later showed a stone in ureter near bladder. Two months later patient passed a stone similar in shape and size to the shadow in the X ray plate.

FIG. 1.



Bilharziasis of ureter. Bladder (two-thirds natural size) showing two bilharzial papillomata surrounding the ureteric openings.

CASE 3.—Male, aged 27, complained of symptoms of renal colic on either side. Urine showed bilharzial ova. X ray examination negative. Cystoscopy showed bilharzial papillomata around both ureteric openings. A week later patient passed a small uric acid stone and subsequently two others.

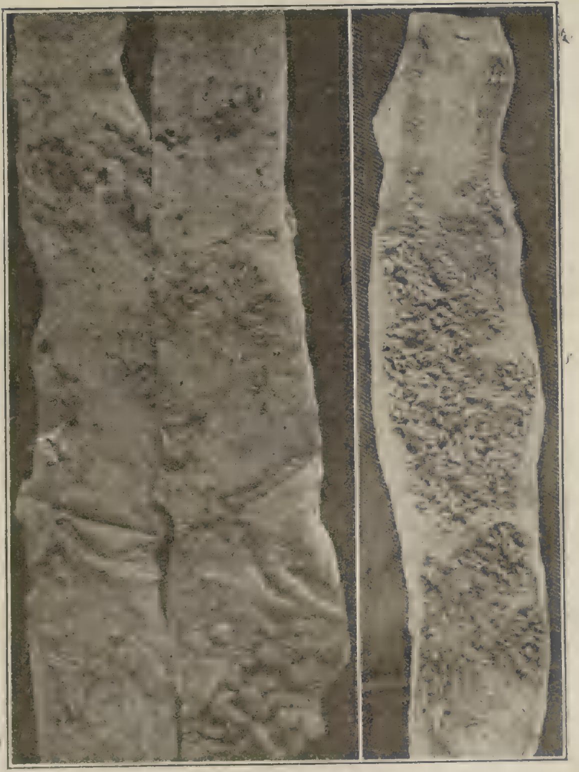
Stage 2.—The symptoms at this stage depend upon whether the urinary system is infected with bacteria or not. In non-infected cases the attacks of renal colic are replaced by a constant dragging pain in the loin which increases on any exertion. The patient becomes weak and anæmic, and complains of anorexia and headaches. On examination one or both kidneys are found enlarged and tender. If both are felt, one is usually larger than the other, the larger kidney being, as a rule, the one less affected. The total amount of urine is decreased, but every now and then the patient may pass large amounts. The specific gravity is low, 1007–1012. All constituents are diminished, urea decreasing to 8–12 g. in the 24 hours. Red and white cells are present, but tubular casts usually absent. Bilharzia ova may or may not be found. It is surprising how large numbers of cases can drag along in this state for two or three years considering their general and renal condition; one would not give them more than a few weeks to live. In infected cases the pain and tenderness are much more severe. There is an evening rise of temperature and pus is present in the urine. The patient looks much worse, loses weight very rapidly, and the final issue occurs earlier. Cystoscopy at this stage shows a patulous, immobile ureteric opening, out of which the urine flows in a continuous stream under very little pressure. Round the lips of the opening may be seen small ulcers with greyish, sloughy bases. The following cases illustrate this stage of the disease.

CASE 4.—Male, aged 60, complained of repeated attacks of renal colic during the last 12 years. Lately continuous dragging pains in both loins, general weakness, emaciation, and anorexia. Left kidney swollen and hydronephrotic. Urine: Sp. gr. 1007, urea 6 g. in 24 hours. X ray examination negative. Cystoscopy showed ulcerations and muco-purulent matter round the ureteric openings; mucous membrane of bladder in a state of chronic inflammation. Left kidney was tapped in the loin and 2 litres of fluid withdrawn. Patient was relieved after this, but returned a month later in the same condition; tapping was repeated, and 1½ litres of fluid withdrawn, but his general condition was now bad. He returned again a month later, his condition being still worse. I lost sight of him after this.

CASE 5.—Male, aged 45, complained of attacks of renal colic on either side during the last 30 years. Terminal hæmaturia. No stones passed. Seen two years later: condition then as follows: Continuous dragging pains and fullness in left lumbar region; marked weakness and anæmia and evening rise of temperature; a large, tender swelling occupying left lumbar region. Urine: Sp. gr. 1013, contained pus, urea 12 g. in 24 hours. X ray examination negative. Cystoscopy showed the mucous membrane of bladder in a state of chronic inflammation, opening of right ureter could not be seen, opening of left ureter covered up with muco-purulent matter. Diagnosis: Left pyonephrosis. Condition of right ureter could not be determined. Pyonephrosis incised from back and drained; nearly 2 litres of pus were withdrawn. Condition improved, but subsequently became worse, and he died one year later.

Stage 3.—The patient now passes into a condition of chronic uræmia. He usually comes with a huge swelling in each loin. Sometimes one or both ureters can be felt dilated, a matter of no great difficulty, as the patient is by now very much emaciated. Suddenly complete suppression sets in, and the patient succumbs two to four days later in a condition of coma. He may have a few twitchings, but convulsions are always absent. On cystoscopy one of two appearances may be recognised. Either a patulous, non-contracting ureteric opening with no

FIG. 2. FIG. 3.



Two examples of bilharziasis of ureter. Fig. 2 shows dilatation, and, in the lower part, bilharzial papillomata (about five-sevenths natural size). Fig. 3 shows dilatation and ulceration of mucous membrane (about two-thirds natural size).

urine flowing from it, or the opening may be so drawn up by contraction of the ureter that all that is seen in its place is a small funnel-shaped depression. The following cases illustrate this stage of the disease.
